Mr. Hayes moved that Mr. H. N. Draper, F.C.S., be elected Vice-President. He did not question for a moment the high qualifications of Mr. Payne, but he was convinced that it was essential for the interests of the Society that the Vice-President should be resident in Dublin, and always at hand to give the President any assistance that he required. Mr. Draper was one of the examiners of the Society, and from the beginning had taken the greatest interest in it.

Mr. Simpson seconded the motion, expressing his concurrence in the necessity for the Vice-President being resident in Dublin, and saying that he was sure Mr. Draper, if elected, would most efficiently perform the duties of the office.

Dr. Montgomery said if Mr. Draper accepted the office the Society would be most fortunate.

Sir George Owens said he would be delighted to pay any compliment he could to Mr. Payne, but he quite agreed with what had been said as to the necessity for having the Vice-President of the Society on the spot.

Mr. Hodgson said he had the highest possible respect and esteem for Mr. Payne, but was convinced that the Vice-President ought to be resident in Dublin

Professor Tichborne said an additional reason for electing Mr. Draper was that he had been appointed delegate of the Society to attend the international meeting of pharmacists to be held next year in Brussels.

Mr. Grindley said that as he saw so general a feeling in favour of Mr. Draper, he thought he would be doing what would be most in accordance with the feelings of Mr. Payne by withdrawing that gentleman's name.

Mr. Draper was then declared duly elected Vice-President, and expressed his sincere thanks to the members for their kindness in electing him. So far as his own personal feelings were concerned he would have liked to withdraw his name in favour of Mr. Payne, not only because he was convinced that that gentleman would have made an excellent officer, but also because he would have represented their friends in the North, who were a large and important body.

On the motion of Mr. Wells, seconded by Mr. Minchin, Mr. Hodgson was re-elected Treasurer

Mr. Hodgson said he was very much obliged to the Society. As long as he was the Treasurer he would do all in his power to keep the expenditure within limits

On the motion of Sir George Owens, seconded by Mr. E. M. Hodgson, Mr. Hugh Fennell was re-appointed Registrar.

Messrs. Allen and Hayes were re-elected Auditors.

On the motion of Mr. Grindley, seconded by Mr. Wells, the following were elected the Law Committee:—Professor Tichborne, Dr. Collins, Messrs. Allen, Hayes, Payne, Minchin, and Dr. Whitaker.

On the motion of Mr. Batt, seconded by Mr. Draper, the following were selected as the Certificate Committee:—Professor Tichborne, Drs. Collins and Montgomery, and Messrs. Payne, Allen, and Hayes.

On the motion of Mr. Minchin, seconded by Mr. Simpson, the following were appointed the Pharmacy Act Amendment Committee:—Messrs. Payne, Allen, Hayes, Drs. Collins and Montgomery and Professor Tichborne.

Professor Tichborne moved "That the *Pharmaceutical Journal* be supplied to the members, as heretofore, during the forthcoming year." Last year he observed that a number of gentlemen, after having received the Journal for a considerable time fell into arrears, and when pressed to pay up their subscriptions did not do so. Without discussing the question as to whether such a course was honourable or not, it was evidently injurious to the Society, and in order to meet the mischief he got the Council on February 7, 1883, to pass a resolution to the effect that when a member did not pay up his subscription within a reasonable time the supply of the Journal to him should be immediately stopped, but that he could afterwards get back numbers on paying up his subscription. On April 4, two months afterwards, Dr. Aquilla Smith moved and carried a resolution that at the expiration of the present year the Journal should be stopped altogether. He (Professor Tichborne) happened to be absent when that resolution was brought forward; had he been present, he would have opposed it. In the first place it prevented the remedy which he proposed from getting a fair trial. His remedy would not only have prevented the waste of money, but would have operated as a kind of feeler to see how far the Journal was an inducement to gentlemen to subscribe to the Society. He thought the question one for the general meeting of the Society, and accordingly he had brought it forward. He was, however, sorry to see that there were only three members of the Society present, in addition to the members of the Council. He maintained that the state of the accounts showed that the Society had the means of continuing the Journal, although, even if were otherwise, he did not think the cost of the Journal was the point at which they should begin to retrench. It would be better to increase the subscription to £1 5*s*. and continue the Journal. Again he was quite sure that the proceedings would not be adequately reported if the Journal were stopped as the organ of the Society. Dr. Aquilla Smith's argument was that pharmacists should subscribe for the honour of supporting the Society. He (Dr. Tichborne) did not believe they would, and he was convinced that if the Journal were stopped the subscriptions would very soon fall away.

Mr. Grindley said he had great pleasure in seconding the motion. He was the only member of the Council who voted against Dr. Smith's motion. Subscribers to the Society would have no means of knowing anything about its proceedings except through the Journal.

Mr. Hodgson said he never saw the wisdom of the original plan of supplying the Journal as an inducement to pharmacists to join the Society. On the other hand, he knew that men in the country were proud of being able to put M.P.S.I. after their names, for the privilege of doing which they had to pay their guinea. He failed to see the necessity of spending a large sum of money on the Journal in order to induce men to join the Society. Last year the Society had to pay £34 13*s.* 4*d.* for the Journal, besides £13 13*s.* for reporting its proceedings; so that all that remained out of the £53 11*s.* subscriptions, which were received from fifty-one members, was the magnificent sum of £5 3*s.* 8*d.* Was it, therefore, in accordance with common sense to continue the outlay? Since he came into the room he had ascertained that there was a large account due to the printers, of which he had previously known nothing. Again, he did not see why the original members of the Society should continue to derive any advantage from their position; and it was his intention to give notice of a motion that they should pay the same annual subscriptiou as the other members.

Mr. Hayes said the only way of ascertaining the feeling of the licentiates with respect to the Journal was to send out a circular asking them whether they would continue to subscribe to the Society if they did not get it. There was no doubt that it was necessary to curtail the expenses of the Society as far as possible.

Dr. Montgomery thought it might be well to try the experiment of stopping the Journal. He did not think it would make much difference if a few members did leave the Society on that account. Any surplus funds that the Society had should be laid out in prizes. He did not think it would be wise to send out such a circular as Mr. Hayes suggested. As to adding 5*s.* to the amount of the subscription it was a proposal that would require a great deal of consideration.

Mr. Simpson did not think it would be well to stop the Journal at present.

The President said he was originally in favour of giving the Journal; but having seen the number of members decline year after year, he thought it would be a mistake to keep matters on the present footing. Some means might be taken of ascertaining the wishes of the licentiates on the subject, or an attempt might be made to get the Journal for members at a reduced rate and so induce them to take it. It would be a loss to the Society if the reports of the proceedings in the Journal ceased. There was an omission in the reporting recently, and he heard several complaints about it.

Mr. Fennell, in reply to Professor Tichborne, said the cost of the Journal was 11*s.* 10*d.* for each member, including postage.

Professor Tichborne said he would alter his resolution so as to read "That the Journal shall be supplied for the ensuing six months." In the meantime a committee might be appointed to try if there was any way of reducing the cost of supplying it. As to the original members there were only four of them left on the Council, of whom he was one, and he had for many years paid much more than the amount of the subscription to the Society.

The resolution as altered, viz., "That the Journal should be supplied for the ensuing six months," was then put and agreed to *nem. con.*

The proceedings then terminated.

Provincial Transactions.

OLDHAM CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

At a meeting of the above Association, held in the room, Church Institute, on Thursday evening, September 27, Mr. Martin, President, in the chair, Mr. B. Swinbourn read an interesting paper on "Alcohol." The paper was well illustrated by diagrams and experiments, and, whenever necessary, by chemical equations of the various reactions.

After some remarks from Messrs. Martin and Buckley, a vote of thanks was proposed by the latter, which, having been seconded in a few appropriate words by Mr. Smith, was unanimously agreed to.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

(*Continued from page* 238.)

Upon re-assembling after luncheon, the first paper read was—

Second Report on the Differences between the Essential Oils of Cinnamon and Cassia.

BY ALFRED H. JACKSON, B.SC., M.P.S., F.C.S.,
Associate of the Owens College, Manchester.

In the first report, printed in the 'Year-Book of Pharmacy' for 1882 (pp. 395–400) and in the *Pharmaceutical Journal*, etc., it was shown that the relative density of cinnamon was 1·0097, whilst that of cassia was 1·0366; also that the specific refractive energy of cinnamon was ·32102, whilst that of cassia was ·28685.

Residue (1).—Some experiments were made upon this substance, which had been formed by passing steam through uncombined mixtures of cassia and potassium bisulphite solution. It had a brown colour, a sweet taste, with a trace of saline bitterness; it did not rotate the plane of polarization, though it reduced Fehling's solution slightly, and more abundantly after boiling with dilute sulphuric acid; thence its sweetness cannot be assigned with certainty to the presence of a saccharose, as the Fehling's solution may have been reduced by the benzaldehyde, the presence of which was revealed by its odour, and the source of which was probably due to oxidation of the cinnamaldehyde. Some of the residue was evaporated to dryness and treated with ether, but none dissolved therein. On treating with methylated spirit a small portion entered into solution; the alcohol was evaporated off, leaving a yellow residue, soluble in water, but having a more bitter taste than the original residue, thus showing that it was not identical with it. The source of the sweetness of this residue is interesting, because it may be the same as that which gives sweetness to the essential oils.

Bertagnini's Method.—(*a*) *With Alcohol.*—In the first report it was stated that the white magma, resulting from the combination of cinnamaldehyde with potassium bisulphite, was washed with methylated spirit. This alcoholic filtrate was distilled with sodium carbonate; also by passing steam through. To the distillates sodium chloride was added, but no change or separation of alcoholic from aqueous solutions was observable, and no oil was recoverable.

(β) *With Petroleum.*—The action of American petroleum spirit (b.p. 80°–90°) was then tried. The essential oils were each shaken up with a large quantity of the spirit, and boiled; they dissolved, but mostly separated out again on cooling. On shaking some of the petroline solution of oil with the aqueous solution of potassium bisulphite, no satisfactory combination was effected.

(γ) *With Ether.*—Oil of cassia was shaken up with a potassium bisulphite solution, the mass thrown on to a filter and washed with ether until a mass of pearly-white crystals was left on the filter. The filtrate consisted of a lower layer of watery solution of potassium bisulphite, and an upper one of the ethereal solution. The ethereal solution was decanted, and the ether distilled off on a water-bath; the oily residue was then treated again with $KHSO_3$ solution, and the process repeated about a score of times, until no more precipitate was formed with the $KHSO_3$ solution. This oily residue (2)—oil of cassia deprived of cinnamaldehyde—was dried with $CaCl_2$ and distilled:—1st, distilled under 100°, a few drops of a pale yellow, sweet, pungent oil, like cinnamaldehyde; 2nd, distilled about 260°, a few grams of a dark-brown, sweet, smoky, pungent oil; 3rd, distilled at 280°, a few grams of a dark-brown, bitter, smoky, pungent oil. There was a burnt, acrid smell, and a charred mass in the retort, showing eremacausis. These two distillates were similar to the sixth distillate from the original oil.

Oil of cinnamon was then treated similarly with the $KHSO_3$ solution. Its oily residue (3) had a brown colour distinct from that of cinnamon, with an aromatic smell akin to that of clove. An attempt to determine its boiling point showed that it was not a simple body; for, on distillation it began to boil at about 200°, rising to 250°, leaving a waxy residue and decomposing at 260°. There was not a sufficient quantity at disposal for a fractionation to be made. Tested with concentrated sulphuric acid it showed a brownish-red colour; an addition of water then turned it into a light mass of greyish-white resinous matter. Although residue (3) had ceased to give any precipitate with $KHSO_3$ solution, yet to find out whether it were quite free from cinnamaldehyde, the following tests were applied. A solution of magenta chloride was decolorized by $KHSO_3$ and SO_2; its violet-red colour was at once restored by the essential oil, but not until after a long time—and then but very faintly—by (3). A more delicate test was the addition of some HCl and KNO_2 to sodium sulphanilate; to the solution of this diazobenzene-sulphonate, made alkaline by NaOH, some of the essential oil—made alkaline—was added, and a violet-red colour was developed; a similar result followed the substitution of (3) for the essential oil, thus showing that (3) still contained a very small quantity of cinnamaldehyde. From two analyses of the ultimate composition of residue (3) the following results were got:—

Residue (3)	CO_2	H_2O	C	H
·192	·525	·156	74·57 %	9·02 %
·2515	·689	·211	74·75 %	9·32 %

Mean percentage, C, 74·66 and H, 9·17.

But, as the determination of its boiling point shows that it is not a simple substance, a formula cannot be deduced from these results.

Thus this method of separation does not yield sufficiently definite results to cause one to use larger quantities of so costly an oil.

Having a small sample of the pure oil of cinnamon left, it was burnt with the following results:—

Oil of Cinnamon	CO_2	H_2O	C	H
·292	·842	·1795	78·64 %	6·82 %
·1945	·568	·124	79·64 %	7·08 %
·374	1·09	·2335	79·5 %	6·93 %

Mean percentage, C, 79·26 and H, 6·94.

A comparison of this result with the analysis of (3) shows that the elimination of cinnamaldehyde alters very distinctly the composition of the oil, and so far justifies the use of Bertagnini's process as a good one, though not delicate enough for the end in view in this research.

In conclusion, I have pleasure in acknowledging the kindly suggestions of Professor Schorlemmer during this work.

The PRESIDENT said he feared the author would not get the credit he deserved, because, like many Alpine and Himalayan climbers, he had not reached the actual summit of either of the mountains of difficulty he had so courageously attacked. He had, however, opened out and extended the track, so that either he himself, or some other worker, at some future time would be able to follow in his footsteps, and would find the road less laborious than it was before. For that work he was thoroughly entitled to the thanks of the Conference.

The next paper read was on—

THE BITTER PRINCIPLES OF NERIUM ODORUM.

BY H. G. GREENISH, F.I.C.

As a grantee of the British Pharmaceutical Conference, I have to report the progress I have made in the isolation of the bitter principles of the nerium odorum, or sweet scented oleander.

For a supply of the root, my best thanks are due to Dr. Dymock, of Bombay.

After a number of experiments, I found the following method the most convenient.

The powdered root is moistened with distilled water, packed in a percolator, and percolated with water until exhausted. It is possible thus to free the powder from every trace of bitterness. The percolate is shaken with chloroform until free from bitterness; this point is easily ascertained by warming a little of the supernatant liquid to expel the chloroform, and tasting. Although apparently free from bitterness, the aqueous liquors may still contain a small quantity of the bitter principles in solution and this may be proved by concentrating to a small bulk and again shaking with chloroform; the yield will not, however, repay the trouble.

The chloroformic solutions are mixed and shaken with water made alkaline with caustic soda as long as the latter is coloured brownish or yellow; a final washing with pure water removing any traces of caustic alkali. The greater part of the chloroform may then be recovered by distillation at a gentle heat. The remainder is allowed to evaporate spontaneously at a temperature of about 100° F.

The resulting yellow substance is dissolved in warm spirit. Should it still retain traces of chloroform, the solution must be well stirred until they are dissipated, as otherwise the subsequent operations are much impeded. To the warm alcoholic solution about four volumes of hot distilled water are added, and the whole allowed to cool. A mass of minute crystals separates which can be filtered off and washed with weak spirit; the operations of recrystallizing and washing are repeated until the crystals are obtained snow-white and quite pure.

The mother-liquor from the first crop of crystals is diluted with more water and allowed to stand twenty-four hours. Should any more crystals separate they are filtered off. The filtrate is then shaken with chloroform until exhausted, and the chloroformic solution evaporated to dryness. The residue is subjected to a repetition of the process. The final result is a pale yellow amorphous mass which, when quite dry, is easily reducible to a nearly white powder. It should dissolve entirely and easily in spirit. Should the addition of water be followed by the appearance of a precipitate soluble in caustic soda or potash with a deepening in colour, the substance is contaminated with resin. It should be dissolved in spirit, the solution diluted with water, made alkaline with caustic soda and exhausted by shaking with chloroform. The chloroformic solution will yield the purified substance on evaporation.

Although both the bitter principles are freely soluble in spirit, I prefer extracting them from the root with water as the subsequent manipulations are thereby much facilitated. The process is an advantageous one inasmuch as the substances are not brought into direct contact with either alkali or, indeed, any substance likely to produce decomposition, nor are they subjected to the action of heat but for a comparatively short time.

One of the substances, the crystalline one, is possibly identical with a crystalline substance which I formerly* considered to be a decomposition product of the bitter principles; the other, the amorphous, represents the nerioderin in a state of greater purity.

I am now preparing the substances in larger quantity, and purpose reporting on their composition and properties at the meeting of the Conference next year.

The PRESIDENT said it would be remembered that some years ago Mr. Greenish obtained two principles from this Indian perfume and poison—which he called neriodin and nerioderein—neither of which, however, he succeeded in crystallizing. He had now crystallized the one, and ibtained the other in a less impure condition than that on which he obtained it before. For this work he was entitled to the thanks of the Conference, and it was to be hoped that he would continue his investigations into these substances. The Conference was also much indebted to Professor Dymock, of Bombay, who was always ready to assist in such investigations.

A vote of thanks having been passed to Mr. Greenish and Professor Dymock,

Mr. NAYLOR asked whether it was the fact that both these principles were bitter, or only the amorphous one, and also whether they were both to be regarded as neutral, or whether that was still undecided. He thought it very improbable that the crystalline principle separated could be regarded in any sense as a decomposition product, especially having regard to the mode of extraction.

Mr. BENGER said both principles were stated to be bitter.

The following two papers were then read:—

THE QUANTITATIVE SEPARATION OF STRYCHNINE AND BRUCINE.

BY WYNDHAM R. DUNSTAN,
Demonstrator of Chemistry,
AND F. W. SHORT,
Assistant-Demonstrator of Chemistry,
in the Laboratories of the Pharmaceutical Society.

The complete separation of the alkaloids of nux-vomica has always been a matter of great difficulty, and the processes which up to the present time have been used for the preparation of the pure alkaloids are quite unsuited for quantitative application. In fact there is no direct method for the separation of strychnine and brucine which gives concordant quantitative results. Professor Dragendorff† came to this conclusion after an examination of published methods and after many trials of methods of his own suggestion, finally recommending the employment of an indirect method involving the titration or precipitation of the mixed alkaloids with a solution of potassium mercuric iodide. In the face of the above facts we made an examination of the solubility of many salts of strychnine and brucine with the view of devising a direct method for the quantitative separation of the two alkaloids. Among the salts which we prepared were the ferrocyanides of strychnine and brucine, which were obtained in the first place by the double decomposition of the alkaloidal sulphates and potassium ferrocyanide. These salts were found to differ so considerably in their solubility that we commenced a full study of their properties and solubility under various conditions. A detailed account of this work here and now would be of secondary interest; it is, therefore, reserved for a future communication, and that portion alone dwelt upon that relates to the main problem, namely, the quantitative separation of the two alkaloids.

* See *Pharm. Journ.*, [3], xi., 873.
† 'Die chemische Werthbestimmung,' p. 65, *et seq.*

The first series of quantitative experiments were made with neutral solutions of strychnine and brucine sulphates, but the results obtained showed that the separation was not so complete as might have been anticipated from a separate examination of the aqueous solubilities of strychnine and brucine ferrocyanide. For this had shown that while strychnine ferrocyanide is but very slightly soluble in water, the similar salt of brucine might be termed a soluble salt. Now it was evident that in presence of brucine, strychnine ferrocyanide was not wholly precipitated from neutral solution. The next experiments were made in solutions which were decidedly alkaline with ammonium hydrate, and here the results showed that the separation, although much more complete than in neutral solution, was far from perfect. It may be worth while to record one or two of these experiments. A weighed quantity of the anhydrous alkaloids was dissolved in dilute sulphuric acid, solution of potassium ferrocyanide added and then ammonium hydrate until the solution was distinctly alkaline, the precipitate was filtered off and washed with a little dilute ammonium hydrate. From the filtrate and washings the brucine was recovered by agitation with chloroform after excess of ammonium hydrate had been added; in these two experiments the strychnine was determined by difference.

TABLE I.

	Taken.	Found.
Strychnine	0·071	0·068
Brucine	0·053	0·056
Strychnine	0·077	0·067
Brucine	0·104	0·114

Experiments were now made in which the alkaloids were dissolved in a slight excess of sulphuric acid, so that the solution before the addition of potassium ferrocyanide was distinctly acid in reaction. From such a liquid as this it was found that strychnine was wholly precipitated, while brucine remained in solution. After a great number of experiments relative to the influence of (α) *concentration and the proportion in which the alkaloids are present*; (β) *acidity*; (γ) *time*; (δ) *temperature*, we have succeeded in devising an entirely satisfactory method for the quantitative separation of strychnine and brucine. The inferences from these experiments may be summed up as follows:—(α) Strychnine is entirely precipitated by potassium ferrocyanide from a solution acidified with sulphuric acid, both alone and in presence of brucine, even when only 0·0015 per cent. of anhydrous strychnine is contained in the liquid (*cf.* Tab. III.). Brucine alone is not precipitated under similar conditions until the strength of the solution nearly approaches that of saturation and then the salt is slowly precipitated in large silky needles entirely differin in appearance from the granular and heavy precipitate of the strychnine salt. In presence of strychnine, however, brucine is precipitated more or less completely from sulphuric acid solution by potassium ferrocyanide if more than 0·06 per cent. of brucine is present; this is shown by the following results:—

TABLE II.

	Taken.	Found.
Strychnine	0·0878	0·1206
Brucine	0·2288	0·1900
Volume 200 c.c.		
Strychnine	0·0930	0·0942
Brucine	0·0576	0 0540
Volume 100 c.c.		
Strychnine	0·003	0·050
Brucine	0·100	0 053
Volume 150 c.c.		

Tested by the nitric acid reaction the strychnine residues contained much brucine. (β) Strychnine is more completely precipitated from a sulphuric acid solution of the sulphate than from a solution of the chloride or acetate acidified with the corresponding acids. The quantity of sulphuric acid present should never exceed 0·5 per cent. by volume of H_2SO_4, the most favourable proportion is 0·25 per cent. by volume. Excess of acid causes decomposition of the potassium ferrocyanide and promotes other secondary reactions. (γ) The time required for complete precipitation depends upon the quantity of strychnine present; the precipitation is greatly facilitated by vigorously stirring the sides of the vessel with a glass rod. When this is done and precipitation occurs at once it is usually complete in three or four hours. A solution containing 0·001 per cent. of strychnine is entirely precipitated in six hours. (δ) Rise of temperature above the normal should be avoided; when the solution is heated partial decomposition of the potassium ferrocyanide takes place.

Taking into account the above facts we propose the following method for the quantitative separation of the alkaloids. Any quantity less than 0·2 gram of the mixed alkaloids is dissolved in about 10 cubic centimetres of a 5 per cent. (by volume) solution of sulphuric acid (=0·5 c.c. H_2SO_4), the solution is diluted to about 175 c.c. with water and then made up to 200 c.c. with a 5 per cent. solution of potassium ferrocyanide. The liquid is transferred to a beaker, stirred occasionally and allowed to stand from three to six hours. The precipitate is filtered off and washed with water acidulated with sulphuric acid (about 0·25 per cent.) until the washings are free from bitterness. As the precipitate is liable to alteration upon drying it is decomposed by the addition of a strong solution of ammonium hydrate, the filter washed with the same liquid and finally with chloroform, a sufficient quantity of which is used to entirely extract the alkaloid from its solution in ammonium hydrate. The chloroformic solution is then evaporated and the anhydrous strychnine weighed. Here occurs a manipulative difficulty which deserves to be mentioned. If the solution of strychnine in chloroform be directly evaporated to dryness upon the water-bath violent decrepitation will occur as the residue approaches dryness, resulting in the ejection of the greater part of the crystalline alkaloid from the dish. The chloroform should therefore be only partially expelled upon the water-bath, the remaining portion being spontaneously evaporated and the residue afterwards cautiously dried in a covered dish upon the water-bath, or the entire operation may be conducted in a flask. This behaviour is characteristic of pure or nearly pure strychnine, and is prevented by the presence of a small quantity of brucine, in which case the residue has a fused appearance. From the filtrate and washings the brucine is extracted by chloroform after the addition of excess of ammonium hydrate; in ordinary practice, however, either the brucine or strychnine may be estimated by difference. Table III. shows the results of a series of such experiments with different proportions of strychnine and brucine. It is to be noted that in these experiments the commercial crystalline alkaloids were employed, care being taken that the specimens selected were in definite crystals, but these alkaloids were not absolutely pure; the strychnine contained a mere trace of brucine and the brucine a similar trace of strychnine. It is further to be observed that in each case the strychnine and brucine have been directly determined.

As there is comparatively little difficulty in isolating strychnine and brucine from organic mixtures containing them, we have not considered it necessary to study the influence of organic matter upon the present results. When other alkaloids are present, the strychnine and brucine must be isolated before a separation is attempted. In the course of this investigation it has been frequently necessary to test a residue which was presumably brucine for the presence of strychnine and for this purpose we at first employed the well-known reaction with sulphuric acid and potassium dichromate or manganic oxide and found that for the detection of strychnine in presence of large quantities of brucine the test is useless, for the red colour produced by brucine under these conditions entirely masks the characteristic strychnine reaction.* We have made some experiments upon this point and generally upon the detection of strychnine in presence of brucine which will form the subject of a future communication. Taking advantage of the separation of strychnine and brucine effected by the method just described we have commenced experiments with the view of making the above process the basis of a method of preparing absolutely pure brucine; these experiments are still in progress. As might be anticipated the strychnine residues which were obtained gave evidence of traces of brucine when tested with nitric acid, the brucine also contained traces of strychnine. These traces were removed by reprecipitation. The results recorded in Table III. show that for all analytical purposes the separation of strychnine and brucine effected by the method above described may be considered as complete.

Our thanks are due to Professor Attfield, F.R.S., for having allowed this investigation to be carried on in the Laboratories of the Pharmaceutical Society and to the British Pharmaceutical Conference for having aided the work by a Research Fund grant.

* This has been previously noticed by Shenstone (*Pharm. Journ.*, [3], viii., 446), and since these experiments were made by Hanriot (*Comptes Rendus*, xcvii., 4).

Report upon the Pharmaceutical Preparations of Nux-Vomica.—I. On Tincture of Nux-Vomica.

BY WYNDHAM R. DUNSTAN,
Demonstrator of Chemistry,
AND F. W. SHORT,
Assistant-Demonstrator of Chemistry,
in the Laboratories of the Pharmaceutical Society.

Among the tinctures of the British Pharmacopœia tincture of nux-vomica stands pre-eminent in its union of potency and stability; the principal object of the present investigation was to test its uniformity. We have already shown (*Pharm. Journ.*, [3], xiii., 665, 1053) that the nux-vomica seeds of commerce vary considerably in the amount of alkaloid which they contain; it was, therefore, interesting in this connection to examine whether commercial specimens of the tincture similarly varied in strength. Twelve specimens of the tincture of nux-vomica of the British Pharmacopœia were obtained from the principal manufacturers in London, and these were subjected to analysis. In the first instance we made a number of experiments to obtain a simple and accurate process for the estimation of the total alkaloid in the tincture. Professor Dragendorff* has already proposed a method similar to the method proposed by him for the assay of the nux-vomica seeds. We have discussed this process elsewhere, and consider that the process for the assay of the tincture is open to the same objection there pointed out, namely, that it is unnecessarily long and intricate. When tincture of nux-vomica is evaporated a resinous mass remains, which will be found to be only partially dissolved by chloroform, the greater portion remaining insoluble. It is practically impossible to wholly extract the alkaloid from the mass by the use of chloroform alone. There are two ways in which the alkaloid may be isolated from it. (1) By treatment with ammonium hydrate, which dissolves the resinous mass and allows the alkaloid to be easily withdrawn by one or two agitations with chloroform, which solution is extracted by shaking with dilute sulphuric acid, and the alkaloid dissolved from this liquid after the addition of excess of ammonium hydrate by chloroform. The chloroform is then evaporated and the residue dried at 100° C. (2) By treatment with dilute sulphuric acid, which entirely dissolves the mass, and after the addition of ammonium hydrate the alkaloid can be extracted in the pure state by chloroform. These processes both yield finally the same result as will be seen from the following figures which represent the percentage of alkaloid found in a specimen of tincture analysed in both the above ways:—

Process 1	0·302 per cent.
Process 2	0·304 per cent.

The purity of the alkaloidal residues obtained by the above processes was tested by the ammonia-tannin method, which we have described in a previous paper (*Pharm. Journ.*, [3], xiii., 1054).

The following two experiments suffice to show that the residues obtained consisted of alkaloid, (α) percentage of alkaloid nominally found, (β) percentage after ammonia-tannin process:—

	α	β
1	0·103	0·093
2	0·159	0·153

The following table shows the results of the analysis of commercial tinctures of nux-vomica. In nearly all cases the second of the two above-mentioned processes was employed, 50 grams of the tincture being taken for analysis. In the residue of strychnine and brucine thus obtained the strychnine was separated and estimated by the method of precipitation by potassium ferrocyanide described by us in a previous communication; the brucine was estimated by difference. The percentages are in all cases by weight.

* 'Die chemische Werthbestimmung,' p. 71.

Analysis of Tinctures of Nux-Vomica.

No.	Specific gravity.	Percentage of total alkaloid.	Percentage of strychnine.	Percentage of brucine.
1	0·8426	0·224	0·077	0·147
2	0·8409	0·262	0·097	0·165
3	0·8438	0·208	0·068	0·140
4	0·8392	0·124	0·049	0·075
5	0·8450	0·360	0·121	0·239
6	0·8378	0·211	0·084	0·127
7	0·8377	0·136	0·046	0·090
8	0·8552	0·181	0·066	0·115
9	0·8398	0·196	0·077	0·119
10	0·8413	0·189	0·087	0·102
11	0·8407	0·168	0·060	0·108
12	0·8436	0·263	0·131	0·132

It will be seen from these results that the tinctures of nux-vomica now in commerce vary to a very considerable extent in alkaloidal strength. The strongest tincture (No. 5) containing nearly three times as much total alkaloid as the weakest (No. 4). It will be at once conceded that the important feature in a typical tincture of nux-vomica is or should be uniformity in alkaloidal strength; the other constituents though doubtless valuable are of secondary importance. In view of the above facts it seems desirable (1) that a standard uniformity should be officially recognized; (2) that the pharmacist should be able to prepare and guarantee the tincture of standard strength. This accomplished, the pharmacist, having determined the amount of total alkaloid contained in the seeds from which the tincture is to be prepared, employs a sufficient quantity to produce by a process of uniform exhaustion the standard tincture.

The work connected with this communication, which forms part of a general investigation of the pharmaceutical preparations of nux-vomica, has been carried on in the laboratories of the Pharmaceutical Society by the kind permission of Professor Attfield, F.R.S.

The President, in proposing a vote of thanks to the authors of these papers, remarked that in the first paper they had made a most distinct advance in the knowledge of the chemistry of strychnine and brucine, and had given what seemed a thoroughly trustworthy method of determining the amount of strychnine. In dealing with the difficult subject of nux-vomica they first devised an ingenious apparatus for extracting the whole of the active principles. They then devised a method for separating and quantitatively estimating each of the alkaloids, and they were now apparently engaged in adapting their physical and chemical discoveries to the practical assay of the preparations of nux vomica. In all this they had done valuable service.

A vote of thanks to the authors was passed.

Mr. Naylor remarked that Mr. Siebold had already studied this subject pharmaceutically, and communicated his results to a former Conference. He then threw out the suggestion that the extract of nux-vomica should be employed in the preparation of the tincture, and it seemed to him that this suggestion was well worthy of consideration. They should be slow to adopt any method which would entail either on the wholesale house or the pharmacist the duty of assaying the nux-vomica, especially considering the great difficulty there would be in obtaining nux-vomica which would come up to the standard given by Messrs. Dunstan and Short. As far as he could understand, there was no standard fixed for the proportion the strychnine should bear to the brucine. He believed this was the first time the two alkaloids had been separated in a condition of purity, and, therefore, their physiological action had not yet been definitely ascertained. The weakness of nux vomica tincture which had been mentioned was probably due to one or both of two causes: first, pharmacists as a rule had not the means of sufficiently dividing the nux-vomica so as to completely exhaust it; and, secondly, if it were heated too much, the alkaloids would be destroyed.

Mr. BENGER said in the paper alluded to by Mr. Naylor, which was read by Mr. Siebold at the Glasgow meeting, it was stated that various specimens of tincture of nux-vomica had been analysed, and as the result, it had been found that in a good sample about nine parts per thousand of tincture consisted of dry extract. It was interesting to find that the results obtained by Messrs. Dunstan and Short were confirmatory of Mr. Siebold's conclusions in another respect, although arrived at by quite a different method. Mr. Siebold examined ten specimens of tincture, and found that the strongest was about three or four times the strength of the weakest, judging simply by the bitterness produced by the addition of it to a definite quantity of water, and by the amount of opalescence produced. He did not know that there was any conclusive evidence that the amount of strychnine and brucine in nux-vomica was to be taken as an absolute indication of the medicinal value. If so, it would be better at once to use liquor strychniæ or liquor strychniæ cum brucia.

Mr. HOLMES remarked that one important point which had been brought out in the paper was the great variation in the strength of the tincture of nux-vomica. He remembered hearing Professor Bentley say that he had been nearly poisoned on one occasion by taking a much stronger tincture than he supposed he was taking. Messrs. Dunstan and Short had also shown that the seeds of nux-vomica met with in commerce varied very much in strength. There were two or three varieties known, the Bombay being much stronger than the others. If this were the case and the seeds were mixed, it seemed to him that Mr. Benger's suggestion to use the liquor strychniæ was a very valuable one, for it would be almost impossible for a chemist to secure one particular kind of seed, and thus it would be very difficult to ensure a tincture of uniform strength.

Mr. TANNER said, that in his experience Mr. Siebold's suggestion for the preparation of tincture from the extract had not proved very satisfactory. A large quantity of spirit was necessary to dissolve the active principles from the nux vomica, and in the preparation of the extract evaporation of the menstruum was necessary. When the extract was redissolved to form the tincture, it did not entirely dissolve, for there was a proportion of fixed oil found in the extract; and further, in the tincture made by that method, after being kept some length of time, there was a brown deposit formed on the sides and bottom of the vessel, arising probably from some changed resinous substance.

Mr. CONROY asked if he correctly gathered that the strongest samples of tincture of nux-vomica were those of the highest specific gravity.

Mr. PLOWMAN said it was so broadly—not exactly.

Mr. CONROY said, that seemed to suggest that the rectified spirit of the Pharmacopœia was not a suitable menstruum to exhaust the nux-vomica with, and that a spirit containing more water would be preferable.

Mr. A. C. ABRAHAM observed, that formerly a weaker spirit was used, and was now generally used by foreign pharmacists. The Dublin Pharmacopœia ordered proof spirit; the French Codex was alcohol of 80° = sp. gr. 0·864; the Pharm. Germanica spiritus dilutus, sp. gr. 0·892. There was no doubt, he thought, that it dissolved the active principles more readily than rectified spirit.

Mr. JACKSON said that the use of a weaker spirit had been recommended at a former meeting of the Conference by Mr. Prescott, who used a spirit of sp. gr. ·970, and found it much better than that of the official strength. In a former communication on the subject of strychnia, either to the Conference or to the Chemical Society, Mr. Shenstone had given a process for separating strychnia from brucia; but from the remarks now made it would seem as if Messrs. Dunstan and Short had now, for the first time, introduced a process for the preparation of pure alkaloids of strychnia and brucia. He should be glad to know if Mr. Shenstone's paper had been overlooked. There had also appeared in the *Pharmaceutical Journal* a notice of the Exhibition at Vienna, in which it was stated that samples of pure brucia were exhibited. It would be very interesting to know by what process they were prepared.

Mr. WHITLEY WILLIAMS said, if he recollected rightly, Mr. Shenstone came to the conclusion that no process of precipitation succeeded in separating the strychnine from the brucine, and he was surprised to hear that this was a precipitation process. Mr. Shenstone recorded a result, in which he was corroborated by the authors of this paper, that strychnine precipitated from a ferrocyanide solution invariably gave a vivid brucine reaction. If that were so, he did not see how it was possible to separate strychnine from brucine by that process. It was probable that brucine was taken down not altogether chemically by a want of solubility of it in the ferrocyanide, but was mixed the strychnia in some physical manner. For instance, Meyer's solution was alluded to as a precipitant for the estimation of the alkaloids, and probably the proportion of pure alkaloid in a pure solution could be estimated quite exactly in that way; but if the alkaloid were mixed with some other substances and colouring matters, the precipitate invariably carried down with it a number of other things, and he believed that if Messrs. Dunstan and Short had examined minutely this precipitate of ferrocyanide of strychnine, they would have found that it still contained brucine.

Mr. REYNOLDS (Leeds) begged to congratulate the President as chief of the school which had sent this valuable contribution to pharmaceutical research. There was no more healthy indication of the condition of a school than such bye-products. The original intention might be the production of successful students; but just as in a gas works, the bye-products were sometimes more valuable than the gas, so these researches were most valuable, and it was unfortunate that there were not more schools of pharmacy in the country from which similar results might arise. He trusted that the acceptance of pharmacy as a subject of study at Owens College would lead to a multiplication of such contributions in future.

Mr. PLOWMAN said he could not attempt to reply to any criticisms on the papers, but in reply to Mr. Williams he might repeat a sentence of the paper which said—"as might be anticipated the strychnine residues gave evidence of traces of brucine when tested with nitric acid; the brucine also contained traces of strychnine. These traces were removed by reprecipitation."

The PRESIDENT said he could not allow the discussion to close without thanking Mr. Reynolds for his kindly notice of the work done by the gentlemen who had been students in the school of pharmacy of which he had the honour of being a professor; but he must not give too much credit to him or his colleagues for this work. The Council of the Society had always supported the endeavours of the students, not only to study the known, but to dip a little way into the unknown; and had encouraged the Pharmaceutical Students' Association which had similar objects to one which existed many years ago when he was a pupil there; and it had done good work in promoting original research. It was very gratifying to him to find men who had been members of the Students' Association, and some of whom had been officers, coming forward and doing work which commended itself to the consideration of the Conference.

(To be continued.)

NATIONAL ASSOCIATION FOR THE PROMOTION OF SOCIAL SCIENCE.

In the "Repression of Crime Section" of the above Association, which has been holding a meeting in Huddersfield, there were read on Tuesday last two papers on the question "Can the Law regulating the Sale of Poisons be amended so as more effectually to prevent their Employment for Criminal Purposes;" one by C. Meymott Tidy, M.B., F.C.S., Professor of Chemistry and of Forensic Medicine at the London Hospital, and the other by Mr. G. Latham Browne. The former of these is now printed; the latter, together with the discussion which followed the reading of the papers will be published in the next number of this Journal.

Can the Law Regulating the Sale of Poisons be amended so as more effectually to prevent their Employment for Criminal Purposes.

BY C. MEYMOTT TIDY, M.B., F.C.S.

I.—The Present State of Legislation Regulating the Sale of Poisons.

An Act entitled "An Act to regulate the sale of poisons, and alter and amend the Pharmacy Act, 1852," came into operation on January 1, 1869. Ireland is exempted from its operations.

So far as we are concerned at the present moment four points call for separate consideration. 1st. The articles deemed poisons under the Act. 2ndly. The persons permitted to sell the articles so designated. 3rdly. The precautions required to be taken in effecting the sale of such articles; and 4thly. Certain exceptional circumstances under which poisons may be sold by others than those named, and under conditions not regulated by the Act.

1. *The Articles deemed Poisons within the meaning of the Act of* 1868.

In Schedule A. of the Act the various articles to be deemed poisons are scheduled. They are divided, for reasons I shall discuss shortly, into two parts, called respectively—Part I. and Part II., and are as follows:—

Part I.

Arsenic and its preparations.
Prussic acid.
Cyanides of potassium and all metallic cyanides.
Strychnine and all poisonous vegetable alkaloids and their salts.
Aconite and its preparations.
Emetic tartar.
Corrosive sublimate.
Cantharides.
Savin and its oil.
Ergot of rye and its preparations.

Part II.

Oxalic acid.
Chloroform.
Belladonna and its preparations.
Essential oil of almonds, unless deprived of its prussic acid.
Opium and all preparations of opium or of poppies.

By Section 2, permission was granted to the Council of the Pharmaceutical Society of Great Britain to suggest additions to this list. Such additions are to be submitted to the Privy Council. Upon approval they are to be advertised in the *London Gazette*, and, after the expiry of one month, are to be deemed poisons within the meaning of the Act.

Of this power the Council of the Pharmaceutical Society of Great Britain has on more than one occasion availed itself, and the articles now designated poisons are scheduled as follows:—

Part I.

Arsenic and its preparations.
Aconite and its preparations.
Alkaloids—all poisonous vegetable alkaloids and their salts.
Atropine and its preparations.
Cantharides.
Corrosive sublimate.
Cyanide of potassium, and all metallic cyanides and their preparations.
Emetic tartar.
Ergot of rye and its preparations.
Prussic acid and its preparations.
Savin and its oil.
Strychnine and its preparations.
Vermin killers—of preparations of poisons, the preparations of which are in Part I. of this schedule.

Part II.

Almonds, essential oil of (unless deprived of prussic acid).
Belladonna and its preparations.
Cantharides, tincture and all vesicating liquid preparations of.
Chloroform.
Chloral hydrate and its preparations.
Corrosive sublimate, preparations of.
Morphia, preparations of.
Opium and its preparations, and preparation of poppies.
Oxalic acid.
Precipitate red (red oxide of mercury).
Precipitate white (ammoniated mercury).
Vermin killers (see Part I.)—compounds containing poisons prepared for the destruction of vermin, if not subject to the provisions of Part I.

A special Act, called "An Act to regulate the sale of poisons in Ireland," received the Royal assent on July 14, 1870 (33 and 34 Vict. cap. 26). The articles deemed poisons under this Act, as in the Pharmacy Act of 1868, are scheduled in two parts, and in all respects resemble those catalogued in the Pharmacy Act of 1868. In Ireland the King and Queen's College of Physicians is the body appointed to suggest such additions to the Act as may be desirable. Practically, therefore, it may be said that there is complete uniformity in the law governing the sale of poisons within the United Kingdom.

Secondly.—We have to consider the Persons under the Act permitted to sell the Articles deemed Poisons.

The sale of poisons or the dispensing and compounding them is limited under the Pharmacy Act: (1) To registered pharmaceutical chemists. (2) To those who before the passing of the Act of 1868 carried on in Great Britain the business of "chemists and druggists" in the keeping of open shop for the compounding of the prescriptions of duly qualified medical practitioners (Section 3), and who have been duly registered and (if registered since December 31, 1868) paid their fee; and (3) Those assistants who prior to the Act were of full age (21), and had been engaged for three years previously in the dispensing and compounding prescriptions as assistants to pharmaceutical chemists or to chemists and druggists within the meaning of the Act, and who present themselves to the Pharmaceutical Society to undergo a certain modified form of examination (Section 4)—their status being duly attested and their names registered.

By Section 17 it is enacted that the seller of a poison is the person on whose behalf the sale is made.

In Section 15 penalties are provided to protect the various titles of chemist, druggist, pharmacist, etc.

Thirdly.—We have to consider the Precautions required to be taken by the Persons permitted to sell the Articles deemed Poisons under the Act.

I have already noted that the articles deemed poisons are scheduled under two parts.

It is enacted that any vessel, wrapper or cover in which any poison enumerated in either part of the Act so scheduled is contained, must be distinctly labelled with the name of the article—the word "poison"—and the name and address of the seller (Section 17).

But in the case of those poisons scheduled under Part I. it is further necessary that the purchaser shall either be known to the seller or be introduced to the seller by some person known to him. Further, at every sale of any such article, the seller shall, before delivery, make, or cause to be made, an entry in a book to be kept for that purpose of—

(1) The date of the sale.
(2) The name and address of the purchaser.
(3) The name and quantity of the article sold.
(4) The purpose for which the poison is stated to be required. To this shall be affixed the signature of the purchaser, and of the person, if any, who introduced him.

The sale of arsenic and of its preparations was dealt with in a special Act (14 Vict. cap. 13), entitled "An Act to regulate the Sale of Arsenic." By the term arsenic is included arsenious acid and the arsenites—arsenic acid and the arsenates, and all other colourless poisonous preparations of arsenic. In addition to the precautions required under the Act of 1868 in the sale of the poisons named in Part I. of Schedule A., and which includes arsenic, the following further precautions detailed in the unrepealed Act of 1851 are demanded of the seller:—

(1) That the arsenic shall be mixed with soot or indigo in the proportion of 1 ounce of soot or ½ ounce of indigo to every pound of arsenic. But if the purchaser represent that such admixture would render the arsenic unfit for the purpose for which he required it (in other words, that he does not need it for agricultural purposes), then it may be sold without such admixture, but the quantity so sold at any one time must not be less than 10 pounds (Section 3).

(2) That if the purchaser be unknown to the seller, he must be accompanied by a person known both to the seller and to the purchaser, the sale being effected in the presence of the third person, who shall sign his name and residence in the poison book (Section 2).

(3) That the person to whom the arsenic is sold must be of mature age (Section 2).

(4) That in addition to the details required under the Act of 1868, the purchaser must also state his occupation and condition (Section 1).

The penalty for offending against this Act is £20 (Section 4).

Fourthly.—The exceptional Circumstances under which Poisons may be Sold by Persons other than Pharmaceutical Chemists, and without the usual Conditions Restricting the Sale of Poisons.

I have already noted that in the case of arsenic, should the purchaser represent that the object for which he requires the arsenic is not agricultural, and that the admixture of soot or indigo would render it unfit for his purpose, he may then be served with the arsenic unmixed with any other ingredients, but that the quantity so purchased at any one time must not be less than 10 pounds (14 Vict. cap. 13, sec. 3).

Further, none of the regulations to which I have referred apply to any article constituting a part of the prescription of a legally qualified medical practitioner, dispensed by a registered chemist and druggist (14 Vict. cap. 13, sec. 5); but at the same time it is enacted that should such prescription contain any of the articles scheduled under the 1868 Act as poisons, the chemist must then enter the prescription in a book (called a prescription book) kept for that purpose, with the name of the person to whom the medicine is sold or delivered, whilst on the bottle or wrapper containing such medicine the name and address of the seller is to be stated.

It is to be noted that by Section 17 of the 1868 Act, repeated in Section 3 of the Amendment Act of 1869, it is required (at least so I read it) that the legally qualified practitioner shall in cases where articles deemed poisons under the Act of 1868 are employed as ingredients in his medicines, place on the bottle his name and address, and also enter the prescription with the person to whom such medicine is sold or delivered in a book kept for the purpose.

Again, by Section 16, the making or dealing in patent medicines (such, *e.g.*, as chlorodyne) is excepted from the provisions regulating the sale of poisons.

Further, wholesale dealers are not included within the provisions of the Act when supplying poisons to the retailer (14 Vict. cap. 13, sec. 5) upon order in writing, in the ordinary and legitimate course of wholesale dealing, nor do the precautionary provisions of Section 17 apply to articles exported from Great Britain.

On the death of a pharmaceutical chemist the business may be continued by an executor or trustee, provided it be *bonâ fide* conducted by a duly qualified assistant.

Money penalties are in all cases named, as well for using false titles, as for any infringement of the regulations relating to the sale of poisons.

The word "poison," I would remark, is not to be found in either of the Acts relating to the Adulteration of Food of 1875 or of 1879, but the admixture for any purpose of an article "injurious to health" with an article of food (Section 3) or with a drug (Section 4) with guilty knowledge (Section 5), is prohibited under a fine of £50 for the first offence, and for a second offence (which is then a misdemeanour) of imprisonment, for a period not exceeding six months, with hard labour. It is not, however, regarded as an offence (that is, so far merely as prejudice of the purchaser is concerned) if the food or drug be a proprietary medicine, or is the subject of a patent in force and supplied in the state required by the specification of the patent (Section 6).

II.—THE PRECISE OBJECTS FOR WHICH LEGISLATION IS NEEDED.

Having thus far attempted to place before you the existing laws regulating the sale of poisons, it becomes important to consider the unlawful uses to which poisons may be applied, and to prevent which such legislation becomes necessary. We shall then be in a position to consider how far the laws at present existing are sufficient to prevent or to throw difficulties in the way of the various offences for which poisons may be employed. To this point I shall very briefly direct your attention.

In "An Act to consolidate and amend the statute laws of England and Ireland relating to malicious injuries to property" (24 and 25 Vict. cap. 97, sec. 32) it is enacted, "Whosoever shall . . put any lime or other noxious material in any such pond or water" [*i.e.* water which shall be private property, or in which there shall be any private right of fishery], "with intent thereby to destroy any of the fish that may there be or that may thereafter be put therein . . . shall be guilty of a misdemeanour, etc." This section is, by the 36 and 37 Vict. cap. 71, sec. 13, extended to salmon rivers.

It is, however, worth remarking that the word poison occurs in the 5th section of the Act entitled "An Act to amend the laws relating to fisheries of salmon in England" (24 and 25 Vict. cap. 109). "Every person who causes or knowingly permits to flow, or puts or knowingly permits to be put, into any waters [defined in the Act] containing salmon [defined in the Act], or into any tributaries thereof, any liquid or solid matter to such an extent as to cause the waters to poison or kill fish shall incur the following penalties, etc." The application of the section, however, is limited when such Act is done in the exercise of a legal right, the best practicable means having been taken, within reasonable cost, to render the poisonous material so introduced harmless. By Section 6, the defendant may, if the justices decide against him as to what constitute the best practicable means and reasonable cost, have the case decided by a jury.

The 39th Vict. cap. 13, is "An Act to prevent the administration of poisonous drugs to horses and other animals," and is cited as "The Drugging of Animals Act, 1876." It provides by Section 1 that "if any person wilfully and unlawfully administers to or causes to be administered to or taken by any horse, cattle or domestic animal any poisonous or injurious drug or substance, he shall . . . be liable, etc."

See also 24 and 25 Vict. cap. 97, secs. 40, 41.

In the "Poisoned Grain Prohibition Act of 1863" (26 and 27 Vict. cap. 113), Section 2, provides "Every person who shall offer or expose for sale or sell any grain, seed or meal which has been so steeped or dipped in poison, or with which any poison or any ingredient or preparation has been so mixed, as thereby to render the same poisonous, and calculated to destroy life, shall in either case for every such offence, upon summary conviction as hereinafter provided, forfeit any sum not exceeding £10.

Section 3 relates in similar language, and with a similar punishment on conviction, to cases where the prisoner has "knowingly and wilfully sown, cast, set, lay, put or placed, or caused to be sown, cast, set, laid, put or placed into, in or upon any ground or other exposed place or situation, any such grain, seed or meal," etc.

Section 4, except "any solution or infusion, or any material or ingredient used for dressing, protecting, or preparing any grain or seed for *bonâ fide* use in agriculture only, or the sowing of such last-mentioned grain or seed so prepared."

This Act was by the 27th and 28th Vict. cap. 115 (known as the "Poisoned Flesh Prohibition Act, 1874") extended. Section 2 of this Act provides that "Every person who shall knowingly and wilfully set, lay, put or place, or cause to be set, laid, put or placed, any flesh or meat which has been mixed with or steeped in, or impregnated with poison or any poisonous ingredient, so as to render such flesh or meat poisonous, and calculated to destroy life, shall upon a summary conviction forfeit any sum not exceeding £10. It is, however, permissible under this section for owners or occupiers of land in Ireland, "to lay or cause to be laid any poisonous matter as hereinbefore described, after a notice has been posted in a conspicuous place, and notice in writing has been given to the nearest constabulary station."

By Section 3 exemption is made to the occupier of a house or the owner of a rick or stack of wheat, etc., using poisoned preparations for the destruction of vermin, either in his house or "in any enclosed garden attached to such dwelling house or other building, or in the drains connected with such dwelling house, provided that such drains are so protected with gratings or otherwise as to prevent any dog from entering the same, or within such rick or stack any poison or poisonous ingredient or preparation for the destruction of rats, mice or other small vermin."

Administration of Poisons to Human Beings.

As regards any indictment for murder or manslaughter, or even as an accessory, it is not necessary to state the means by which the death of the deceased was caused, but in the case of murder, "that the defendant did feloniously, wilfully, and of his malice aforethought kill and murder the deceased, and in an indictment for manslaughter that "the defendant did feloniously kill and slay the deceased" (Section 6).

Attempted poisoning with intent to murder is dealt with in the 24th and 25th Vict. cap. 100, sec. 11, in these words, "Whosoever shall administer to, or cause to be administered to, or to be taken by any person any poison or other destructive thing, or shall by any means whatsoever wound or cause any grievous bodily harm to any person, with intent in any of the cases aforesaid to commit murder, shall be guilty of felony," etc. (See also Section 18).

Similarly, by Section 14 the administration or attempting "to cause to be administered to, or taken by any person any poison or other destructive thing with intent to commit murder," is, "whether any injury be effected or not," a felony punishable with penal servitude.

By Section 22 it is enacted that "Whoever shall unlawfully apply or administer to, or cause to be taken by or attempt to apply or administer to, or attempt to cause to be administered to or be taken by any person, any chloroform, laudanum or other stupefying or overpowering drug, matter, or thing, with intent in any of such cases thereby to enable himself or any other person to commit, or with intent in any of such cases thereby to assist any other person in committing any indictable offence, shall be guilty of felony, etc."

The 21st section is in all respects similar, but applies to "Whosoever shall by any means whatsoever attempt to choke, suffocate, or strangle any other person, or attempt to render any other person insensible, unconscious, or incapable of resistance," with intent to commit, or to assist others in committing any indictable offence.

Some difficulties having arisen relating to the unlawful administration of poison in cases where the intent was not to commit murder, an Act was passed in 1860, the clauses of which were included in the Act of 1861 (Clauses 23, 24, and 25).

By Section 23 it is enacted that "whosoever shall unlawfully and maliciously administer to, or cause to be administered to, or taken by any other person, any poison or other destructive or noxious thing, so as thereby to endanger the life of such person, or so as thereby to inflict upon such person any grievous bodily harm, shall be guilty of felony, etc."

By Section 24 it is enacted that "whosoever shall unlawfully and maliciously administer to, or cause to be administered to, or taken by any other person, any poison or other destructive or noxious thing with intent to injure, grieve or annoy such person, shall be guilty of a misdemeanour, and shall, etc."

Section 29 treats as a felony, whether or not any bodily injury result, causing the internal administration by any person "of any explosive substance, or any other dangerous or noxious thing with intent to bruise, maim, disfigure, or disable any person, or to do some grievous bodily harm." The section also deals with causing gunpowder to explode, or the sending to any person an explosive substance or other dangerous or noxious thing, or throwing corrosive fluid on a person. By Section 64 the mere making of explosive substances or any dangerous or noxious thing with intent by means thereof of committing a felony, is regarded as a misdemeanour.

Attempt to procure Abortion.

This is dealt with by the 58th and 59th sections.

By Section 58 it is enacted, "Every woman, being with child, who, with intent to procure her own miscarriage, shall unlawfully administer to herself any poison or other noxious thing, or shall unlawfully use any instrument or other means whatsoever with a like intent, and whosoever, with intent to procure the miscarriage of any woman, whether she be or be not with child, shall unlawfully administer to her, or cause to be taken by her, any poison or other noxious thing, or shall unlawfully use any instrument or other means whatsoever, with the like intent, shall be guilty of felony, etc."

By Section 59 it is enacted that, "Whosoever shall unlawfully supply or procure any poison or other noxious thing, or any instrument or thing whatsoever, knowing that the same is intended to be unlawfully used or employed with intent to procure the miscarriage of any woman, whether she be or be not with child, shall be be guilty of a misdemeanour, etc."

III.—HOW FAR ARE THE OBJECTS OF THE LEGISLATURE TO PREVENT THE UNLAWFUL USE OF POISONS SERVED BY THE PRESENT STATE OF THE LAW REGULATING THEIR SALE?

And here there at once arises an important and (it must be confessed) difficult question. What is a poison? The law nowhere defines it. Further, the subject (as you will have noticed) is complicated by the use of a variety of words and phrases, viz.:—

"Noxious thing," 24 and 25 Vict., secs. 23, 24, 29, 58, 59.

"Noxious material," 24 and 25 Vict., cap. 97, sec. 32.

"Destructive thing," 24 and 25 Vict., cap. 100, secs. 11, 14, 23, 24.

"Stupefying drug, matter, or thing," 24 and 25 Vict. cap. 100, sec. 22.

"Overpowering drug, matter, or thing," 24 and 25 Vict., cap. 100, sec. 22.

"Poison," 24 and 25 Vict., cap. 109, sec. 5; 26 and 27 Vict., cap. 113, secs. 2 and 3; 27 and 28 Vict., cap. 115, sec. 2; 24 and 25 Vict., cap. 100, secs. 11, 14, 23, 24, 25, 58, 59."

"Poisonous drug," 39 Vict., cap. 13, sec. 1.

"Injurious drug or substance," 39 Vict., cap. 13, sec. 1.

"Poisonous ingredient," 27 and 28 Vict., cap. 115, s. 2.

"Poisonous matter," 27 and 28 Vict., cap. 115, sec. 2.

"Poisonous preparation," 27 and 28 Vict., cap. 115, s. 3.

In the Adulteration Act none of these words are used, a poisonous body being included under the phrase an article injurious to health.

It may of course be urged that many of these terms imply the same thing. This may or may not be so, but it is curious how the terms are intermixed in different Acts of Parliament. To add to the difficulty, it is common to find in indictments for murder by poisoning, the phrase, "Deadly poison," used as though the word poison was not sufficiently expressive nor explicit.

The popular definition of a poison is, "a drug that kills rapidly when administered in small quantity;" but then many poisons do not kill in what is popularly termed a small quantity, whilst many most deadly poisons do not destroy life rapidly. Orfila defined a poison as "a substance which, taken internally or applied to the body of man or animal, destroys health or annihilates life by acting in virtue of its nature"—a definition, we must admit, of a somewhat vague nature.

I venture to contribute a definition of a poison as "anything which, otherwise than by the agency of heat or electricity, is capable of destroying life either by chemical action on the tissues of the living body, or by physiological action from absorption into the living system." There are two essentials only to my mind necessary to constitute a body a poison:—

1. That the thing shall be capable of destroying life.
2. That in doing so, its *modus operandi* should be chemical or physiological.

The substance to be a poison must be capable of destroying life. Thus the term "*deadly poison*" is, to quote Mr. Justice Erle's words, mere legal surplusage. If a thing is a poison, it is deadly. If it be not deadly, it is not a poison.

But still the question arises, are we altogether to ignore the element of dose? The question is important in discussing the question of the regulations necessary to guard the sale of poisons. To be a poison or a noxious thing, the administration of which constitutes a felony, must the substance be noxious in itself, or noxious only when administered in excess? This is no fanciful difficulty. It occurred in the case of the Queen *v.* Hennah, tried at the Cornish assizes, where the prisoner was charged with the administration of cantharides, although in quantity so minute as to be innocent. The Lord Chief Justice Cockburn and Mr. Justice Hawkins decided that to be a noxious thing the drug must be noxious in itself, and not merely noxious when an excess had been administered. Again, in the case of R. *v.* Percy (9 Cox's Criminal Cases), it was ruled that any substance which caused sickness only was not a noxious thing, whilst in a third case Chief Baron Pollock said: "We are all of opinion that the thing must be noxious in itself."

In the case of R. *v.* Cramp, a man was tried for having unlawfully administered to a woman a noxious thing (viz., ½ ounce of oil of juniper), for the purpose of procuring abortion. Vomiting and purging set in, and ultimately she miscarried. The jury found the prisoner guilty of administering a noxious thing. The question whether the oil of juniper was a noxious thing within the meaning of the Act was referred to the Court for Crown Cases Reserved. Lord Chief Justice Coleridge (with him Mr. Justices Denman, Field and Stephen), in giving judgment said: "The question is whether the prisoner was guilty of administering a poison or other noxious thing with intent to produce miscarriage. The intent was found. Was the substance administered a noxious thing? It was oil of juniper, and administered in such quantity as was the case it was certainly noxious. But it was said the substance must be some kind of poison, and probably it must be so. But what is a poison? Something destructive or injurious to human life. There is hardly any active medicine which in large quantities may not be so, and on the other hand, there is hardly any poison which may not in certain quantities and in given circumstances be salutary. The reasonable construction therefore is, that in each case it is a question for the jury whether the substance administered as it was, and in the circumstances in which it was administered, was a noxious thing. In the present case all the ingredients of the offence charged were made out. Therefore, neither principle nor authority preclude us from holding what is certainly good sense, that if a person administer with intent to produce miscarriage something which, as administered, is noxious, he administers a noxious thing. The conviction, therefore, must be affirmed."

By a *drug* or *medicine* we ordinarily understand "a substance administered with the object of restoring the normal functions disturbed by disease, or else of curing lesions which may have attacked the various tissues and organs. By a *poison* we understand a chemical substance which, introduced into the animal organism, may produce lesions or serious functional disorders threatening life. Admitting this distinction, it is equally certain that there is no boundary line—at any rate no well-defined boundary line—separating poisons from drugs and medicines. Poisons do not constitute a natural group capable of exact definition. The poison may be a medicine, and the medicine a poison, according to circumstances. After full consideration it appears to me that a poison in the hands of a poisoner should be regarded in the same light as a revolver in the hands of a burglar, and that poisoning should be deemed a form of violent death, different only in form from strangulation and the like."

I have occupied you some time in discussing the meaning of the word poison and the improper uses to which poisons may be placed, and I now ask you to return to our starting point, viz., their sale, and see how far present legislation is efficient or sufficient.

And here one fact is manifest. We can never, by any possible legislation, prevent poisons from getting into the hands of those who have made up their minds to get them and to use them improperly. The best we can do is to throw every difficulty in the way of obtaining them, and to impose such conditions that, in the event of an improper use, we have at any rate some chance of discovering the criminal. Perfect efficiency is impossible. Nor do I think that in this matter, knowing the absolute impossibility of perfect legislation, that we should attempt to over-legislate. For, on the one hand, over-legislation would draw an amount of attention to a subject which, in my judgment (and I speak with not a little experience), the less known by those who have the evil eye and the evil mind the better; whilst to others—to the educated and well-informed—other difficulties may arise. Things may come to this, that we shall be afraid to live for fear we die.

And now for the Act regulating the sale of poisons. The word poison, I have said, is not defined, but the various bodies to be deemed poisons within the meaning of the Act are scheduled.

I object *in toto* to this scheduling. It serves to draw attention to a number of drugs that had far better not be specified. The Schedule is a most remarkable document. It is, I said, divided into two parts. When the poisons enumerated in Part I. are sold, the buyer must be known to the seller, or be introduced to the seller by some person known to him, whilst certain detailed entries in the poison book are required. In the case of poisons under

Part II., such precautions are deemed unnecessary. Let me give you an example. If I go to a chemist and ask for some emetic tartar (a poison undoubtedly, but one that, owing to its emetic properties, as often fails to kill as not) either I must be known to the chemist, or I must take an introduction to him from someone that he knows. In such case, moreover, he enters in his poison book my name and address, or the name and address I choose to give him, the name and quantity of the article sold, and the purpose for which I choose to tell him I require it—all of which details must be duly attested. But if I desire to purchase some opium no such precautions are needed.

Again, if I ask a chemist for some corrosive sublimate or morphia, or for some cantharides, I must be known or duly introduced, and due entries of the sale, etc., recorded. If I ask for a preparation of corrosive sublimate or for *a preparation of morphia* (and a preparation may contain any percentage of the active agent mixed with ever so small a proportion of an absolutely inert one), or for some tincture of cantharides, I need neither be known nor introduced, nor need any written records against me be preserved.

Again, all poisonous vegetable alkaloids and their salts are (very rightly) included in Part I. But the force of this is again lessened by a few vegetable alkaloids being specially named (viz., aconite, atropine, strychnine), all of which poisons are surely included in the phrase poisonous vegetable alkaloids. It may be argued, there is no harm in such repetition. But there is this harm, that there are certain bodies not specially named, and the naming some and not others is undoubtedly an evil.

The exact meaning of the word preparation is nowhere defined. Anything may be held to be a preparation of a substance. "Preparations of prussic acid" are, for example, specially named, a phrase to my mind far from explicit. A salt of a substance is often termed in ordinary language a preparation of that substance. Thus sulphate of morphia might be and often is termed a preparation of morphia. Atropine and its preparations are included in Part I. Belladonna and its preparations in Part II. Morphia would be included amongst the poisonous vegetable alkaloids in Part I. (although why it should not be specially named I do not understand, seeing that strychnine and atropine are); the buyer of these, therefore, must be personally known or introduced. But in the purchase of preparations of morphia no such precautionary measures are demanded.

But the schedule errs by sins of omission. I shall not be accused of egotism if I claim some experience for many years, as the pupil, assistant and colleague of Henry Letheby, and since his death on my own account, with the subject of poisons and poisoning. Recalling a personal experience then of a good many years, it is remarkable that the two poisons which in my experience have been the cause of many accidental deaths, and have also been used more frequently suicidally than any other, and two poisons, moreover, of a most deadly nature, are not included in the schedule at all. I refer to carbolic acid and phosphorus.

You ask, what remedy have you to suggest? I answer, define a poison, accurately and scientifically, and omit the schedule. As a preventive measure it is unadvisable (I am convinced) to publish a list of poisons. Further, if such a list be prepared, no matter how carefully, it is sure to offer abundant material for legal quibbles.

What has been the result of all this scheduling and this Part I. and Part II. legislation? That the Act at the present time is not carried out in its entirety, and I almost venture to say is an impossible Act to be obeyed. Strictly it does not seem to have been carried out in the purchase of the aconitine used with such fatal effect by Lamson. The fact is, anybody (with a little trouble, perhaps, but very little) can get almost any poison they want, and in almost any quantity. Fancy a woman being able to purchase five pints of laudanum at one shop. I tell of that I can vouch ...

Over legislation has in this case proved under-legislation. Simplify, I say, the whole thing. Define a poison, and omit all schedule of names. Require that the sale shall be the act of a pharmaceutical chemist only, and that the pharmacist keep a record of the sale, the person's name and address, and the object as stated for which the poison was said to be required. Enough records should be demanded to throw difficulties in the way of persons procuring poisons for improper purposes, but not too many, lest too many may mean in the long run none at all. Further, it may fairly be taken for granted that with the present race of pharmacists some little judgment will be used in the sale of poisonous preparations, and for which judgment no Act of Parliament can provide. It would be absurd to require poison regulations to apply to such things as an opium plaster or a Dover's powder, or medicinal doses of pulv. cretæ c. opio or paregoric—all of which, strictly speaking, are preparations of opium. Any legislation is sure to fail unless you credit the pharmacist with a certain amount of common sense in his commercial proceedings.

Taking, then, the whole of the facts into consideration, together with the various decisions, I would venture to suggest the desirability in future legislation of using the word "poison" only in the place of the various phrases I have referred to, the chief uses of which are as battle grounds for the arguments of counsel. I would further suggest an interpretation clause defining the word poison somewhat in the terms I have proposed. In the case of the 24th and 25th Vict., cap. 100, and some other Acts, the phrase "poison or other destructive thing" will be required. I have stated that a substance to be a poison must act chemically or physiologically on the body—that is, that its action must be something more than merely a mechanical one. For example, if a person swallowed a quantity of pins, the chances are they would prove fatal. But their action being mechanical, pins, strictly speaking, are not to be deemed a poison. The phrase, destructive thing, would cover all bodies that taken internally destroy life mechanically, whilst the word poison would include all bodies that kill chemically or physiologically. The question of dose, so far as the sale of poisons is concerned, is immaterial, whilst in trials relating to offences against the person it can be dealt with as it arises.

The Sections 21 and 22 of the 24th and 25th Vict., cap. 100, relating to the use of "stupefying and overpowering drugs," with the object of assisting in the committal of an indictable offence, call for little criticism, although I am not sure, even here, that the word poison would not be better.

There is one point here I should wish to mention, viz. That poisons may be administered in a great variety of ways with equally noxious effects. Besides the mouth they may be given by the rectum or vagina, or injected into the veins, or injected subcutaneously, or applied to broken or unbroken skin, or dropped into the ears, or be inhaled, or as in the case of infants be absorbed in poisonous doses from the mother's milk. This latter fact it is important to remember. Lewald states that more iron can be given an infant by this means than by any other. I have myself found quinine, strychnia, morphia, mercury, bismuth, zinc, lead, arsenic, antimony and iodine in the milk of women to whom these drugs had been administered. That alcohol (a stupefying drug) may pass from mother to child by the breast is a fact of which I have no shadow of doubt. Therefore in all cases it should be understood that the word "administer" should include any possible method whereby poison may find entrance into the body.

I suggest, therefore, that every pharmacist should be required to keep a poison book, in which the date, the name and address of the purchaser, the name and quantity of the article sold, and the purpose for which it was said to be required is stated in all cases where poisons are asked for and sold. The Act provides (Sec. 17) that the bottle, wrapper, etc., containing the poison (that is, not the outside wrapper merely), shall be distinctly labelled with the name of the poison and the word poison, and the name and address of the seller. To this excellent provision I would only add that it appears desirable that "the poison label" should be of some special colour, red suggesting itself as that commonly employed to indicate danger.

I now pass to another part of my subject. The 1868 Act nowhere provides any restriction or lays down any provision relating to the compounding and the sale or delivery of liniments, embrocations, and the like, by pharmacists, medical practitioners or veterinary surgeons; such preparations it must be remembered are often exceedingly poisonous, and have caused (as I can testify) numerous accidental and suicidal deaths. By the 1st section of the 1868 Act, the duty of suggesting regulations as to the dispensing of poisons was referred to the Pharmaceutical Society. It is to be regretted that they have taken no steps to fulfil the obligations thus imposed upon them. The Council of the Society, it is true, did make a suggestion which, with some few alterations (for which I must be held responsible) I shall read to you, fully believing it would meet the case. I regret the members of the Society did not adopt it.

"In the dispensing liniments, embrocations, and lotions, by any pharmacist, medical practitioner, or veterinary surgeon, such liniment, embrocation, or lotion shall be put in a bottle distinctive to the touch, such bottle to be approved of for the purpose by the Councils jointly of the Royal College of Physicians and of the Pharmaceutical Society. Further, there shall be attached to the bottle, in addition, a caution label, also to be approved by the Councils of the Royal College of Physicians and of the Pharmaceutical Society, indicating that the contents of the bottle are for extenal use only."

I have carefully considered the difficulties that have been urged to such a regulation, *e.g.*, the cost of special bottles in the case of the poor—that mechanical contrivances would prevent people from using their common sense—and that by so much greater would be the danger—that a false security would be engendered—that unnecessary alarm might be excited—and so forth. And I admit a certain force in these and in many other kindred criticisms. But then if we wait until we can propose a rule to which no criticisms can be offered, I am afraid legislation must remain at a standstill. We must do our best and leave the rest.

And here I am compelled to tread somewhat dangerous ground in considering how far the precautionary measures regulating the distribution of poisons by pharmacists should apply to apothecaries, veterinary surgeons, and thers. It appears to me inevitable that in the case of medical men and of veterinary surgeons who sell drugs they should be subjected to the same rules that regulate the sale of poisons by pharmacists; whilst in dispensing liniments, embrocations, and the like, it would be scarcely practicable to except them from the precautionary provisions deemed necessary for others.

As regards wholesale dealers, drysalters, etc., no exception is possible. With them the records are, if anything, more easily obtained than in the case of retail traders, whilst the larger quantities dealt with render the necessity for such records the greater. It would, however, be absolutely necessary for some register to be kept of the wholesale druggists, drysalters, etc., entitled to sell poisons, and I cannot think that there could be a better authority to undertake the task than the Pharmaceutical Society.

Beyond this I would stop the sale of poisons altogether. It appears most undesirable that highly poisonous preparations, *e.g.*, the various vermin killers, phosphorus pastes, sheep washes, agricultural solutions, carbolic acid, etc., should be permitted to be sold without the slightest restrictions, often in unlabelled bottles, by grocers, oilmen, and the like. It is most undesirable that herbalists should be allowed to sell such articles as savin, pennyroyal, and other herbs, the procuring of which, we cannot doubt, is in most cases for a felonious object. It is most undesirable that that curious body of herbalists, who bear the ominous name of Coffinites, should be allowed to scatter broadcast their poisonous and noxious preparations of cayenne and lobelia—a mixture, which notwithstanding they assert it not to be poisonous, has, I happen to know, more than once succeeded in destroying the lives of children that have been dosed with it at their hands. If these medicines be required, let them be procured from authorized and registered agents only, and under conditions regulating the sale of poisons.

And now one word on the sale of articles of food adulterated with poisonous drugs. I shall not attempt here to criticize the Adulteration Acts or their working, although the subject is a tempting one. Since the famous work of Accum on 'Adulteration,' published with the startling motto, "There is death in the pot," anxious curiosity has been constantly kept alive by a species of trading on the credulity of the public, and "the press has literally groaned with the efforts of sensational writers on this subject" (Letheby on 'Food,' p. 233). However strongly I may feel that the Adulteration Acts have in many cases worked harshly and unjustly, in one instance I think they fail to go far enough, viz., in cases where the addition of a poisonous body to any article of food can be proved. I do not mean as illustrations of a poisonous body or a body injurious to health, the addition of alum to bread (a perfectly innocuous material within possible limits), or the use of a minute trace of magenta to colour an ice (1 grain of which is enough to colour 2 quarts of custard), but I mean *bonâ fide* poisons in definite quantity, either for the purpose of giving a false strength to a article (*e.g.*, the addition of cocculus indicus to beer), or of improving its appearance (as, *e.g.*, the use of mineral pigments to colour confectionery). In such cases surely a money fine is an insufficient punishment.

Storage of Poisons.

I wish now to draw your attention to the first section of the 1868 Act, regulating the Sale of Poisons (21 and 22 Vict., cap. 121). It provides: "It shall be unlawful for any person to sell or keep open shop for retailing, dispensing or compounding poisons, or to assume the title chemist and druggist . . . unless such person be a pharmaceutical chemist . . . and conform to such regulations as to the keeping, dispensing and selling of such poisons as may from time to time be prescribed by the Pharmaceutical Society with the consent of the Privy Council."

The Act was passed in 1868. This is 1883. What regulations have the Pharmaceutical Society made to regulate "the *keeping* of poisons?" None at all. Any chemist may keep the whole catalogue of poisons named in a toxicological treatise in his shop, labelled as he pleases, in English or in Latin, or in any other language, dead or alive, or even in chemical formula—packed in bottle, paper or box, secured or unsecured, as he pleases, on shelf, or in drawers along with harmless drugs, and constantly required medicinal preparations.

I am sure you will agree with me that some legislation is absolutely called for in this matter of storage. My own experience as a toxicologist would enable me (if it were necessary) to recount more than one case where, owing to poisonous drugs and ordinary medicines being kept on the same shelf, accidental cases of poisoning have occurred.

Let us be fair to the Pharmaceutical Society, to whom was entrusted the duty of deciding what regulations were practicable. The Council of the Society agreed to certain resolutions which were submitted to the members on December 1, 1869. So admirable were these suggestions—the work of thoroughly practical and experienced men—that I shall, with a few alterations, adopt them as regulations I firmly believe would meet the case, and would, if carried out, be of great benefit to the community:—

1. In the keeping of poisons in any shop, dispensary, surgery or wholesale warehouse, each poison shall be kept in a box, bottle or vessel distinctly labelled with the name of the article, having upon it a second distinctive label marked "Poison" (termed a poison label), the precise form of which shall be approved by the Councils of the Royal College of Physicians and of the Pharmaceutical Society.

2. In the storage of poisons one or other or all of the systems following shall be adopted:—

A. The boxes, bottles, vessels or packages used to contain poisons in any shop, surgery, dispensary or warehouse shall be kept in a separate apartment, cupboard, compartment or drawer specially reserved for poisons.

Or, if not so kept apart.

B. The bottles or vessels used to contain poisons shall be distinguishable to the touch and of a form approved by the Councils of the Royal College of Physicians and of the Pharmaceutical Society, and, unlike the other bottles, containing articles which are not poisonous, in the same shop, surgery, dispensary or warehouse.

Or otherwise.

C. The bottles or vessels used in any shop, surgery, dispensary, or warehouse, to contain poisons, shall be tied over, or capped, or secured in a manner distinguishable from the way in which bottles or vessels in use in the same shop, surgery, dispensary, or warehouse are secured for any bottles or vessels containing articles that are not poisonous.

The Pharmacy Act was conceded to pharmacists on the distinct understanding that they would do something for the benefit, and as a safeguard to the satisfaction, of the public in this matter. The Council at that time did do something, but the majority of the members, at their annual meeting on May 18, 1870, rejected their suggestions. I have carefully read and considered all the difficulties urged at the time to their acceptance. The burden of the objection is this:—We do not object to these regulations because they are bad, or even impossible, in fact most of us adopt them, but we do not like to be trammelled. We do take care, says one, in substance, but we do not want to be compelled to take care. We do not want, "says another," an Act of Parliament to make us feel our responsibilities. A third suggested that the convenience of the trade was being sacrificed by such regulations. There were bold spirits at that meeting, who thought and said otherwise. Permit me to quote the words of Mr. Edwards, a well-known pharmacist, who supposes a case (not an imaginary one, as I know of my own knowledge) of a child being poisoned by oxalic acid sold by the pharmacist for Epsom salts. "What," says he, "would the man say as he stood and looked at the cold remains of his child? Has everything been done that would have prevented this accident? Was every precaution taken to stay the hand of death, and keep the silent seal of the destroyer from these cold lips? Am I satisfied that these dangerous things on which the life of my child has been hanging have been guarded and sealed and kept with every possible precaution against accident? Are there no regulations that can affect these things and make these accidents less liable to happen? No, there is no regulation. They, say they (the pharmacists, *i.e.*) know their own business best: they have not known their own business best; and for the last ten years the feeling has been rising that they do not, or these accidents would not happen. It is quite true that some honourable and careful men may, but I want a regulation that will apply not only to the careful and painstaking man, but to everyone: not liberty for some men to do so and so, but a law which shall bind every man. I want it to apply not only to the chemist at the West End, but to the careless druggist who keeps the chandler's shop at the corner of a poor street; to every man who sells poisons, compelling him to take all those precautions that can justly be required before a human life is sacrificed. But regulations were proposed, a string of them were drawn up, but they were objected to and refused. One man said that he did not like putting his poisons in a cupboard; and another said that it was a little trouble to put them in a corner; and another that he did not approve of coloured labels; and there were some other objections of that sort, but it all resolved itself into this, that it was rather more trouble than they chose to take. I can only say this, when these effects come before me, if that is the principle on which these men make laws—if they mind a little trouble—if they think a great deal of an unnecessary precaution—if they are so careless that a little fidgetism even is sufficient ground for rejection—it is high time that other people make laws for them."

The time has come when whoever keeps for sale or dispenses poisons must be ready to accept some legislation in the matter of storage. We shall want no ingeniously devised system of espionage I am convinced to see that regulations, conceived in no spirit of opposition, are efficiently carried out. As regards the sale and storage of poisons, the intelligence and honour of that medical body who compound, as well as prescribe, and of veterinary surgeons, of pharmacists, and of wholesale traders, are certain to render any inquisitorial system—a staff of prying eyes roving up and down the country—as uncalled for as it would be objectionable. Let only fair regulations be proposed, and there is certain to be found both the will and the way to carry them out in their integrity.

I am quite ready to admit that the regulations suggested may not be complete. It is easy enough to criticize any regulations and to talk about false security—about the danger of putting up a fence unless it be perfectly secure, lest people lean against it and fall into the water. But I have yet to learn that *insufficient* legislation is necessarily *useless* legislation. The legislation of 1868 provided for that being done which has not been done. And admitting to the very full the improved education of pharmacists, nevertheless, it is to their interest that everything should be done by them to insure the public confidence which is now and then rudely shattered by a fatal accident, or by the perpetration of an exceptional crime.

And remembering this, that in the case of medical men and pharmacists, as with all other bodies, the sins of an individual member are more or less visted on the entire body, it behoves them to see that all the means indicated by the Act, and other means by which the Act may be supplemented, are duly carried out.

I see no help that medical men who compound as well as prescribe (a combination, I hope, we may before long speak of as a thing of the past), veterinary surgeons and wholesale traders, can be exempted from a certain amount of legislature. For this reason I have suggested that the Council of the College of Physicians should be associated with the Council of the Pharmaceutical Society in deciding what is needful in this respect.

If I have succeeded in placing before you the views I entertain on this enormously important subject, and thereby to provoke a discussion which may help to place the subject of the sale and storage of poisons on a footing more satisfactory to all than it is at present, with the one object of preventing death by misadventure and the commission of criminal acts at once so disastrous, so painful, and so costly, then the object I have had in view to-day will have been served.

Communications, Letters, etc., have been received from Messrs. Abraham, Borland, Mason, Stanford, Benger, Tanner, Stephenson, Dott, Woolley, Ashton, Wyatt, Conroy, Lawrence, Milne, Miller, Bedford, Nind, Quinlan, Siebold, Ekin, Brown, Naylor, Symes, R. F. J., Junior, Apprentice.

THE NEW PHARMACOPŒIAS FOR THE UNITED STATES AND GERMANY.

(*Continued from p.* 144.)

PHYSOSTIGMINÆ SALICYLAS, U.S.P. (new); PHYSOSTIGMINUM SALICYLICUM, P.G. (new).—Assuming that it be desirable that there should be an official salt of physostigmine, it is a decided advantage that the same salt should have been selected in the United States and Germany; but it is rather curious that the choice should have fallen upon one so little known as the salicylate, whilst the sulphate and hydrobromate, which have been informally adopted in France and Holland, are ignored. Presumably the compound meant is the "salicylate of eserine," brought out as a specialty by Merck, about four years since (*Pharm. Journ.*, [3], ix., 976), which was stated to remain exposed to the light three weeks without alteration. The U.S.P. describes it as occurring in "colourless, shining, acicular or short columnar crystals, gradually turning reddish when long exposed to air and light; soluble in 130 parts of water and in 12 parts of alcohol [Merck says 1 in 24 of absolute alcohol] at 15° C., in 30 parts of boiling water and very soluble in boiling alcohol. . . . The aqueous or alcoholic solution of the salt, when exposed to the light for a short time, turns reddish." The P.G. description is practically similar, but allows the crystals to be "free from colour or yellowish." The tests for the identification of the alkaloid appear to be very meagre. The P.G. maximum single dose is 0·001 gram and the maximum daily dose 0·003 gram.

PICROTOXINUM, U.S.P. (new).—The neutral principle prepared from the seeds of *Anamirta paniculata* is another substance that may be said to have obtained a very prompt admission to the Pharmacopœia. The characters given are—"Colourless, flexible, shining prismatic crystals, permanent in the air, odourless, having a very bitter taste and a neutral reaction. Soluble in 150 parts of water and in 10 parts of alcohol at 15° C.; in 25 parts of boiling water and in 3 parts of boiling alcohol; also soluble in acids and in solutions of the alkalies. When heated to about 200° C. the crystals melt, forming a yellow liquid; when heated on platinum foil they char and are finally completely dissipated." The compound is represented by the formula $C_9H_{10}O_4$. Notwithstanding all this precision, it should be borne in mind that it has been recently stated by Barth and Kretschy (*Pharm. Journ.*, [3], xi., 352) that commercial picrotoxin is a mixture of three different bodies in proportions probably varying with the seeds used in its preparation.

PILOCARPINÆ HYDROCHLORAS, U.S.P. (new); PILOCARPINUM HYDROCHLORICUM, P.G. (new).—The hydrochlorate of pilocarpine has been made official in both Pharmacopœias in preference to the nitrate, presumably because of its greater solubility, the hydrochlorate being said to be soluble in about twice its weight of water whilst the nitrate requires 8 parts (*New Remedies*, May, 1881). It is described as in "minute white crystals, deliquescent, odourless, having a faintly bitter taste and a neutral reaction; very soluble in alcohol and in water, nearly insoluble in ether or chloroform." The crystals, which melt and are completely dissipated by heat, give with concentrated sulphuric acid a yellow colour, with nitric acid (sp. gr. 1·400) a faintly greenish-violet tint, and with sulphuric acid and potassium bichromate an emerald green colour. A slightly acidulated aqueous solution gives no precipitate with water of ammonia and solution of soda only produces turbidity in a concentrated solution. The P.G. gives the maximum single dose as 0·03 gram and the maximum daily dose as 0·06 gram.

PIPERINA, U.S.P. (new).—Although this alkaloid has been recommended as a substitute for sulphate of quinine in the treatment of intermittent fevers, the measure of success attending its use would hardly have raised the expectation that it would have been included in a pharmacopœia just yet, especially as it seems quite possible that any favourable results obtained have been due to adherent impurities. The U.S.P., however, does not allow such impurities, for the crystals are to be colourless or pale yellowish, odourless and almost tasteless when first put in the mouth, but on prolonged contact producing a sharp and biting sensation, possibly through a minute portion becoming decomposed into piperidine and piperic acid.

POTASSIUM COMPOUNDS.—The U.S.P., 1880, includes twenty-one potassium compounds, and differs from the previous edition only in omitting impure carbonate of potassium (pearlash), and "carbonate of potassium" that was not quite pure. The P.G., which in 1870 also included three grades of purity of carbonate, now has only two. The U.S.P. contains both the cyanide and the ferrocyanide, but the P.G., 1880, neither; the latter having been dropped out, together with hydrocyanic acid, as no longer required. The other potassium compounds in the U.S.P. and not in the P.G. are "potassa with lime," the citrate, hypophosphite and sulphite. On the other hand the P.G. includes "tartarus boraxatus" (soluble cream of tartar), which is not in the U.S.P. The following are the principal characters of those not in the B.P.:—

Potassa cum Calce, U.S.P.—A greyish-white deliquescent powder, made by rubbing together equal parts of caustic potash and lime. It constitutes the "Vienna caustic powder," and is prepared for use by making it into paste with a little alcohol.

Potassii Cyanidum, U.S.P.—The tests indicate a compound corresponding to at least 90 per cent. of pure cyanide of potassium.

Potassii Hypophosphis (KH_2PO_2), U.S.P.—In white, opaque, confused crystalline masses, or a white granular powder, very deliquescent, odourless, having a sharp, saline, slightly bitter taste and a neutral reaction. Soluble in 0·6 part of water or in 7·3 parts of alcohol at 15° C.; in 0·3 part of boiling water, or in 3·6 parts of boiling alcohol. When heated in a dry test tube it loses adhering moisture and evolves spontaneously inflammable phosphoretted hydrogen. On triturating or heating the salt with an oxidizing agent the mixture will explode. An aqueous solution yields a white crystalline precipitate on the addition of a saturated solution of bitartate of sodium, and with test solution of nitrate of silver a white precipitate that rapidly turns brown and black, separating metallic silver. Acidulated with hydrochloric acid and added to excess of test solution of mercuric chloride it produces first a white precipitate of calomel and afterwards causes the separating of metallic mercury. Tests are given for the absence of carbonate and sulphate and of calcium, and the presence of phosphate is limited to the production of a slight cloudiness when an aqueous solution is mixed with "test solution of magnesium" (a solution of ammoniated magnesium sulphate). It is used in the preparation of "syrup of the hypophosphites."

Potassii Sulphis ($KSO_3 \cdot 2H_2O$), U.S.P.—In white, opaque, obliquely rhombic, octahedral crystals or a crystalline powder, somewhat deliquescent, odourless, having a bitter, saline and sulphurous taste and a neutral or feebly alkaline reaction. Soluble in 4 parts of water at 15° C., or in 5 parts of boiling water; only sparingly soluble in alcohol. When gently heated the salt loses its water of crystallization (18·5 per cent.); at a red heat it is decomposed, leaving an alkaline residue. It differs from hyposulphite in an aqueous solution evolving the "odour of burning sulphur" on the addition of dilute hydrochloric acid and not becoming cloudy. The iodine and starch test given corresponds to at least 90 per cent. of pure sulphite of potassium.

Quinine and other Cinchona Alkaloids and their Salts.—Of the cinchona alkaloids the U.S.P., 1870, included three: cinchonine sulphate, quinine sulphate, and quinine valerianate. No less than eight more have now been added: cinchonidine sulphate, cinchonine, quinidine sulphate, quinine, quinine bisulphate, quinine hydrobromate, quinine hydrochlorate, and chinoidin. The P.G., on the contrary, has dismissed quinine, quinine tannate, quinine valerianate, cinchonine and cinchonine sulphate, and retains only quinine sulphate, bisulphate and hydrochlorate, and chinoidin. It may be stated here that the method adopted in the P.G. for testing the strength of the bark in total alkaloids is the modification of Prollius's recommended by De Vrij (*Pharm. Journ.*, [3], xii., 765). The following are the principal features in the characters and tests of the individual alkaloids and their salts given in the two works:—

Chinoidinum, U.S.P. (new); P.G.—This rather indefinite substance has pretty well dropped out of use in this country,—where indeed it has never been received with any favour,—but it has remained in use in Germany and some other countries, and has now been added to the U.S.P., where it is described as "a mixture of alkaloids, mostly amorphous, obtained as a bye-product in the manufacture of the crystallizable alkaloids from cinchona." It is stated to be almost insoluble in water, freely soluble in alcohol, chloroform and dilute acids, and partially soluble in ether and in benzol. When triturated with boiling water, the liquid, after filtration, should be clear and colourless and should remain so on the addition of an alkali. The P.G. requires that it should dissolve clear in an equal weight of a mixture of 1 part of dilute acetic acid and 9 parts of water so as to leave scarcely any residue; it must also form a clear solution with nine times its weight of cold dilute spirit. Both works limit the amount of ash to 0·7 per cent.

Cinchonidinæ Sulphas, U.S.P. (new).—The neutral sulphate of cinchonidine is made official in the U.S.P., and is described as occurring in white, silky lustrous needles, or thin quadratic prisms, soluble in 100 parts of water or 71 parts of alcohol at 15° C., in 4 parts of boiling water, in 12 parts of boiling alcohol, freely in acidulated water and in 1000 parts of chloroform. the undissolved portions becoming gelatinous. This salt crystallizes from a dilute aqueous solution with 6 to 7 molecules of water, but from a concentrated solution with only 3 molecules. It is the form with 3 molecules which is official.

Cinchonina, U.S.P. (new).—Sulphate of cinchonine was already official in the U.S.P., and now the alkaloid is included. It is described as occurring in white, somewhat lustrous prisms or needles, almost insoluble in cold or hot water, soluble in 110 parts of alcohol at 15° C., in 28 parts of boiling alcohol, 371 parts of ether, 350 parts of chloroform and readily soluble in dilute acids. A solution in dilute sulphuric acid should not exhibit more than a faint fluorescence, showing absence of more than traces of quinine or quinidine; it is distinguished from quinine by its sparing solubility in solution of ammonia, and from quinine, quinidine and cinchonidine by being much less soluble in ether.

Cinchoninæ Sulphas, U.S.P.—Hard, white, shining prisms of the clino-rhombic system, permanent in the air, having a very bitter taste and neutral or faintly alkaline reaction. Soluble in about 70 parts of water at 15° C., or 6 of alcohol; in 14 of boiling water or 15 of boiling alcohol; and in 60 of chloroform; insoluble in ether and benzol. Heated to 100° C. it should not lose more than 4·8 per cent. in weight (two molecules of water); melts with partial sublimation at about 240° C.

(*To be continued.*)

COLD CREAM.*

Mr. Ad. Vomacka gives the following formula and directions for cold cream, in the *Seifenfabrikant*:—

White wax	200 parts.
Spermaceti	500 parts.
Oil of almonds, expressed . . .	1600 parts.
Rose water	80 parts.
Oil of rose, for each 2·4 kilos . .	30 drops.

Melt the wax and spermaceti at a gentle heat on the water-bath, pour the mass into a very shallow, warmed porcelain dish, and let it stand over night covered with paper. Next morning, begin to work the hardened mass by a gentle, uniform to-and-fro motion of the pestle, which should be held lightly between the fingers without exerting pressure, commencing at the edge, gradually working towards the middle, and mixing thoroughly.

The prescribed amount of rose water is now slowly added, in a thin stream, and while constantly stirring. If desired, 5 grams of borax may be dissolved in the rose water, which will facilitate the combination. The mortar is now well covered and set aside for one or two days, in order to give the fat a chance to combine with the water. It is then again briskly stirred for a quarter or half an hour, and, finally, the oil of rose is added, previously dissolved in a little castor oil, which latter imparts to the cold cream an extremely handsome dull lustre. . . .

To prevent cold cream becoming rancid or acid a small quantity of salicylic acid dissolved in rose water or sweet spirit of nitre may be added.

In place of oil of rose, other oils or mixtures of oils may be used, as for instance:—

1. Oil of neroli	10 parts.
Oil of rose	5 parts.
Oil of lemon	15 parts.
2. Oil of bergamot	9 grams.
Oil of lavender (finest)	3 grams.
Oil of rose	35 drops.
3. Oil of lemon	5 parts.
Oil of lavender (finest)	5 parts.
Musk	0·4 parts.

In the same manner as the above is prepared.—

Vaseline Cold Cream.

Spermaceti	150 parts.
Paraffin	150 parts.
Vaseline, white	1000 parts.
Rose water	600 parts.
Oil of rose, to every 2·4 kilos . .	30 drops.

Advertisements, and payments for Copies of the Journal, Messrs. Churchill, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE PRESIDENT OF QUEEN'S COLLEGE, GALWAY, ON THE EXAMINATION SYSTEM.

It is so short a time since the subject of examinations occupied these columns that some apology for referring to it again after such a brief interval might be fitting, were it not that the report recently presented to Her Majesty, by Professor Moffett, as President of Queen's College, Galway, contains something like a defence of the examination system which it is now becoming rather fashionable to decry, and moreover the report deserves special attention as expressing the opinions of an official holding an important educational trust. Professor Moffett in the outset recognizes the rapid extension of the examination system—particularly in its competitive form—and the predominant part it has begun to play in the general education of the country. He admits that it bids fair to become the director and regulator of education and to modify profoundly the old methods of instruction. But he is not prepared to acquiesce in an indiscriminate condemnation even of the competitive examination system and evidently is not terrified by the prospect of any near advent of the time—apparently perceptible to some—when competition between schools to provide teaching that shall pay in the way of immediate and material results rather than the teaching which is really fruitful and informing shall have converted the whole educational machinery of the country into an apparatus for encouraging and facilitating "cram." Indeed, even the much decried practice of "cramming" is not, in Professor Moffett's eyes, an unmitigated evil, since he considers that it is at least a reaction against the slow teaching, the drowsy and sterile routine of the old educational methods. It may be presumed that this toleration would hardly extend to some forms of teaching that are usually included under the name "cram," such, for instance, as those referred to humorously by Professor Foster in his address. Still Professor Moffett deliberately expresses his opinion that some of the objections that have been urged against methods to which the term "cramming" has been applied are theoretical and illusory, and appear to "ignore the conditions of modern "existence, the pressure and competition of actual "life, 'where every gate is thronged with suitors'" and where every appointment is sought by a crowd of candidates. So long, he adds, as the results of examinations possess the influence they actually exercise on the prospects of candidates, so long will the "cramming" method, which is a product of the competitive system, justify its existence.

Professor Moffett argues that it is necessary to recognize facts as we find them, and, whilst never losing sight of the ideal of education, to make a perfectly candid use of the opportunities which the circumstances of the country and the time afford. The system of examinations is one of these facts, and the question now is not whether we will have examinations, but what kind of examinations we will have. But when the Professor comes to reveal his mind upon this subject it is seen that his opinions are hardly so revolutionary as might have been surmised from his *quasi* defence of "cram." In fact, he adopts the opinion of Professor Vaughan, that the work to be effected by good examinations is to exclude as far as possible the favours or injuries of chance, to foil the arts of cram, to apportion the success to the industry, the talent and the good sense of the students, and so indirectly to secure good teaching and good, energetic, honest learning. In this definition there is nothing that might not be endorsed by the most orthodox of teachers. But Professor Moffett would go farther than this, and instead of remaining satisfied with such an indirect influence of examining boards upon teachers and taught, would accord to them a function which many will deem should remain in other hands. He would have examiners regard themselves not merely as judges of the students who come before them, but to some extent also as directors of the teaching of those who will follow, and, therefore, aim at making their examinations "educational agents, as guides of teaching and of study." This, however, would seem to reverse the usually accepted position of examiners and imply that they should be at liberty to travel beyond the subjects in which the candidates go up for examination, and to put questions in other subjects, not because the candidates are supposed to have been taught them, but simply because in the examiners' opinion such subjects ought to be included in the curriculum of succeeding students.

Professor Moffett's arguments appear to us to be somewhat sounder when he passes from the subject of the aims of the examiners to that of the examinations themselves. The application of the examination test, pure and simple, has, he considers, a tendency to engender certain well-known intellectual defects, of which the chief is the habit of loading the memory with the mere results of knowledge rapidly accumulated, which, when the pressure is passed, is almost as rapidly forgotten; in fact, it tends to foster "cram." He prefers that examinations should be the sequel of well-ordered courses of study and a test of the thoroughness with which a curriculum has been pursued. As to the manner of conducting such tests the Principal of Galway College has great faith in a searching oral examination, as giving more efficient and trustworthy evidence as to the fulness and coherence of a student's knowledge than is afforded by written answers. He would, therefore, extend the *vivâ voce* portion of mixed examinations as far as possible, and give it a greater importance by assigning to it a higher value in the aggregate of marks.

On the whole it will be seen that whilst holding somewhat charitable views as to the nature and extent of the evils that follow in the wake of examinations which are prepared for and passed from more or less commercial—but not necessarily unworthy—motives, Professor Moffett is in accord with the majority of other experienced teachers as to the most effective means of minimizing the evil, and would ensure that the student during at least a portion of his pupilage has been undergoing a sound and honest course of education.

PHARMACEUTICAL EDUCATION IN FRANCE.

Those of our readers who followed Mr. Möller in his very excellent account of modern pharmaceutical study in the different countries of Europe, which two years ago appeared in this Journal, will perhaps remember that besides the three "Superior Schools of Pharmacy" in France, at Paris, Montpellier and Nancy, and the mixed faculties of medicine and pharmacy at Lille, Lyons and Bordeaux, the State also conducts sixteen preparatory pharmaceutical schools in different parts of that country, in which the educational curriculum necessary for qualification to practise as a pharmacien may be followed by those persons who only aspire to belong to the second class. These schools have recently been reorganized and a decree has been issued regulating the conditions under which they are in future to be carried on, and although there are no analogous establishments in this country, and are never likely to be, it may prove interesting at a time when the subject of compulsory pharmaceutical education is again receiving special attention to refer to some of the arrangements so far as they relate to the teaching of pharmacists.

The authorized teaching staff in these schools is to include twelve titular professors, six assistant-professors, and two superintendents of practical work, besides subordinate officials. Of the twelve professorial chairs, four are to be devoted to chemistry and toxicology, physics, natural history, and pharmacy and materia medica, the other eight being associated with more specially medical subjects. One of the six assistant-professors is to be attached to the chairs of physics and chemistry jointly; another to the chair of pharmacy and materia medica, and a third to that of natural history. The qualification for a professorship of physics, chemistry or natural history is to be the degree of doctor of medicine or that of pharmacien of the first class; but only a pharmacien of the first class can hold the chair of pharmacy and materia medica. The assistant-professors will be required to hold similar diplomas, except in the case that a licence in the natural and physical sciences will be accepted to teach according to the nature of the licence. The superintendents of practical physics and chemistry will have either to possess diplomas as doctors of medicine or as pharmaciens of the first class or be licentiates in physical science. The appointments as assistant-professors are to be for a period of nine years, and, as a rule, will be decided by an open competition conducted by a faculty of medicine, a mixed faculty of medicine and pharmacy or the authorities of a superior school of pharmacy, as determined by the responsible minister; but the right is reserved to the minister to appoint assistants to the chairs of chemistry, physics, and natural history, without competition. Nine years is also to be the term of the appointments as superintendents of practical work, and these are to be dependent upon the results of open competitions conducted by the authorities of the schools in which the vacancies occur. A table of the courses of lectures delivered by the professors and their assistants and the practical work done in each school, and containing full information as to the teaching, has to be submitted to the minister. The entire expense of these establishments is to fall upon the cities in which they are situated, the respective authorities entering into an engagement to pay the cost of teaching, repairing buildings, furniture, collections, laboratories, botanical gardens and clinics. It would seem probable that if the proposition to do away with the distinction between the first and second grades of pharmacien should become law, these schools would assume additional importance.

Another decree has been issued creating two new preparatory schools at Nancy and Bordeaux in connection with the Sanitary Department, to which students are to be admitted to be trained as doctors and pharmacists for service in the army. Some details may be quoted from this decree to supplement the information recently given in these columns as to the position of pharmacy in the army in Austria. The pharmaceutical competitors will be required to be between seventeen and twenty-one years of age at the time of entry, certified to be skilled in military service, possess the university diplomas necessary for ordinary pharmaceutical studies, and have finished a stage of two years. All the pharmaceutical pupils will study in the school at Nancy, and a charge of £40 will be payable annually for board as well as a sum for outfit; but both these payments may be wholly or partly remitted at the discretion of the minister, though even then, if the pupils fail, they are to be liable to reimburse the money. Pupils in the school at the age of eighteen are to be held to have contracted an engagement of five years. When a pupil attains the diploma of pharmacien of the first class, he is to pass with the rank of second class *pharmacien aide-major* to the Val-de-Grace Hospital, Paris, where he will receive pay according to his rank, augmented by a sum of £20 for the expense of his first outfit. After remaining in the hospital a year he is to undergo a final examination, the result of which will determine his position in the service.

The Hampstead Vestry appears to have repented of its recent raid upon chemists, since, at its meeting on the 11th inst., it passed a resolution to the effect that, pending the issue of a new Pharmacopœia, it is undesirable to prosecute chemists under the Sale of Food and Drugs Act respecting sales of spirit of nitrous ether, B.P., provided that the article sold be not of greater specific gravity than that recognized by the London Pharmacopœia, "the present form for making the article being recognized as unsatisfactory by the best authorities." The resolution was moved by Mr. Preston, seconded by Mr. Beeton, supported by two medical practitioners, and accepted with only one or two dissentients. "A fault confessed is half redressed," and therefore it would perhaps not now be graceful to object that if the vestry had consulted those of its colleagues acquainted with the subject before instead of after stirring up the public analyst it might have escaped the penance. With respect to the resolution, however, we would suggest that in future the vestry, when making known its decisions, should follow a well-known and safe rule, and abstain as far as possible from giving its reasons.

* * *

Although, as mentioned recently, one of the principal objects for which the National Retail Druggists' Association was recently established in Washington is to exercise a control over the selling of proprietary articles, expressions of opinion were not wanting in the discussion that such sales are not directly or strictly speaking the vocation of the druggist. One speaker argued that any tyro in a country store can sell a proprietary article as well as the best educated chemist and druggist, and that when the pharmacist does sell it he does so not in his capacity as a druggist or as a pharmacist, but in his capacity as a merchant. He admitted that nevertheless if such things are to be sold it would be better that they should be sold by persons competent to speak a word of caution to the purchaser when dealing in dangerous preparations, but considered that this could only be regulated by public opinion.

* * *

At a Conference of the Teaching Colleges of Pharmacy recently held in Washington, it was resolved that from the year 1885 an attempt should be made to enforce a better scholastic education as a condition precedent to entering the technical colleges, and that in future more time should be given and importance attached to practical instruction in the laboratory.

* * *

The next meeting of the American Pharmaceutical Association, which now numbers about fourteen hundred members, is to be held at Milwaukee, Wisconsin, on the last Tuesday in September, 1884. The new President is Mr. W. S. Thompson, of Washington.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN EDINBURGH.

October 10, 11 *and* 12, 1883.

Present on each day—Mr. Atkins, Vice-President; Messrs. Ainslie, Baildon, Clark, Gibson, Gilmour, Kininmont, Nesbit and Stephenson.

Professor Maclagan attended on each day on behalf of the Privy Council.

MAJOR EXAMINATION.

10*th.*—*One* candidate was examined, and was declared qualified to be registered as a Pharmaceutical Chemist:—

Pirie, William ....Arbroath.

MINOR EXAMINATION.

10*th.*—*Thirteen* candidates were examined. *Eleven* failed. The undermentioned *two* passed, and were declared qualified to be registered as Chemists and Druggists:—

Allan, Henry Wemyss Fielden.Glasgow.
Bostock, Thomas Henry.........Eastwood.

11*th.*—*Twelve* candidates were examined. *Six* failed. The undermentioned *six* passed, and were declared qualified to be registered as Chemists and Druggists:—

Hedley, Charles Alfred ....South Shields.
Hutton, Robert Sanders ....Darlington.
Jackson, Harold ....Manchester.
Laing, George ....Edinburgh.
McGregor, James..................Edinburgh.
Maxton, William ....Edinburgh.

12*th.*—*Sixteen* candidates were examined. *Eight* failed. The undermentioned *eight* passed, and were declared qualified to be registered as Chemists and Druggists:—

Morris, Henry Ridley ....Ipswich.
Mowatt, John Watt ....Coatbridge.
Reynolds, Edwin ....Edinburgh.
Sharp, John ....Galashiels.
Stevens, George ....Cannock.
Sutherland, Donald ....Aberdeen.
Thomson, Isaac William..........Edinburgh.
Whyte, James ....Aberdeen.

PRELIMINARY EXAMINATION.

The undermentioned was received in lieu of the Society's Examination:—

Certificate of the University of Edinburgh.

McGarth, Thomas Elder.........Leith.

Pharmaceutical Society of Ireland.

MEETING OF THE COUNCIL.

On Wednesday, the 3rd inst., the monthly meeting of the Council of this Society was held at No. 11, Harcourt Street, Dublin, at 3 o'clock.

The President, Mr. Brunker, in the chair.

The other members present were—Mr. Draper, Vice-President, and Messrs. Allen, Bennett, Doran, Evans, Grindley, Hayes, Hodgson, Minchin and Wells, Drs. Montgomery and Aquilla Smith and Professor Tichborne.

The Registrar read the minutes of the last meeting of the Council, which were confirmed.

Mr. Grindley asked to have the minutes of the Annual Meeting read.

The Registrar said the practice had been to read and confirm the minutes of the Annual Meeting at the meeting of the Council held in November.

A letter was read from Dr. Kaye, Q.C., Clerk to the Privy Council, stating that the resolution of January 3, 1883, was still under consideration.

A letter was read from Mr. James N. Hardy, L.P.S.I., enclosing case and counsel's opinion upon the legal status of his compounding establishment.

On the motion of Mr. Bennett, seconded by Mr. Doran, the letter and opinion of counsel were referred to the Law Committee, who were authorized to take counsel's opinion thereon if necessary; and the Registrar was directed to inform Mr. Hardy of what had been done.

A letter from Mr. Patrick Joseph Finegan, dated 48, Henry Street, September 22, asked the Council to exempt him from the operation of the new rule, requiring four years' study of practical pharmacy, on the grounds that he had entered for the Preliminary examination before the passing of the rule, and that on September 7 he apprenticed himself for two years to Mr. Allen, a member of the Council.

Mr. Allen: I was not aware that he had written that letter; but, as a matter of fact, he is with me for two years, but on the understanding that if the decision of the Council should be against him he will have to serve the remaining two years.

The President: This gentleman presented himself at the Preliminary examination early this year and failed to pass. Then he came under the operation of the proposed new rule (which has not yet been sanctioned by the Privy Council), which requires that a candidate shall have four years' experience in practical pharmacy before he presents himself for the examination for the licence. He has since passed his Preliminary examination, and what he wants the Council to do is to put him in the same position as if he had passed the Preliminary examination at the time at which he failed. The difficulty is, how can we bind the Council which will be in office two years hence?

Dr. Montgomery: They would doubtless be guided by the opinion of the present Council.

After some discussion, on the motion of Mr. Hayes, seconded by Mr. Grindley, it was resolved—

"That Mr. Finegan's request to be admitted to the Final examination after two years' apprenticeship be on the merits of the case granted."

A letter was read from Mr. Joseph Edmondson, M.P.S.I., relative to the supply of the *Pharmaceutical Journal* to members.

The President: As it was decided at the Annual Meeting that the Journal should be continued for another six months, at present there is no occasion to go into this matter.

A report was received from the Certificate Committee.

Mr. Grindley moved, pursuant to notice:—

"That reports of Committees, recommending new rules or changes in the regulations of the Society, be not passed until they have been considered at two stated meetings of Council."

His object was to make sure that propositions of the sort would be in the hands of members of the Council a sufficient time before being brought forward, in order that they might have a full opportunity of considering them. The inconvenience of the present practice was illustrated lately, when the Council recommended the establishment of a new grade, which he thought was at variance with the wishes of the general body of the licentiates.

Mr. Wells seconded the motion. Another instance of the inconvenience of the practice of the Council not being such as was proposed was afforded when the late President got a resolution passed in reference to the supply of the Journal, and had no opportunity of being subsequently present when another resolution of quite a different character was passed.

Professor Tichborne said the resolution as it stood seemed to contemplate that the same subject should be discussed at two successive meetings of the Council, which certainly would be objectionable.

Mr. Grindley: This resolution does not relate to every matter, but only to important changes in the rules and regulations.

Mr. Hodgson: Such proposals might be brought up at one Council meeting and discussed at the subsequent one.

After some further discussion, the resolution was passed in the following form:—

"That reports of Committees and notices of motion recommending new rules or changes in the regulations of the Society shall not be discussed until the second stated meeting after their presentation."

In reply to Mr. Wells, the President said that any member of the Society who fell into arrear with his subscription would have either to pay up the arrear or be proposed as a new member.

Some financial business was then disposed of, after which the Council adjourned.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The Annual Meeting of the thirty-fourth session of the above Association was held at the Royal Institution on Thursday, September 27. The President, Mr. Joseph Woodcock, occupied the chair.

The minutes of the last meeting were read and confirmed, and the following donations announced:—The *Pharmaceutical Journal* and a complete series of specimens of Darjeeling Cinchona Barks, from the Pharmaceutical Society; the Smithsonian Reports for 1870, 1873, 1874, 1875 and 1878, from the Institution; the 'Proceedings of the American Pharmaceutical Association,' from the Association; the 'Scientific Proceedings of the Ohio Mechanics' Institute,' from the Institution; the 'Annual Report of the Liverpool Naturalists' Field Club,' from the Society; and the *Canadian Pharmaceutical Journal*, from the Editor.

The following were then elected as Members or Associates, viz.:—Associates—Messrs. Alfred Evans, F. Hornblower, W. T. Salkeld, James Shacklady, jun., H. Edward, F. Park and G. J. Poore.

The President, after a few words of welcome to the members, called upon the Secretary to read the report of the Council, which was done, and was followed by the Treasurer's statement of accounts.

The President moved:—"That the reports as read be adopted, and together with a list of members and abstract of proceedings of the past sessions be printed and circulated among the members." He, at the same time, referred to the retirement of Mr. John Shaw from the Council, and, indeed, from the Association. He alluded to Mr. Shaw's long connection with the society and the many services which he had during that time rendered to it both as an officer and as a member of the Council.

This motion was seconded by Mr. E. Davies, and carried unanimously.

Proposed by Mr. R. Sumner, seconded by Mr. Parkinson, and carried unanimously:—"That the best thanks of this meeting be given to the donors to the Library and Museum, and to the authors of papers, during the past session."

A vote of thanks was then passed to the officers and Council for their services during the past session, after which the election of four memhers of Council was proceeded with.

The proceedings then terminated.

HAWICK PHARMACEUTICAL ASSOCIATION.

The October meeting of the above Association was held in the Chemical Laboratory, on Friday, October 5, Mr. Maben, President, in the chair.

Mr. James A. Hislop read a paper on "The Preparation and Preservation of the Infusions and Decoctions of the B.P.," in which he directed attention first to the manipulation of the several operations involved in the production of a perfect infusion or decoction. Having pointed out the liability of fresh infusions to deteriorate, and discussed the causes of this deterioration, he gave the results of several experiments which had been undertaken in order to ascertain the relative power of certain preservatives. The first was a physical remedy and consisted in hermetically sealing the mouth of the vessel containing the infusion, which had previously been heated to 100° C. Infusions thus preserved kept good for an indefinite period, but on re-opening the bottle decomposition rapidly took place. One grain of salicylic acid to each ounce of infusion prevented decomposition for several weeks, and boracic acid gave similar results. Infusion containing 1 grain of glacia line to each ounce showed signs of decomposition within a week. Glycerine and borax in the proportion of 10 minims to each ounce prevented deterioration for a month, but after that time, traces of decomposition presented themselves. Mr. Hislop said that if the addition of chemicals could be at all justified, glycerine and borax would be found to possess preservative power, without any of the objectionable effects of some of the others, though it was possible to keep an infusion without chemicals in the manner already pointed out. Mr. Hislop then discussed the question of fresh *versus* concentrated infusions, his conclusion being that the former should be used, as they were in all respects a better preparation, the odour and flavour of the concentrated being distinctly inferior. Further, they were the official preparation, and the concentrated article should not be used unless sanctioned by authority.

On the motion of the Chairman a hearty vote of thanks was awarded to Mr. Hislop.

The next paper read was—

The Preservation of Medicinal Herbs by Ensilage.

BY F. J. B. QUINLAN, M.D., M.R.I.A.,

Professor of Materia Medica, Pharmacology and Therapeutics, Catholic University; Examiner in the same, Royal University of Ireland.

Both the practising and pharmaceutical branches of the medical profession are agreed as to the advantages of fresh medicinal herbs over the same substances in a dried condition, and a simple process which would supply fresh herbs all the year round has long been a desideratum. In the summer months of the year fresh indigenous herbs are of course forthcoming, but during the remaining time our resource has hitherto usually been herbs dried by being hung up in a loft, or perhaps by artificial heat—and it is unnecessary to dilate here upon the inadequacy of herbs so treated. In the hands of the pharmaceutical worker they frequently fall into powder, and often he is unable to distinguish between genuine herbs in their dried state and their spurious congeners. For example, I lately made a careful microscopic examination of the stock of *Conium maculatum* in the loft of an eminent wholesale establishment, and found that it consisted mainly of *Æthusa Cynapium*, or fool's parsley; and this without the least reflection upon the honesty of the establishment, for I am certain that the adulteration arose partly from the ignorance of the gatherers, and partly from the difficulty of distinguishing between the two plants in their dried condition. The physician complains of the inferior physiological activity of the tincture, made from the dried leaves: for example, tincture of hyoscyamus, made from the fresh leaves, will, if dropped into the eye, cause marked dilation of the pupil; whereas the tincture made from the dried leaves causes no such reaction. In fact, I knew an instance where such tincture was returned with a query whether it was not tincture of belladonna. The first person who directed my attention to this point was the late Mr. Donovan, of Dublin, the eminent originator of the solution of arsenic, iodine and mercury, called after him. Mr. Donovan had a tincture of digitalis which was much relied upon, and he told me that in making this tincture he brought the alcohol to where the foxglove was growing, took the plant from the ground, bruised it and plunged it in the spirit. He maintained that tinctures, to use his own words, "should be made from the live plant," and I believe that he was right. I may here express my doubts respecting tinctures; they are no doubt convenient and handy, but the question arises whether the ethylic alcohol extracts the virtues of all herbs—in the case of laudanum it certainly takes up as well the stimulating and injurious properties of the opium. This is unanimously admitted, and in latter years this old and celebrated tincture has for internal use been almost superseded by black drop, (the manufacture of which has been successfully revived in Dublin), by Battley's sedative, the fluid extract of the Pharmacopœia, and other cognate preparations. An effort has been furthur made to preserve the active principles of fresh herbs by the "succi" first* suggested to the profession in 1835, by Mr. Squire, and by the green extracts. The preserved juices of conium, scoparium and taraxacum at once made their mark, and those of belladonna and hyoscyamus have been added; and it would not be too much to say that they have almost completely superseded the cognate tinctures. Speaking of the juices, I may express my regret that the framers of our Pharmacopœia selected ethylic alcohol for their preservation, and not glycerin alcohol, which would answer just as well and would not have an injurious effect in many cases of internal irritations. The green extracts are no doubt valuable preparations, but it is my experience that, if made exactly according to the Pharmacopœia, they will not keep through the autumn and winter. If, however, a supply of herbs in a practically fresh condition could be maintained all the year round, much benefit would accrue to the succi, the green extracts, and to some tinctures, both in regard to ease and simplicity of preparation and to efficacy of action.

I venture to bring under the notice of the Conference a simple plan of accomplishing this most desirable object by the method of ensilage; and, without the delay of describing the various modes tried, I will briefly explain the one which has succeeded perfectly. In doing so I must tender my acknowledgments to Dr. John Evans, Apothecary to the Queen and to the Prince of Wales, who placed his pharmaceutical laboratory at my disposal, and had the various silos prepared. The herbs in a perfectly fresh state are bruised to a pulp in a mortar, and then placed in glass bottles; being well tamped down until there is just room for the glass stopper, which is then forced in so as to exclude *every particle* of air, and the whole top is encased in beeswax softened by heat. This is the best capsule: tar is too dirty, sealing wax is apt to crack, and bladder rots. These bottles are now buried in the ground at a depth of three feet; and so treated, belladonna, conium and other herbs have kept for four months perfectly sweet and fit for pharmaceutical purposes. From what I have seen of agricultural ensilage I have no doubt that the bottled herbs would keep for six or even eight months, or perhaps longer. Of course every now and then a bottle will fail from imperfect manipulation, and that often without visible cause, most likely from a little air having been left in. When the bottle is taken out of the ground this failure is at once rendered evident by the spots of mildew appearing in the vegetable. I exhibit two specimens thus spoiled, one wholly and the other partially so.

* *Pharmaceutical Journal*, vol. i.

The factors of the decomposition of vegetables are the putrefactive germs contained in the air, the actinic rays of the sun, heat and moisture; and their comparative influence is shown by the following simple experiment:—Four bottles were filled with fresh leaf pulp, as already described, and were closely corked; the corks, however, were not tied or waxed. Nos. 1 and 2 were exposed to the light, but not to the direct action of the rays of the sun, the cork of No. 1 being left loose and that of No. 2 being driven very tightly in. No. 3 was put beside the others but covered by a nest of three earthen jars, one over the other, so as to expose it to the same temperature but not to light. No. 4 was buried in the ground. In thirty-six hours there was mildew and a putrefactive smell at the mouth of No. 1, and the cork of No. 2 was blown clean out by putrefactive gas. In sixty hours there was mildew in No. 2, and the cork of No. 3 was loose, but No. 4 was unaffected. Of course No. 4 would not long remain so, as the ensilage was imperfect. This experiment is useful as showing the conditions which must be avoided; and I may add that a locality shaded from the sun must be selected, and that no place answers better than a roofed shed with a free circulation of air—which will keep the soil quite dry.

There is a special class of medicinal herbs for which ensilage is indispensable, viz., those which must be used in the fresh state. An example of this is the *Galium Aparine*, which is now much employed as a dressing for ulcers and cancers. This plant is bruised fresh, made into a kind of poultice, and placed upon the sore.* By ensilage only can it be used in winter and spring.

It is unnecessary and would here be unsuitable to dilate upon the success which farm ensilage has attained in the hands of American and continental agriculturists. There is, however, nothing new in the discovery or rather revival of M. Gouffart. It was practised thousands of years ago by the ancient Egyptians, and is depicted in their tombs; it was worked in Prussia and in Spain from time immemorial; and the well-known Irish potato pit, which preserved "the murphies" so fresh and good, was a rude ensilage. Still more to the point, however, is the plan of our grandmothers, of preserving green gooseberries. These worthy old ladies, who might perhaps give some useful hints to the housekeepers of to-day, used to pack the green gooseberries tightly in tall wide-mouthed bottles, a small quantity of water being added. These bottles were placed standing in a pan of water, which was very gradually raised to the boiling point. A copious steam now rose from the bottles partly from the water and partly from the gooseberries; and at the right moment when the steam was in full vent and the water just boiled away, the bottle was corked, withdrawn from the water, tied securely, and waxed, and without delay buried in the ground. I have frequently in the depth of winter eaten well-flavoured gooseberry pies so produced; and the process is interesting as showing the possibility of ensilage† on the scale suitable to the wants and capacities of the pharmacist whether on a large or small scale. Addressing a practical audience it is of course hardly necessary to add that an ensilage bottle once opened, like a bottle of claret, must immediately be made use of.

The PRESIDENT remarked that Dr. Quinlan had raised several questions besides the one which gave the title to the paper, such as the pharmaceutical value of dried herbs, the claims of fresh juice as against green extracts, and so on. He thought he must decide that, while thanking him for all he had written, the members must in the discussion confine themselves to the main point of the preservation of medical herbs by ensilage. He was sure all would agree in giving Dr. Quinlan a hearty vote of thanks for his paper.

* *British Medical Journal*, June 16 and July 9, 1883.

† Any reader desirous of seeing a short but sufficient account of the agricultural aspect of ensilage can refer to the illustrated pamphlet by Mr. Thomas Christie, F.L.S. London, Christie and Co., 155, Fenchurch Street, E.C., 1883.

A vote of thanks having been passed,

Mr. EKIN asked Dr. Quinlan if he had taken note of the temperatures at which he preserved the plants. He understood him to say that success was due to the exclusion of the air; but he presumed that only meant outside infected air, because the very process of ensilage was dependent on a certain amount of air being shut up in the green vegetable. Some experiments had just been published, which were detailed to him by the gentleman who made them, before publication, and they promised to throw a new light on the whole matter. This gentleman had experimented for years on silos, and had paid great attention to the temperature. He found that a certain fermentation went on, and the temperature of the whole mass must then be raised beyond 50° C. when the germs became sterile, and green fodder would keep indefinitely. It would be quite possible to admit filtered air to this fodder after it had reached this stage, and unlike Dr. Quinlan he seemed to lay no stress at all on the exclusion of light. The failures which had hitherto taken place arose from the whole mass not having been raised to the necessary temperature. There was an immense field for this process pharmaceutically, but it was yet in its infancy, and a great deal of further observation was required. He hoped Dr. Quinlan would continue his researches and report again, but it occurred to him that the fermentation and high temperature necessary to success would in some cases act prejudicially on the active principles of the plants.

Dr. SYMES said Dr. Quinlan had done good service by calling attention to this method, but he did not think it could fairly be called ensilage. As Mr. Ekin had said, in ensilage as practised by agriculturists a certain amount of air was present and fermentation ensued, and if that fermentation occurred in the bottles it would probably be the initial stage in the destruction of the active principles. The practice of Dr. Donovan, which had been cited, seemed to show that herbs should not be kept even in the fresh state after they had been gathered; and it was well known that if roots were to be dried, the less they were crowded together, and the sooner they were placed in a position where they would dry rapidly, the better they were preserved. He took it the process depended on the exclusion of air, and would suggest that one of the bottles should be placed under the receiver of an air pump, with some arrangement for forcing in the stopper when the air had been exhausted. One of the experiments quoted seemed to indicate that there was some advantage in burying the bottles, but it seemed to him that if they were sealed as perfectly as was described, and then placed in a cool dark place, the result ought to be equally good.

Mr. STANFORD asked whether this process did not alter the medicinal character of the plants; because in all the agricultural specimens he had seen, the fodder was quite different to the original plants. He should think an ensilaged plant would differ as much from the original as sauerkraut from cabbage.

Mr. PLOWMAN asked whether the statement that tincture of hyoscyamus made from the fresh leaves dropped into the eye caused dilatation of the pupil, whereas that made from dried leaves did not, was founded on observation.

Dr. QUINLAN said the statement was founded on his own experiments.

Mr. PLOWMAN said he was about to remark that hyoscyamus leaves varied very much in quality. The mydriatic action was due to one or more alkaloids, and it seemed almost incredible that a tincture of fresh leaves should possess this action, while a tincture of the same leaves carefully dried at a low temperature should have the natural alkaloidal salts so altered that this action should be destroyed.

Mr. HOLMES, referring to *Galium Aparine*, asked if Dr.

Quinlan considered it to be as active in the ensilaged state as when fresh. He should also like to know if Dr. Quinlan had formed any opinion as to what the preservation was due. It was understood that in ordinary ensilage a small amount of alcohol was formed, which would naturally act as a preservative.

Mr. WILLMOTT suggested that Dr. Quinlan should continue his experiments. It must be a difficult matter to expel the air completely from the bottles; and even then it was a question how far the elements of decomposition were present in the plant itself. Some time ago he had occasion to carry out some experiments in which it was necessary to exclude the air, and to expose the product to a considerable temperature, and found that a higher point than that mentioned by Mr. Ekin was necessary. It was a question how far this would affect the qualities of the plant.

Dr. QUINLAN said it would be evident from the character of the paper and the time when he commenced the investigation that he did not bring this forward as a completed communication, but simply as one worthy of inquiry and discussion. The question was in its infancy, and his principal reason for now introducing it was in order to get additional light upon it from the various scientific and practical men before whom it was read. That expectation had been amply fulfilled, and he should now, he hoped, be able to carry on the investigation to a complete and satisfactory result. Next year he trusted to have the oportunity of stating further results, obtained with the advantage of the suggestions which had now been made. He might tell Mr. Ekin that he was quite aware of the importance of temperature. He was induced to take up the matter from seeing ensilage going on in Belgium last summer, and there, after the stuff had been cut, tamped down and covered, they occasionally ran a tube down into it with a thermometer, and if the temperature was above a certain point it was known that the silo was "done for." Of course the only object of excluding air was to exclude germs, in the same way as the old surgeons, who knew nothing about germs, always endeavoured to exclude the air from a wound; he should not have any objection to filtered air entering the bottles. Dr. Symes's suggestion about the air-pump was very valuable, and he would endeavour to act upon it; and he would also place registering thermometers in the bottles buried in the ground. He found that there was a distinct advantage in burying the bottles. Mr. Stanford's question was one which he could not as yet even approach, not having had an opportunity of testing the medicinal character of the herbs so preserved. This was the keystone of the arch and if it fell out he would take care to report the collapse which would follow. The fermentation and sweet taste which arose in ensilage was well known to every one. He was obliged to Mr. Plowman for putting the question he had, and migh state further, that the two samples of tincture of hyoscyamus were obtained from Dr. Evans's establishment, and were both made from the biennial plant, in one case fresh, and in the other dry. The one made from the green plant caused dilatation of the pupil; and a case occurred where the tincture was sent back with a query whether it was not tincture of belladona. The question whether decomposition took place could only be solved by further experiment. He thought probably some herbs would silo well, some middling, and others not at all, but he should continue the experiments and report the result next year.

The next paper read was on—

THE MULLEIN PLANT.

BY F. J. B. QUINLAN, M.D., M.R.I.A.,

Professor of Materia Medica, Pharmacology and Therapeutics, Catholic University, Examiner in same, Royal University of Ireland.

The therapeutic action and properties of the mullein plant have been thoroughly discussed in the medical journals,* and it is my intention, therefore, on the present occasion to view it in its pharmaceutical aspect only. As this drug is new in pharmacy I may mention that in the early stages of pulmonary consumption it has a distinct weight-increasing and curative power, similar to that of cod liver oil or of Russian koumiss; and that it is superior to either in the point of view of comfort to the patient. The repulsion and even disgust with which cod liver oil is swallowed by multitudes of invalids is well known; and the fact that many thousands of gallons are annually thus consumed is a sure proof of the potency of a medicine which, however, many phthisical invalids are unable to swallow at all. Koumiss, as made at Samara, in Russia, from the milk of mares, is very agreeable and s a better weight-increaser than even cod liver oil. It will not, however, bear travelling, and to go through the koumiss cure the sufferer must accomplish the long and tedious journey to Samara, in Southern Russia.† The koumiss manufactured in these countries from cow's milk is, for the chemical and physiological reasons adduced by Dr. Carrick, a very ineffectual substitute for its Russian namesake, made from the milk of the mare. Mullein is, as I shall presently show, a very palatable and agreeable remedy, and is much liked by the patients, and has, I believe, a great future of usefulness before it. I have found it equal to cod liver oil; of Russian koumiss I have no personal experience.

There are five mulleins all belonging to the natural order of Scrophularaceæ, but the one to which I refer is the great mullein, the *Verbascum Thapsus* of the botanist, and the cuineal mhuire‡ of the ancient Irish medical writers who make frequent allusion to it in the MSS. in our Irish collections. It is delineated in plate 1437, vol. vi. of Sowerby's 'British Botany,' and in the same volume, page 110, it is stated that the great mullein "is rather sparingly distributed over England and the south of Scotland." In Ireland it has been always carefully cultivated, and in many places upon a very large scale, in obedience to a steady demand by phthisical sufferers. It is on sale in most of the medical establishments in Dublin and throughout Ireland, and it is seldom that you will find an Irish newspaper in whose advertizing columns it is not offered. Still it is not in the Pharmacopœia, nor was it formally recognized by the medical profession until the present year; the only officinal prepa-

* *British Medical Journal*, January 27, February 10 and 24, and March 3, 1883; *Medical Record*, March, 1883; *Therapeutic Gazette*, March, 1883; *Australian Medical Journal*, April 1883; *Medical Press and Circular*, February 7, 1883.

† For an interesting account of this cure see the treatise by Dr. G. Carrick. Blackwood and Sons, London, 1881.

‡ The Irish name of mullein means a remedy good for asthma or cough; for it is a curious circumstance that pulmonary consumption appears to have been almost unknown among the aboriginal Irish. Alone in Western Europe, Ireland, on account of its remote situation, did not become a part of the Roman Empire; a circumstance to be regretted, inasmuch as it deprived her of the benefits of Roman civilization, which has everywhere it reached left enduring landmarks. The Roman military authorities contemplated the conquest of Ireland, and were actually preparing one legion for the purpose when the appearance of barbarians on their eastern frontier caused the Imperial government to concentrate their troops and withdraw from Britain. Consequently the English invasion of Ireland in the 12th century found the people very much in the same condition that Julius Cæsar found their British congeners — a thinly inhabited country, with scarcely any tillage, and where the population passed their lives almost entirely in the open air, and subsisted on their flocks and herds. Experience has shown that among such a people, as among the Tartars of to-day, pulmonary consumption is almost unknown; and recent German researches explain the reason why. Of course through exposure pulmonary diseases were common enough among the Irish aborigines, and for them the mullein was employed.

rations of it known to me being the fluid extract of the leaves and the same of the root, preparations which I have tried on a large scale and to which I shall presently allude. Dr. John Evans supplies the succus and the fresh leaves.

The mullein is a hardy biennial plant with a thick stock from 18 inches to 4 feet high, with very peculiar large woolly and mucilaginous leaves, and a long flower stalk with ugly yellow and nearly sessile flowers. The leaves are best gathered in the late summer or autumn, from the biennial plant shortly before it flowers. In former times the mullein appears to have been esteemed as a remedy for diarrhœa, and Dioscorides, Culpepper and Gerarde favourably allude to it in this regard.

The old Irish method of administering it was to take 4 ounces of the fresh leaves or a corresponding quantity of the dry and place them in a pint of fresh cow's milk. This was now boiled for ten minutes, strained, a little sugar added, and the mullein milk drunk while still warm. This dose is soothing and grateful to the præcordia, and phthisical sufferers like it, and experience a want when it is withheld. The superiority of the fresh leaves is very marked; and the dose ought to be taken twice or three times a day. When the leaves are not available the next best resource is the juice fortified with a little spirit or glycerine or fluid extract of the leaves. The fluid extract of the root yields good results, but I prefer the other. The taste of the succus verbasci or of either of the extracts is *per se* disagreeable; but can be completely masked by the addition of some Guinness's porter, which acts as a slight adjuvant, and forms an agreeable mixture. The best method of all is the fresh leaves boiled in milk; but sometimes in advanced cases with delicate stomachs so much milk decoction is found to be heavy. In that event it is necessary to first peptonize the milk with pancreatic fluid and to add a pinch of sodium bicarbonate. The mullein decoction made with peptonized milk digests at once, and the slight bitterness of the peptone is completely covered by the taste of the mullein. In advanced cases of consumption the mullein, although powerless to cure, relieves the cough and diarrhœa, and thus leaves the stomach free for nourishment; in fact it is itself looked upon by the patient more as a food than as a medicine.

Mullein is one of the herbs which I have ensilaged, and I trust by that means to keep it fresh and fit for the milk decoction all the year round. I may here allude to a remotely possible source of risk connected with it on account of the resemblance of very young mullein leaves to young leaves of foxglove. I know an instance in which a gardener during the present season actually transplanted a very young plant of foxglove into a mullein bed. Of course later on this resemblance would not deceive the most inexperienced.

The PRESIDENT having moved a vote of thanks to Dr. Quinlan,

Mr. HOLMES asked whether the specimen of the plant exhibited was the same as was used in the experiments described, because it appeared to him not to be *Verbascum Thapsus*, which had a much more woolly surface.

Dr. QUINLAN said that the plant was usually more woolly; the specimen was, however, the *Verbascum Thapsus*.

Mr. CONROY asked if the cultivated plant was equal to the wild plant in its medicinal properties, for many plants lost in therapeutical value by cultivation. He should also like to ask whether the Doctor had satisfied himself that the beneficial results were attributable to the mullein, and not to the milk in which it was taken or the stout which followed it.

Mr. H. WYATT said this plant, though comparatively little known in the north of England, was much valued in some parts of the Midland Counties as a horse and cattle medicine and particularly in Ireland. A great portion of the working population of Bootle came from Ireland, and it was from them he first heard of it being used as a domestic remedy in consumption. When it was known he had some in his garden, the out-patients of the Bootle hospital frequently asked him for it, and it was in his capacity as dispenser to that institution that he witnessed the beneficial effects and became acquainted with the peculiar method of preparing it with milk, the only way by which the nauseous taste is masked. He did not think there was much doubt about the specimen exhibited being the real plant as it corresponded very well with five plants he had, making allowance for the difference which he found cultivation made in the margin of the leaf. His first plant came up spontaneously and it seemed identical with specimens he had since obtained from Warwickshire. His old Irish gardener never would admit the plant was ugly, and once remarked to him, "Sure it's not such an ugly plant; for there's one bright baby always at the top of it;" referring to a peculiarity in its mode of flowering; it always had a bright ring of flowers round the top of the spike.

Mr. BORLAND said it was hardly correct to say that this plant had only lately come into use medicinally, for he found it was used for almost all the ailments to which Dr. Quinlan referred as far back as 1753, and was mentioned in an old dispensatory written by Dr. James at that date. It was not, of course, recommended as a substitute for cod liver oil, that not being known.

Mr. WILLMOTT hoped Dr. Quinlan would state the source from which these plants could best be obtained.

Mr. ATKINS asked if the plant was popularly used in Ireland for pulmonary diseases.

Dr. QUINLAN said it was, and was curative in the earlier stages and palliative in the later. The objection raised by Mr. Conroy that the beneficial effects noticed might be due to the milk or the stout was one which had been mentioned again and again, but he had been able to bring forward a number of experiments showing that where the milk or stout was administered without mullein, there was no such weight-increasing power shown; he could not, however, here go at length into that question which was really a medical one. He agreed with Mr. Borland that this plant had been used long ago, for it was mentioned by Culpepper, Gerarde, and other writers; but it had died out, and the profession had ceased to employ it, and its use was only kept up amongst the Irish humbler classes. Whether the wild or cultivated plant was the better, he could not say positively, but as far as he could judge they were equally good. The demand in Ireland was so great that the supply of wild plants was not sufficient to meet it, and it was cultivated on a very large scale. It fetched a good price, 2*d.* or 3*d.* per plant. As to the mode of using it, the only really good preparation was the one he had mentioned, boiling it in milk; when boiled in water it would no doubt be equally useful, but its taste would be so nauseous that it would not be readily taken.

The Conference then adjourned.

On Wednesday morning, the Conference re-assembled at half-past ten.

THE LATE MR. ATHERTON.

The PRESIDENT said he had just received an intimation of the decease of an old friend of the Conference, one of its earliest supporters—a man who was local secretary of the third meeting, at Nottingham, and one who by his tact and energy did much towards the success of the meeting, and towards floating the then young Pharmaceutical Conference. It was mainly to his powers of organization that the first Annual Exhibition of Pharmaceutical Appliances was held in connection with the Conference. He was sure every member of the Conference would join with him in deep regret at the loss of John Henry Atherton.

A paper was then read, entitled—

Additional Notes on the Bitter Principle of Hymenodictyon Excelsum.

BY W. A. H. NAYLOR, F.C.S.

In a paper read at an evening meeting of the Pharmaceutical Society in April last, I had the honour of presenting a preliminary account of an inquiry undertaken with the object of ascertaining the nature of the bitter principle of the dried bark of *Hymenodictyon excelsum.* In this communication were embodied results which show that the investigation was pursued to an extent which led to the discovery of an alkaloidal substance, the existence of which was deemed to supply an unequivocal answer to the question at issue. It also contained by inference the affirmation that the bitterness of this particular bark was not due to æsculin, or to its decomposition product, æsculetin, as alleged by Broughton, who had previously examined it. Further, it gave a description of its general properties and its behaviour towards certain reagents. In addition, such data were supplied as it was thought might afford an insight into its constitution. The conclusion arrived at was to the effect that it bore a relation to either beberine or the amorphous alkaloid of cinchona or paricine, by comparison among which the last enjoyed the largest degree of favour.

And now having hastily glanced at the facts hitherto obtained, it may be permitted me to remark that in fulfilment of a promise made at the time of these results, I have meanwhile more completely investigated the subject, and these additional notes are submitted as a sensible advance upon our knowledge of the bitter and probably active principle or principles of this valuable drug.

Method of Extracting the Alkaloid.—Three methods were experimented with for extracting the alkaloid. The first differed only from that previously employed in respect of the process used for purifying the crude base. This consisted essentially in mixing the finely powdered bark with one-fourth of its weight of lime and converting into a thick paste with water. The mixture was dried and exhausted with 90 per cent. of alcohol. The percolate was acidified with dilute sulphuric acid, the alcohol recovered by distillation, and the residue treated with hot water. From experiments with this solution it was found that the addition of carbonate of ammonium caused a black precipitate, which was assumed to be a decomposition product. After filtration caustic soda was added, when a feebly coloured gelatinous precipitate fell. The whole of the remaining solution was similarly treated. The crude alkaloid from caustic soda was dissolved in ether and the ethereal solution poured into large quantities of light petroleum spirit and allowed to stand. By this treatment reddish flocks at first separated out, which subsequently agglomerated and deposited. The alkaloid was recovered by distillation, redissolved in dilute sulphuric acid and reprecipitated with caustic soda, and purified by solution in ether.

The second method was more simple and consisted in exhausting with chloroform the mixture of lime and bark dried at a low temperature and withdrawing the alkaloid from solution by agitation with weak sulphuric acid. From this acid solution the alkaloid was separated by caustic soda. To obtain it in a state of purity it was only necessary after washing it thoroughly to take it up in ether, evaporate, and subject the residue once more to the same operation.

The third method contemplated the extraction of the alkaloid by the use of oxalic solution, but from the difficulty experienced in effecting a complete removal of the colouring matter from the product the process was abandoned. In instituting a comparison of the respective merits of the three methods, the second deserves the preference when adjudged on the basis of purity of product rather than that of quantity in regard to yield.

Description of the Alkaloid.—In the moist condition, as obtained by precipitation with caustic alkali, it is a gelatinous mass of a cream colour and greedy of water, which it retains with extreme tenacity. By exposure it shortly acquires a decided yellow colour, which deepens with increase of temperature and passes into a light brown at 100° C. It has a persistently bitter taste, which is more quickly perceived when in solution than when in the solid state. It is readily soluble in alcohol. ether, chloroform, benzol, and light petroleum spirit, On evaporation of its ethereal solution at a slightly elevated temperature it separates out in the form of oily drops. If the heat be continued beyond that required for the complete evaporation of the ether, the oily drops coalesce and the whole assumes the character of a soft sticky resin. It commences to fuse at 66° C., and at 70° C. it will flow with ease sufficient to admit of its transference to another vessel. It neutralizes acids completely and the solutions are not fluorescent. It refuses to yield crystallizable salts with nitric, hydrochloric, acetic, sulphuric, phosphoric and hydrobromic acids. Its solution in hydrochloric acid is precipitated by nitric acid, sodium nitrate and phosphate, potassium iodide, ferro- and ferridcyanide and bichromate, and mercuric chloride, in addition to the usual alkaloidal reagents. Potassium sulphocyanide added in excess to a neutral solution of the base in acetic acid gives reddish-yellow oily drops. A feebly acid solution gives with bromine a bright yellow precipitate and with solution of chlorinated lime a white precipitate unaffected by ammonia. A two per cent. solution in 90 per cent. alcohol is optically inactive.

Composition of the Alkaloid.—For determining the composition of the alkaloid two series of combustions were made. The one from the base obtained by the lime process, the other from the products resulting from the chloroformic extraction. It was first of all ascertained that the alkaloid suffered no loss between 100° and 110° C. This was regarded as trustworthy evidence that it became anhydrous above 100° C., and in more than one instance its combustion afforded satisfactory proof of its stability at 110° C. It may be stated that in every case the body was burnt with cupric oxide in presence of metallic copper in a stream of oxygen. The products obtained by the lime process (1) and by chloroformic extraction (2) respectively after purification by æther gave as a mean the following numbers:—

	(1.)	(2.)
Carbon	77·02	77·45
Hydrogen	11·02	10·82

As the products by chloroformic extraction (2) gave a slightly higher percentage of carbon, its nitrogen was alone estimated. Two determinations were made by the method of measurement. In one experiment ·364 gram of alkaloid gave 34·2 c.c. of gas, which when corrected for temperature pressure and tension of aqueous vapour was found to be equivalent to 11·32 per cent. of nitrogen. The platinum compound was next prepared and examined. To a solution of the purified alkaloid in hydrochloric acid perchloride of platinum was added to complete precipitation. The double compound was thoroughly washed with warm water and dried at 105° C. When moist it was yellow, when dry reddish-yellow. It was appreciably soluble in boiling water from which it separated on cooling in a granular condition. On ignition it left 25·27 per cent. of platinum. A determination of its chlorine yielded 27·70 per cent. From these results the following formula has been deduced for the alkaloid, $C_{24}H_{40}N_3$. For the purpose of ready comparison the results obtained are placed by the side of those theoretically yielded by this formula.

	Found.	$C_{24}H_{40}N_3$.
Carbon	77·45	77·83
Hydrogen	10·92	10·81
Nitrogen	11·32	11·35
Pt. compound . . .	25·27 pt.	25·24 pt.
Cl in pt. compound .	27·70	27·22

The platinum salt will therefore have the formula $C_{24}H_{40}N_3.2HClPtCl_4$.

For the alkaloid I propose the name "hymenodictyonine." Its main peculiarity is the absence of oxygen in its constitution, and thereby it adds one more to a numerically small class whose natural bases are, perhaps with one exception, volatile.

The salts of the hydrochlorate and nitrate have been prepared, and their study has already commenced.

The determination of their composition and that of certain derivatives of the alkaloid are engaging my attention, and I hope shortly to be able to publish an account of them. It is also extremely desirable that the physiological action of the alkaloid should be put to the test. In regard to this point it may be recorded that a gentleman having incidentally tasted a little of the alkaloid equal in size to a pin's head, experienced flushing of the face followed by giddiness and frontal headache.

In addition to the alkaloid an indifferent principle has been obtained from the bark. It was associated with the first precipitate of crude alkaloid produced by the caustic soda in the lime process. It was observed from its remaining insoluble when the alkaloid was treated with strong alcohol or ether. Repeated boiling with alcohol left it almost colourless. It then presented the appearance of tannic acid. A microscopical examination showed it to consist of micaceous scales. It has a pure bitter taste, quite distinct in character from the bitter of the alkaloid. It is sensibly soluble in hot alcohol but not in ether or chloroform, and is readily dissolved by dilute acids, from which it is precipitated by caustic alkalies. In reaction it is neutral. Nitrogen does not enter into its constitution. It appears to be a neutral principle, and possibly may be a decomposition product of a glucoside. It was dried at 105° and burnt, when it gave the following numbers, which closely correspond to the formula $C_{25}H_{49}O_7$:—

	Found. (1).	Found. (2).	Theory. ($C_{25}H_{49}O_7$).
Carbon . . .	65·00	64·84	65·07
Hydrogen . .	10·76	10·50	10·62.

Whether this body be an educt or a product cannot at present be definitely asserted, and until this point has been ascertained it has been thought advisable not to designate it by any particular name.

The conclusion to be drawn from these results appears to be that the bitterness of the dried bark of *Hymenodictyon excelsum* is due in part, if not in the main, to the existence of an alkaloid whose composition is represented by the empirical formula $C_{24}H_{40}N_3$. In part too its bitterness may be due to the neutral principle having the composition $C_{25}H_{49}O_7$, or to a substance of which it may be a product of decomposition.

There now remains to me the pleasing duty of acknowledging the assistance which my friend Mr. T. G. Nicholson has rendered me in the prosecution of this investigation.

The President proposed a vote of thanks to Mr. Naylor. He thought his expectation that he had made a distinct advance in the knowledge respecting the bitter and probably active principles of this drug was thoroughly well founded. It was to be regretted that, as he stated, the salts refused to crystallize, but it was to be hoped that they would reconsider their decision and succumb to the irresistible coaxing of Mr. Naylor at some future time.

The vote of thanks having been passed—

Mr. Dott inquired if Mr. Naylor considered the formulas he had given for the alkaloidal and neutral principles were probable, seeing they both contained an uneven number of perissad atoms.

Mr. Williams wished to ask Mr. Naylor if he analysed the volatile alkaloids as well as the solid, and found the numbers the same in both cases, because as he distilled it with caustic potash he should imagine that the product of distillation of the solid alkaloids in the presence of caustic potash would probably be very different from the body he started with.

Mr. Holmes asked whether the results obtained by Mr. Naylor threw any light on the constitution of quinine. This plant belonged to the same natural order as the cinchonas. Mr. Naylor mentioned some decomposition products having a peculiar odour, and it might be possible that some of these products might have a similar character to some of the decomposition products of quinine.

Mr. Moss asked if Mr. Naylor had examined the neutral principle of *Hymenodictyon excelsum*, with a view to ascertain whether it was a glucoside or not. With regard to the uneven numbers in these formulas, he apprehended they were merely empirical formulas, and did not profess in any way to give the exact constitution of the bodies referred to.

Mr. Naylor, in reply, said Mr. Moss had anticipated his reply to Mr. Dott. He regarded these as probable formulas, but they were only empirical. The derivatives of the alkaloid had yet to be carefully studied, when possibly they might be able to arrive at the constitutional formula. With regard to the other point, namely, the neutral principle, it was quite possible it might be a decomposition product of some glucoside, and he thought it highly probable, but that was a point which still remained to be cleared up. He was careful not to state in his paper that the alkaloid was volatile, because he was not quite certain as yet whether the volatile portion was a decomposition product or whether it was actually the alkaloid itself.

Can the Law Regulating the Sale of Poisons be amended so as more effectually to prevent their Employment for Criminal Purposes?

BY G. LATHOM BROWNE.

(*Abstract.*)

The inefficiency of the existing legislation has long been recognized by lawyers and medical men, and especially by the Council of the Pharmaceutical Society, which for some years has directed its attention to its amendment. As the result of their deliberations they have in the present year submitted to the Privy Council a draft Bill for the amendment of the Pharmacy Acts, which may, if treated by an experienced draftsman, in all probability form the basis to new legislation. As it proposes to cover the whole question of the sale of drugs, I have in the course of these notes only referred to those suggestions in it which more especially refer to the sale of poisons.

Cotemporaneously with this movement in England, *projets de loi* dealing with the practice of pharmacy in the French Republic have been introduced in its Legislative Assembly, and referred to a Commission, which has lately presented an exhaustive report on the whole subject, and agreed on certain propositions which will form the basis of a Bill in place of the two *projets* previously submitted to the Assembly. To such of its recommendations as affect the sale of poisons I have referred in these notes. A sketch of its general provisions was given in an article in the *Pharmaceutical Journal* of July 14, 1883.

The sale of poisons is at present regulated by the following statutes:—

(1) Arsenic and its acids and other colourless preparations of arsenic.

By the 14th Vict. cap. 13, 1852, "all persons selling arsenic are ordered to keep a book, in a prescribed form, stating the date of sale, the name, place of abode, condition or occupation, of the purchaser, the quantity sold, and the purpose for which it is required. To every such entry the signature of the purchaser, and of his referee and of the seller are to be affixed, and no arsenic is to be sold to anyone unknown to the seller, except in the presence of some witness known to him, and who also knows the purchaser. Nor is any arsenic to be sold to any one under age."

It is also provided by the same statute that, "before the sale, arsenic shall be mixed with soot or indigo in the proportion of 1 ounce of soot or ½ ounce of indigo to 1 pound of arsenic: except in cases where, according to the representation of the purchaser, such mixture would render it unfit for his purpose, when it may be sold without such mixture in quantities of not less than 10 pounds." This Act, however, does not extend to the sale of arsenic by any legal practitioner, nor to its sale by wholesale or retail dealers upon orders in writing.

In the case of the trial of Madeline Smith for the murder of her lover L'Angelier, Edinburgh, 1857, it was stated by Professors Penny and Christison that the indigo, especially when it is waste and not pure indigo, can be removed from the arsenic by dexterous manipulation.*

In the same case it was admitted by the storekeeper of a firm of printers and dyers in Glasgow, that they "purchased arsenic in quantities of from three to four hundredweight at a time in its pure state, which was put into store among other things quite open—that, when any was taken out of the barrels for use, the lid was loosely laid on again—that it was taken from store in open wooden pails, and that the abstraction of an ounce or two would not be missed."

By this statute the sale of arsenic was alone protected; the sale of all other poisons was left entirely unguarded, and the sale of them and of arsenic, subject only to the statutory provisions, was open to the most illiterate.

In consequence of the numerous cases of poisoning by more refined methods, and of deaths arising from the dispensing of poisonous drugs by incompetent persons, the Legislature was induced in 1868 to pass the Pharmacy Act (31 and 32 Vict., cap. 121), by which, and by its Amendment Act in the following session of Parliament, the sale of poisons has hitherto been regulated.

By this statute, whilst the rights of chemists in trade previously to January 1, 1868, were preserved, it is provided that, for the future, it should be "unlawful for any person to sell or keep open shop for retailing, dispensing, or compounding poisons, or to assume the title 'Chemist and Druggist, etc.,' in any part of Great Britain, unless such a person shall be a pharmaceutical chemist, or a chemist and druggist within the meaning of this Act, *and be registered under this Act, and conform to such regulations as to keeping, dispensing, and selling of such poisons as may from time to time be prescribed by the Pharmaceutical Society with the consent of the Privy Council.*" The poisons to be included in the operation of this Act are given in its first schedule. By Section 16 of the Act, however, it was provided that the Act should not extend to any legally qualified apothecary or veterinary surgeon, nor interfere with "*the making or dealing in patent medicines, nor with the business of wholesale dealers supplying poisons in the ordinary course of wholesale dealing.*"

Subject to these provisions, it is further enacted by Section 17 that it should hereafter "be unlawful to sell any poison either by wholesale or retail, unless the box, bottle, vessel, wrapper or cover in which such poison is contained be distinctly labelled with the name of the article and the word 'poison,' and with the name and address of the seller of the poison." And it is enacted that the provisions in the Arsenic Act, before quoted, with reference to its sale to any person, should be extended to the sale of all poisons, stated in the *first part* of the first schedule to the present Act, and to any other poisons that might hereafter be added to it by the Pharmaceutical Society with the consent of the Privy Council. But as in the previous section wholesale dealers in poisons, whether for export or the home trade, are excepted from the precautions provided in the case of poisons in the first part of the Schedule, or of attaching the label with the name and address of the seller, and not any of the provisions of this section are to apply to medicine supplied by legally qualified apothecaries or one registered under this Act, "provided such medicine be labelled in manner aforesaid with the name and address of the seller, and the ingredients thereof entered with the name of the person to whom it is sold or delivered" in a proper book of prescriptions. So far, however, as the sale of arsenic was concerned the provisions of the Arsenic Act, 1852, are preserved intact.

In the next session of Parliament the provisions of this section were relaxed in favour of a legally qualified medical practitioner. By the Pharmacy Amendment Act, 32 and 33 Vict. cap. 117, sec. 3, it was enacted that in the case of a medical man, the entry of the name of the purchaser, the name and quantity of the poison sold, and the purpose for which it was required, and the signature of the purchaser, are not to be required.

How this relaxation of precautions may operate was seen on the late trial of Dr. Lamson for the murder of his nephew. In that case it appeared that the aconitia was sold to him by an assistant in the shop of Messrs. Allen and Hanbury, merely on the faith of the assistant finding the name of Dr. Lamson in the Medical Directory.

"Suppose," said Sir Henry Hawkins to the assistant, "I applied and gave a name out of the Medical Directory, and asked for 2 grains of aconitia, would you sell it to me?"

Answer—"If I were satisfied at the time that you were a medical man I should let you have it."

The Judge—"Then anybody of respectable appearance and well dressed might apply? and is there anything by which you can satisfy yourself that the applicant is not an impostor and telling you what is not true?"

Answer—"The only thing would be the style of writing—whether it was in the style characteristic of a medical man."

The Judge—"That seems hardly satisfactory."

Mr. Poland—"The Act does not require registration in the case of sale to a medical man."

The Judge—"It strikes me that anyone could go, if he had sufficient knowledge to write in the technical style of medical men, and get poison without difficulty; and though the matter is not before us in this case, it may be that the law requires amendment in this particular."*

The jury appended to their verdict a presentment urging greater restrictions on the sale of poisons, with which the judge thoroughly agreed and undertook to forward to the Home Secretary. During the past session of Parliament it was announced that a "New Poisons Act" was preparing—like many other promises it has come to nothing.

The following defects in the existing legislation on the sale of poisonous drugs may be noted:—

(1) The business of the wholesale dealers in poisons in the ordinary case of business is not fettered with any precautions. Hence, especially in the case of arsenic and in its acids so largely used in manufacture, hundredweights are kept in the stores of manufacturers with as little precaution as in the case of most innocuous materials.

* Trials for Murder by Poisoning: Case of Madeline Smith, evidence of Professor Penny and Professor Christison.

* See Report of the trial of Dr. Lamson, 'Trials for Murder by Poisoning,' p. 544-5 note. The difficulty of tracing the purchase of the aconitia to Lamson in this case was increased by the practice of Messrs. Allen and Hanbury's shop only to enter, in cases of purchases by medical men, the amount paid with the letter C against it. Hence a doubt was for a time raised whether it was atropia or aconitia that had been sold. This is apparently the custom with all chemists and druggists.

See the evidence already reported in the case of Madeline Smith. By the Draft Bill of the Pharmaceutical Society, Section 3, it is proposed that a register should be kept by the wholesale seller of the sales of all poisons for twelve calendar months, but no provision is proposed to be made for their safe custody by the purchasers in a locked store, or for their being delivered out only by a responsible person, and being taken thence under proper precautions. Surely these precautions are absolutely necessary.

(2) The exception in favour of medical practitioners from the entry of the sale required in the cases of other persons, is liable to serious abuse, if no other means of identity are used than those of finding the name given by the purchaser in a Medical Directory, or the form in which the purchaser writes the prescription which he tenders to the seller. See the case of the sale of aconitia to Lamson previously reported.

(3) *Vermin Killers.*—Though by the Pharmacy Act, 1868, the sale of such of these compounds as contain strychnia and other poisons, in Part 1, Schedule A., is limited to certified chemists and druggists, and subjected to the same precautions as that of the poisons in the first part of the Schedule, there is no doubt that they are still sold by unqualified persons, especially in poor neighbourhoods and country places. That they are marked with the word "Poison" and with the name and address of the seller is little or no protection. Besides, those vermin killers, in which phosphorus is the active ingredient, are not even required to be labelled "Poison," and yet they are intensely poisonous, and have been made use of, especially in France, for criminal purposes, though less frequently in this country (see the case of Fisher, a girl convicted at the Norwich Autumn Assizes, 1871, of attempting to poison a family by putting phosphoric vermin paste in the teapot). In the case of Silas Barlow, 1878, it was admitted that the vermin killer had been bought of an unqualified person, and the purchaser, though he noticed it was labelled "Poison," had left it openly in the room which at one time the murderer had occupied, and where he had ready access to it.* "If," said Dr. Bernays, "they are used at all, they should never be made or sold except by the legitimate pharmaceutists of the country under proper precautions."

(4) Though by the statutes the keeper of a chemist's shop is made responsible for the sale of any poison in contravention of their provisions, by his servant or apprentice, the actual sale of these drugs by incompetent persons, especially in country shops, is not practically prevented. Hence the frequent cases of errors made in selling poisonous articles in mistake for innocuous medicines, with the most serious results to the purchasers. The sale of drugs by any one but a qualified chemist should be made unlawful, and subject the master to the withdrawal of his licence.

(5) *Patent Medicines.*—These drugs, for internal or external use, the chief characteristic of whose composition is their secresy, and of which the technical names of their ingredients are in most instances suppressed, or concealed by the most fanciful and attractive titles, are the source of almost unlimited danger to the public, as they can now be purchased of various tradesmen, besides chemists and druggists, grocers, oilmen, and especially at co-operative stores. By an Act passed in the year 1783 (23 Geo. 3, cap. 1), a stamp duty for the purposes of revenue was for the first time imposed on these articles, and by a subsequent Act in 1785 (25 Geo. 3, cap. 62, sec. 16), it was further provided that "any person whatsoever, who has or claims to have any secret art or sole right of compounding preparations of drugs and advertising the same as specifics for the cure or relief of any complaint or malady shall fix a Government stamp to the vials, vessels, or inclosures containing them." The object of these Acts was simply the increase of the revenue, and of course in no way warranted the efficacy or the safety of the secret composition. It is impossible, however, for the Government stamp not to be regarded by the ignorant among the public as a warranty of the specific to which it is attached. The result has been a sale of these specifics to a most dangerous extent, no less than *seventeen millions* of patent medicine stamps having been issued in the year 1881, and, apparently, to judge from the amount received from this source, a large number in the past financial year.* Many of these specifics are, no doubt, as harmless as they are useless, but a far greater proportion are composed of the most potent poisons. The newspapers teem with instances of the fatal results of their incautious use, and no wonder. "No word of specification or limitation as to what may or may not form the component parts of these secret mixtures occurs in any Act; no directions or restrictions of labelling are required in order to show the technical name or nature, whether simple or potent, respecting these mysterious compounds. The one requirement is the exhibition of the stamp certifying the Government duty." In the interests of the revenue these dangerous specifics are specially protected by the Act to regulate the Sale of Poisons; the Pharmacy Act, 1868, sec. 16, providing that "Nothing hereinbefore contained shall extend to or interfere with the making or dealing in patent medicines."

The practice of patenting medicines appears to be peculiar to this country; at least, in France, Austria, Belgium and Germany, foods, drinks, medicines, and chemical products cannot be patented. According to the existing law in France the sale of secret remedies is prohibited, and their courts of law have decided that this designation covers any medicine not prepared from the prescription of a medical man, or not contained in the Codex, authorized by the Government after a favourable report from the Academy of Medicine, to which a sample of the composition and prescription of its contents have to be sent for analysis before their sale can be permitted. It appears also from the reports of the Municipal Laboratory of Paris for some ten or twelve months, that no item of patent medicines, proprietary drugs, or secret remedies is to be found in the tabulated lists of samples there analysed and reported upon. And though this restriction is considered by the Commission by which a new Pharmacy Act has been prepared, and which will in all probability be enacted in the next session of the French Legislature, to act as a prohibition of the sale of a large quantity of specialities of known composition, and must operate as a bar to pharmaceutical progress, they do not recommend its relaxation except in the cases of compounds not including certain excepted poisons. They also recommend that even in these cases they should be sold only by pharmaciens and with this precaution, that the labels on them shall bear the names and doses of the active ingredients, and that where an official drug is used, its Codex name shall be given. On the other hand, the Commission are of opinion that all "secret preparations" of undisclosed composition should be strictly prohibited. The suggestion of the free traders in medicines, even to the extent that any pharmacien should be at liberty to sell any medicinal substance, whether poisonous or not, upon the express demand of the buyer, supplemented in the case of a poison by his signature, was rejected.

By the "Draft Bill" of the Council of the Pharmaceu-

* See the case of Silas Barlow, for poisoning his mistress with a vermin killer, in all probability that sold under the name of "Battle," in a threepenny packet of which Dr. Bernays found 10 per cent. of strychnia. In a specimen analysed by Dr. Tidy he found as much as 23 per cent. of strychnia. The vermin killers of Battle, Gibson, Miller, Marsden, Hunter and Barber, all contain strychnia, and legally ought only to be sold under the same restrictions as that poison. To Dr. Bernays's remark Mr. Justice Denman, who tried the case, added, "a very proper suggestion for the consideration of the Legislature."

* The amount received in 1881 was £139,762 18*s.* 10½*d.* and in 1882, £145,266 0*s.* 6*d.*

tical Society, section 4, it is suggested that "it should be unlawful to sell by wholesale or by retail any patent medicine, or any article bearing a patent medicine stamp, being or containing a poison within the meaning of the Pharmacy Act, 1868, unless the box, bottle, package or vessel in which the same is contained, wrapper, if there be only one, or the outermost wrapper, if there be more than one, be labelled with the name and address of the first seller, name of the patent medicine and the word 'Poison.'" By the 9th section it is proposed that the retail of such patent medicines shall be limited to chemists and druggists authorized to retail poisons under the Pharmacy Act of 1868, with this very dangerous exception, that nothing in this section shall extend to or interfere with the wholesale dealing of patent medicines, or with the wholesale dealing with poisons in the ordinary case of wholesale business. By the section previously cited (Sec. 4), however, these patent medicines would have to be labelled with the name and address of the first seller, the name of the medicine, and the word "Poison."

I willingly admit that this is a movement in the right direction, and valuable as far as it goes, but I cannot but think that in dealing with these sources of public danger we might take a leaf out of the book of the Central Sanitary Bureau of Japan, quoted by Mr. Hubbard from the *British Medical Journal* of July 2, 1880, in his valuable article on Patent Medicines before referred to. By the laws of that country, "proprietors of patent medicines are bound to present at the Government laboratory a sample, with the names and proportions of the ingredients, directions for its use, and explanations of its supposed efficacy, before they are allowed to vend them. During the year reported on no fewer than 11,904 applications for licence to prepare and sell 148,904 patent and secret medicines were made. Permission for the preparation and sale of 58,638 different kinds was granted, 9918 were ordered to be discountenanced, and 70,943 remained to be reported on. The majority of those which were authorized to be sold were of no efficacy, and but few were really remedial agents. But the sale of these was not prohibited, as they were not dangerous to the public health."

The disclosure of the compounds of these specifics to an official chemist, under the seal of secresy, ought not to be objected to by any inventor. He must know that he is at the mercy of any qualified analyst, who can, if he cares, discover and disclose his secret, to which the Government stamp is no protection. The results of the analysis of patent medicines are repeatedly being divulged in the public journals and prescriptions published for their composition. To label them with the word "Poison" —to make conspicuous on the label the technical names of their ingredients—the full limit of a safe dose—and to confine the sale of them to qualified chemists, and to subject their sale to the same precautions as to registry as other poisons, may do much good. Far better would it be if the Government were empowered to refuse the stamp (which it is impossible to prevent being regarded as a warranty) to all inventors who are not willing to submit their compounds to an official analyst. The miserable sum of £150,000, out of eighty-eight millions of our taxation—thus obtained at the risk of the public health—is not to be thought of for a moment. Far better would it be to abolish the stamp altogether, than, for the sake of such a paltry revenue, to continue so dangerous a source of deception.

In suggesting these further restrictions on the sale of poisonous drugs and of those secret remedies so popular as patent medicines, I have endeavoured to avoid unnecessary interference with legitimate trade, and yet to secure some additional protection to the public. The legitimate requirements of trade demand consideration, but the protection of the public is of paramount consideration. No legislation will prevent poisoning; all that can be done by it, is to make poisoning more difficult and its detection more easy. Among many suggestions on this subject, that of defining by statute the maximum quantity that may be safely sold of any poison to one purchaser, has been suggested. That such a restriction might be beneficial in checking accidental poisoning I allow. I do not, however, see its value in the case of the criminal poisoner, who could evade it by purchasing another and another dose of different chemists. Palmer did not purchase the strychnia of only one chemist: Madeline Smith purchased the arsenic at different shops, and Lamson did the same with aconitia. Besides, if the quantity to be sold at one time and to one purchaser is to be limited to a medicinal and not fatal dose, who shall decide what that is? How the most eminent medical authorities differ on this point was forcibly shown in Palmer's case, and it must be admitted that it varies with the condition and constitution of the person to whom it is administered.

With these concluding remarks, I offer the preceding suggestions as a contribution to the amendment of the existing law by which the sale of poison in this country is regulated.

The following is the discussion that followed the reading of this paper, and that by Dr. Tidy, on the same subject, which was printed in last week's number (page 294):—

Mr. H. Bendelack Hewetson, Leeds, said that he spoke with some amount of diffidence in the presence of such celebrated authorities, but it was a principle incumbent upon every medical man to bring forward the conclusions to which he had been driven by experience in his practice, especially in relation to such a subject as the sale of poisons. Dr. Tidy had alluded to the danger of dispensing liniments and lotions in bottles of the ordinary type. An instance of that had occurred quite recently to himself. He had been sent for in a great hurry to a patient who was said to be dying. He had, on the previous night, given the patient, who was suffering from rheumatism, an ordinary sedative draught together with a liniment for application to the affected joint. The first night he had taken the draught properly out of the medicine bottle, but, on the second night, the nurse, having been ordered to repeat the dose, had deliberately given the patient two ounces of belladonna liniment, which was, of course, a deadly poison. The draught and the liniment had been dispensed in precisely the same kind of bottle, and thus the ignorant nurse had easily been led to mistake the one for the other. The patient was absolutely unconscious for seven hours, but, by careful treatment, was restored. The question of drugs sold by quacks under the pleasing names of soothing syrups, mother's rest and so on, was a very important one. A short time ago a little child was brought to him at one of the infirmaries suffering from an affection of the eyes. The child presented symptoms of narcotic poisoning, and the evasive answers to his questions which were made by the person who brought the child confirmed his suspicions in that respect. He ordered the child into the hospital, and, within eight hours, it died. Although the coroner's inquest distinctly showed that the child had died from the effect of repeated small doses of narcotic poison, it was impossible to fix responsibility upon anyone. The child was one for whose parents it was convenient that it should be got out of the way. There was a wholesale system of killing young children by means of these quack medicines going on at the present day, and, although it was impossible by strict legislation to prevent it, there clearly ought to be some amount of restriction put upon their sale. A certain degree of restriction ought also to be placed upon the wholesale sale of poisons for manufacturing purposes. The daily association with poisons, especially those used in the manufacture of dyes, if it did not actually threaten the lives of the workmen so employed, certainly produced very marked phases of ill health.

Dr. Richard Smith said the most noticeable suggestion in Dr. Tidy's paper was the abolition of the Schedule of Poisons and the substitution for it of a definition of the word "poison," which should be accurate and comprehensive. If that were done the difficulty would arise when the article was purchased as to whether it was for internal or external use. The same thing at one time might be a dye and at another time might be a poison. Magenta, for instance, and in fact all the anilines were essentially poisons if regarded from the point of view of internal use. Many of them indeed had a very mischievous effect when used upon clothing worn next to the skin. It was impossible in any Act which might be passed to regulate the sale of poisons to distinguish in every case between those substances which were used in the ordinary arts of life, and those which were to be taken medicinally or might be used criminally for the destruction of life. But if the schedule were done away with that difficulty would be increased tenfold. The present schedule was not perfect; in fact, it was weak from every point of view. Still, if it were done away with, in addition to the above, there would arise another difficulty, namely, that the chemist would be left to form his own judgment in each particular case as to what was or was not a poison. It might happen that on one side of the street a substance would be called a poison, and the purchaser of it asked for his name and address and subjected to other inquiries, while on the other side of the street it would be sold without any difficulty whatever. For instance, oxalic acid, though a deadly poison, was frequently used for cleaning brass and other like domestic purposes. The shop at which that article was sold with the least trouble and the fewest inquiries would come to be the most popular in the neighbourhood, not only amongst those who desire to purchase drugs for criminal purposes but amongst perfectly well meaning persons. The competition of trade would thus lead the chemist to take as loose a view as possible of the meaning of the word "poison." Especially would that danger arise in the case of substances not poisonous in small doses. If the schedule were done away with the consequence would be that by buying small quantities, and buying them repeatedly, a person might altogether escape questioning except in the case of the very strongest drugs. That point, therefore, would require reconsideration before it could be with advantage incorporated in an Act of Parliament. He quite agreed with the suggestion that in any future legislation upon the subject it would be incumbent upon medical practitioners and veterinary surgeons to submit to some restrictions, and he would even make such restrictions more severe than Dr. Tidy had suggested. Although the majority of general practitioners who did their own dispensing were exceedingly careful, there were instances, and those not rare, where such dispensing was done in the most careless manner that could be conceived. There were cases where servant girls and grooms had been set to make up medicines, and they had had at their command poisons of the most deadly character, together with the Epsom salts which formed the greater proportion of the medicine given to the poorer class of patients. It might be a strong measure, but it was eminently desirable that in all cases where a prescription contained an acute, or to use a term which had been found fault with, a deadly poison, it should be compulsory upon the medical practitioner to have it made up by a registered pharmacist. Such a course would only be carrying out what was the general custom of the higher branches of the profession; it would not be a serious financial injury to the general practitioner, while it would certainly give a little additional security to the public. There was a great deal to be done with regard to the question of patent medicines, which had been alluded to more particularly in Mr. Lathom Browne's paper. It was much to be desired that every so-called patent medicine should be really patent. It ought to be incumbent upon every person who put forward a specific to state distinctly, under a penalty for mis-statement, any powerful ingredient which was contained in that specific. In some cases this was done by the proprietors of so-called patent medicines. If such medicines were really patent, that was laid open to the world, so that medical men might know their constituents, and the public generally be aware of what they were taking, there would be little risk arise, at all events, of acidental poisoning. The public would be on their guard, and consequently the mischief would not be done. At present the public had no means of discriminating between a number of simple, perhaps harmless, remedies of the type of Cockle's pills and others—he did not wish to advertise them by mentioning their names—and those which contained positively dangerous ingredients, such as mercury and other deleterious substances. The real point to be aimed at in the improvement of the law was not the abolition, but the careful amendment of the schedules to the Act relating to the sale of poisons. Provision ought to be made for the proper keeping of drugs and poisons in the hands of those entitled to deal in them, and also for the publication of the constituents of so-called specific remedies. The sale of such specifics, as well as of poisons, ought to be confined entirely to pharmaceutical chemists or persons properly qualified to deal in them.

Mr. Michael Carteighe, President of the Pharmaceutical Society of Great Britain, said that he ventured to take upon himself the responsibility of criticizing the two papers read, especially the one by Dr. Tidy, as it was important that the latter gentleman should be corrected on one or two points. Dr. Tidy had been using vigorous language all round, in which, from the point of view of the medical jurisconsult, he was perfectly justified. Dr. Tidy's experience in cases of criminal poisoning was very great, perhaps greater than that of any other living expert, but that gentleman would pardon him for saying that he had treated the subject rather from the point of view of the Public Prosecutor and toxicologist than from that of practical everyday experience. Poisons were used for so large a number of purposes of a legitimate character that it was quite obvious to any thinking person that it would be impossible to insure perfect safety in regard to the sale of them. In England the use of poisons for manufacturing purposes was greater than in any other country. Dr. Tidy's remarks with reference to the question of what was a poison and what was innocuous would be extremely valuable to lawyers, and everything that he said upon that score appeared to be incontrovertible; but, on the other hand, Dr. Tidy had lost sight of the lines upon which legislation had hitherto been conducted in this country. By the advice, not only of the Pharmaceutical Society, but also of the medical advisers to the Government, the principle had been accepted in connection with legislation upon this subject that it was impossible to prevent criminal poisoning, just as it was impossible to prevent one man getting a pistol and shooting another. In most if not all cases in which the law was supposed to have broken down, crime could not have been prevented had the law been stricter. At the same time the law ought to provide every facility for bringing offenders, whether medical men or otherwise, to justice. With regard to accidental poisoning the principle was different. He personally had had something to do with drafting the existing Act relating to the sale of poisons. That Act had been somewhat maligned, and no doubt it was a little difficult to understand in certain cases; but the principle of the Act was essentially this: that accidental poisoning could be prevented, and a certain amount of security given against criminal poisoning, by registration and other means. Despite everything that Dr. Tidy had said, the chief security in his judgment was to be found in the intelligence of the person who sold the poison. What was the use of making laws to become a dead letter? It was admitted that the existing law was not carried out; he, for his part, was aware that in some districts it was not, and yet Dr. Tidy was asking for further restrictions. To a certain extent, he agreed with him, but they must be careful not to draw the rope of legislation too tight lest it break. The two cardinal points to be kept in view were the proper training and qualification of the seller, and the inditing, labelling, or doing of something at the time of sale which should also afford additional security to the purchaser. It was perfectly obvious that when persons were on the register, and had had some fair amount of training and education, their whole livelihood depended upon their exercising care in the practice of their profession. No doubt there had been rare cases, such as that mentioned by Mr. Hewetson, where druggists were a little to blame in sending out lotions and liniments in bottles similar to those containing draughts, but such cases were much less common than formerly. That was attributable to the better education of pharmacists as a class, and the greater responsibilities attaching to them. If a man was found to have committed a mistake of the kind referred to his business was at stake. It was not a mere question of a fine; if the public had its confidence in him shaken the consequences were much more serious than would be represented by any fine which might be imposed upon him by Act of Parliament. Mr. Lathom Browne had in his paper mentioned that the French were disposed to relax the severity of the restrictions which are now placed upon the sale of poisons in that country. The French law was at the present time very much what Dr. Tidy would make it in England; but, from his (Mr. Carteighe's) inquiries amongst French pharmaciens and others, he found, as he expected to find, that practically it was evaded with the tacit consent of both buyer and seller, because it was impossible to carry it out. There were legitimate uses for poisons, and therefore there must be places where such poisons could be bought and sold. There was no way of affording the public the complete protection it required other than by restricting the sale of a large number of drugs which were not statutory poisons, but which were very potent and very mischievous, to qualified persons. That constituted the real difficulty. When the present Act was passed, the Pharmaceutical Society would have, with the concurrence of the Government, increased the Schedule by including in it many drugs very potent and capable of doing almost as much mischief as those now classed poisons. But they were prevented by free trade doctrines, and the sale of poisons for use in manufactories was so gigantic that the Society found it impossible to go further at that time. The Pharmaceutical Society, therefore, might claim credit for itself that it was sufficiently public spirited to insert in the Schedule the minimum only of articles, because the practical effect of including the others would have been to limit their sale to persons registered under the Pharmacy Act. At the same time it was undoubted that the only complete safeguard for the public would be to place restrictions upon the sale of all potent drugs. Dr. Tidy criticized the Act, and asked, amongst other questions, why there were two schedules. He would give one reason. Take the case of such a thing as red precipitate. It was a domestic remedy. It might be a very undesirable thing that it should be a domestic remedy, but the fact remained that it was. No mother would consent to the sale of it being restricted to the ordering by a prescription. Doubtless it would be a much better thing not to use domestic remedies, but to call in a medical man. Still the system had grown up, and though it was becoming less common, yet there was an enormous amount of domestic doctoring, and while it existed a certain amount of latitude must be allowed. The use of these things was perfectly well understood by the public. Moreover, red and white precipitate were substances not easily swallowed accidentally. They had a distinctive character about them, and would be properly labelled, and to ask that they should be sold under the same restrictions as applied in the case of, say, strychnia, was to ask for what would be impossible in practice, though possibly logical in principle. Speaking from statistics he was able to say that in certain poor districts in London such articles were sold to as many as a hundred persons on a Saturday for use in domestic medicine. He doubted whether it would be possible to register every sale, or whether any additional security would be afforded by so doing. Every person who purchased red or white precipitate knew how to use it, and was familiar with its dangers. In such a case he ought to be allowed to purchase it with less difficulty than a poison like strychnia. With regard to cantharides, that was used for a specific unlawful purpose and its being placed in Part I. of the Schedule was, so to speak, a piece of preventive medicine. Dr. Tidy was also very satirical about preparations of prussic acid being called a poison; but, as a chemist, he must be perfectly familiar with the fact that medicinal prussic acid was a preparation containing only 2 per cent. of real prussic acid. The sense in which the word "preparations" was used in the Schedule was perfectly well understood by medical men and pharmacists, and the Pharmacopœia was the authority for its introduction. In that work salts of morphia were not classed as preparations of opium. With regard to the vexed question of poison bottles, there was one serious objection to a special kind of bottle. It was this. With the better class of people there was not so much difficulty in getting a special bottle used for the purpose intended. But with others it was found that they declined to throw away the special bottles, and hence the latter, when emptied of their original contents, were filled with harmless domestic liquids, even though the word "poison" formed part of the bottle. It would be impossible to compel people to take the bottles back to the chemist after they had done with them and, consequently, the difficulty he had mentioned was a serious one. With regard to wholesale dealing it would be seen from the paper of Mr. Latham Browne that the Pharmaceutical Society had, at the suggestion of the Government, prepared a clause dealing with it. It was impracticable to deal with it in the way Mr. Lathom Browne suggested. We did not hear much of accidental poisoning from arsenic in places where arsenic was used for manufacturing purposes; nor of poisoning from oxalic acid in places where the latter was largely used in the manufacture of straw hats and bonnets. Of course there might be cases of criminal poisoning, where one workman, knowing the nature of the substance, used it feloniously; but it would not be logical to fetter an entire industry on that account. Dr. Tidy's remarks with reference to the regulations were not quite correct. What was done by the members of the Pharmaceutical Society was this. A series of suggestions were adopted in the form of recommendations, which were printed and sent out to every registered chemist and druggist. He did not wish to say anything about the wisdom of such a step, but that was what was done, and it had been productive of a great deal of good, though those recommendations had not the force of law.

Dr. Tidy: Was not the Council turned out because it proposed these regulations?

Mr. Carteighe said that the printed recommendations had been sent out to every chemist and druggist and a certain amount of good had arisen from them. One of the objections raised to them was that it seemed a little unfair to ask pharmacists to adopt what many of them thought troublesome precautions, while the great mass of cases of accidental poisoning occurred in workhouse infirmaries, hospital dispensaries, and in the surgeries of medical men, the dispensers in which were not to be subjected to those regulations. He cordially agreed with Mr. Smith that it would greatly conduce to the safety of the public if every medical man would discontinue the practice of dispensing medicines. He thought medical men would be willing to do that as pharmacists became better educated. The public also as it became better educated would understand and appreciate the advantages and security of this system, which was in vogue all over the Continent.

Dr. Tidy said that as a medical man he was very glad to second the last remark which Mr. Carteighe had made as a pharmacist. He hoped the day would come when pharmacists and medical men would each attend only to their respective work. With regard to Mr. Carteighe's remark about not drawing the rope too tight, no one felt the force of that more than he did, and he hoped he had made that perfectly clear in his paper. At the same time it was necessary to draw the rope just tight enough. Mr. Carteighe had remarked upon the improved education of pharmacists, and it was certainly the fact that the present race of pharmacists was very different from the past. That was one of the reasons why the question as to what was or was not a poison might be very fairly left to the improved education of the pharmacist instead of drawing up a schedule which fettered him in the way that the present Schedule did by compelling him to include certain things which were perfectly useless, and leaving out other things which it was of the utmost importance should be included. He could assure Mr. Carteighe, as head of the Pharmaceutical Society, that there was no feeling of opposition to pharmacists in anything he said. On the contrary no one was more conscious of what the Pharmaceutical Society had done to raise the education of chemists and druggists. But with that improved education they surely might omit the Schedule, and leave it to the judgment of the pharmacist whether to insert the entry of a sale in the poison book or not. He was quite ready to admit that there were very serious objections to omitting the Schedule, but there were also very serious objections to retaining it. In fact it was a balance of difficulties. There was a good deal of point in the remark of Mr. Smith that if the Schedule were abolished the chemist who made the fewest inquiries would attract all the trade away from his more scrupulous rival. He was very much struck by that remark, but, still there were such grievous difficulties involved in the retention of the Schedule, that he would prefer to have it removed, and to trust to the individual judgment of the pharmacist. If the sale of poisons was taken out of the hands of herbalists, quack doctors, grocers and oilmen, and limited to properly qualified persons there might be allowed, within certain limits, such freedom as was consistent with the improved education of pharmacists as a body. He entirely agreed with Mr. Carteighe's remarks concerning accidental poisoning, but still he thought the subject required some regulations, and that it would be well for the Pharmaceutical Society to legislate in such a way as to meet the feelings of the public on the matter.

The Chairman, in closing the discussion, said that the storage of poisons in chemists' shops might be improved with advantage, for it had often struck him that poisons were stored in a very careless manner. He had also frequently thought what marvellously clever fellows chemists must be to be able to read doctors' prescriptions without making mistakes, for, as a general rule, the more eminent the physician the worse he wrote. Dr. Tidy's remarks about preparations and tinctures reminded him of his experience in Colorado, in the Rocky Mountains. Colorado was a temperance city, and it was impossible to get any intoxicating drink in the ordinary way. But a man had nothing to do but to go to a chemist's shop and ask for tincture of myrrh and he got what he wanted. There was just a little something put into the alcohol to make it saleable by law. He was very glad to hear that there was such a demand for Epsom Salts, for he possessed a piece of land at Epsom on which he was anxious to build a house, but he had hitherto been deterred from doing so from the fact that there was no water anywhere near it except what was supposed to be impregnated with Epsom salts.

CHEMISTS' ASSISTANTS' ASSOCIATION.

The opening meeting of the seventh session of this Association was held in the rooms, University Chambers, on Wednesday evening, the 10th inst., when the President (Mr. C. Parkinson) delivered an address. There was a large attendance.

The President, after a few preliminary remarks, said that the pharmacist of to-day found himself in the unhappy position of having been educated to perform services for which there is a gradually decreasing demand. For many years past the cry had been "Educate, Educate, Educate!" Education was to be the panacea for all woes; to weed out from the ranks incompetent men, to raise the pharmacist in the estimation of the public, to make him prosperous in life and send him down to the grave full of riches and honour. Unfortunately, this programme had been very imperfectly carried out, and now the cry was "Legislate!" He ventured to assert that the chief aid to pharmacists must come from themselves. The knell of monopoly was being sounded from every platform, and with an extended electorate the chances of legislative redress would become even more slender than they were at present. There could be no doubt but that the great success of the stores was due to the fact that for some years past the depressed state of trade and agriculture had compelled the peer, as well as the peasant, to husband his expenditure, and make money go as far as possible, and while the stores had powerful and influential friends, both in the Legislature and the press, it could hardly be supposed that a blow aimed so manifestly at them would be allowed to pass unchallenged; pharmacists should therefore look to themselves for help, and not be deluded into trusting too much to legislation. After referring to the supply of medicines by herbalists and stores, Mr. Parkinson said another factor in the consideration of this question was the deluge of novel and elegant pharmaceutical preparations, which our American cousins have been showering upon upon us for some time past, and which physicians are not ashamed to prescribe. It was possible almost to count on the fingers the names of the eminent physicians who are contented with the preparations of the pharmacopœia. It was no use shrugging shoulders and calling on Jupiter to shatter the machinations of these wicked men. Pharmacists must make preparations of their own of equal elegance, and bring them before prescribers with equal persistence. Associations and Acts of Parliament could do something for them, but could not make incapable men successful, or indolent men wealthy, or confer distinction without merit. He then referred to the social position occupied by pharmacists, and concluded with some words of advice to his hearers as to the adoption of habits of personal economy and the cultivation of the nobler parts of their moral and intellectual natures.

At the conclusion of the address, Mr. F. H. Alcock proposed a hearty vote of thanks to the President, which was seconded by Mr. Wrenn, and carried unanimously.

Obituary.

WILLIAM SQUIRE.

It is with deep regret that we are called upon to publish this week the death of Mr. William Squire, who until recently was the senior partner in the firm of Hearon, Squire and Francis, wholesale druggists, of 5, Coleman Street, E.C. The sad event took place suddenly on Thursday, the 11th inst., at his residence, The Grove, Feltham Hill. Although the health of the deceased had been in a failing condition for some time, the advance of infirmity was so natural as to restrain those graver fears which arise from the apprehension of imminent danger. Only within a few hours of his release did he evince any symptoms which could clearly be recognized as premonitions of an approaching end. The immediate cause of death was congestion of the lungs.

Mr. Squire was in his seventy-second year, having been born at Doncaster in 1812. He was apprenticed to the late Mr. Judson, chemist and druggist, Ripon, and at the expiration of his term in 1833 he came up to London to gain experience in a wholesale drug house. For a short time he was in the employ of Messrs. Hodgkinson and Co., and on leaving them he entered the then firm of Hearon, Bright and McCulloch. Here he went through the usual routine work, step by step, until he had acquired a thorough knowledge of the business requirements of each department of the house. He was then promoted to the road, a position which he amply justified by his almost unprecedented success as a traveller. Shortly an opportunity was afforded for his admission as a partner, an offer which he as gladly accepted as he had deservedly won.

As his new position entailed increased responsibility so he found wider scope for the exercise of his ability, and to his honour be it recorded that he brought his rare business capacity and tact to bear upon all that affected the commercial interests of the firm, so that he rapidly rose to be its presiding genius. He continued to be the ruling spirit until little more than a year ago, when, by his retirement, he brought to a close a most successful business career.

Although from the fear of notoriety the subject of our memoir shrank from taking part in pharmaceutical politics, he was always ready to lend a helping hand when by so doing he could further the interests of the members of his calling. The liberality of his gifts, cheerfully and unostentatiously distributed to not a few of his brethren in their time of pressing need, merits more than passing mention. Nor can we omit to refer to the assistance he has rendered the Pharmaceutical Society in his capacity as an auditor. In his riper years his advice was much sought after, and among his commercial compeers on the Drug Exchange he was reputed to be one of the best judges of the quality of drugs. Regarded as a man he was essentially a gentleman. Although naturally commanding, a dignified ease marked his bearing. Courteous ever in his address to a stranger, he occasionally appeared to be peremptory in his manner. A remarkable shrewdness characterized his observance of men and things, and he possessed to a large degree the rare faculty of discriminating character. Such are some of the qualities which contributed to his social advancement, and by their exercise he secured and maintained the hearty goodwill of his *employés*.

No surer evidence of the esteem in which the deceased was held could have been adduced than was supplied by the numerous gathering which assembled to pay its last tribute to his memory. In addition to the present members of the firm and a staff of the older servants, there were to be found among the mourners those who had come long distances from the provinces to seal their loyal devotion to an honoured friend.

Notice has also been received of the death of the following:—

On the 3rd of August, Mr. George Newlove, Chemist and Druggist, Stretford New Road, Manchester. Aged 62 years.

On the 27th of September, Mr. William Whincup, Chemist and Druggist, Essex Road, London, N. Aged 50 years. Mr. Whincup had been a Member of the Pharmaceutical Society since 1869.

On the 29th of September, Mr. Samuel Thomas Severs, Pharmaceutical Chemist, Lupus Street, Pimlico. Aged 36 years. Mr. Severs had been a Member of the Pharmaceutical Society since 1876.

On the 5th of October, Mr. Llewellin Palser, Chemist and Druggist, Wotton-under-Edge. Aged 64 years.

On the 5th of October, Mr. Peter Strang, Chemist and Druggist, High Street, Perth. Aged 53 years.

On the 7th of October, at Forest Gate, Mr. Frederick Hill Cumine, Chemist and Druggist, King's Lynn. Aged 64 years.

On the 8th of October, Mr. Samuel Sainsbury, Pharmaceutical Chemist, Strand, London. Aged 75 years. Mr. Sainsbury was one of the Founders of the Pharmaceutical Society, having been a Member since 1841.

Correspondence.

Liquid Extract of Cinchona.

Sir,—I have but now met with and read the paper by Dr. Paul, "On the Liquid Extract of Cinchona," reported in your issue of March 10, 1883. I have followed the discussion, and as I was the writer or "assisted" at the authorship of the paper read before the College of Physicians by Mr. Battley in 1838 and alluded to by Dr. Paul, I wish to add that I think Mr. Battley attained the object in view, viz., that of "separating and securing nearly the whole of the medicinal properties of the bark." Mr. Battley was aware that there was some quinine left in the residuum, but the preparation was a most elegant one, "leaving unchanged the medicinal qualities of the substance acted upon, separating and removing therefrom, as far as possible, every matter not possessing remedial virtue." It was very highly esteemed by Dr. Farre and other distinguished physicians of that day as offering a means of administering bark under circumstances when the patient could not take quinine, and I have little doubt that if the successor of the late Richard Battley continues, as is presumable, the same process, the preparation will long hold its own against all comers. In justice to another, it is not for me to recapitulate the operations, but I may say that the finest cordifolia bark procurable was used, that the water employed was cold, that it was not a mere digestion and evaporation, but a process of manipulation and elimination, and that no spirit was added at the completion; the result being that it was as uniform a product as could be made. Analysis could not determine the mode of manufacture; criticism did not deter its use. It grew rapidly in professional favour, and was approved by the highest authorities, and if pharmacists could have kept to this one most valuable medicine, instead of purchasing cheaper and much inferior imitations, much time and much fighting would have been spared, and the profession would not have been baulked in the use of an admittedly valuable remedy, still admitted to take high rank. Mr. Battley never advertised it, yet it found its way both in public and private throughout the country and abroad.

One of the speakers at the meeting observed that "the pharmacy of cinchona bark is in a great muddle." He says that "he had always looked on the fluid extract of cinchona contained in the Pharmacopœia as a continuation of a preparation which was originally brought before the College of Physicians by Richard Battley about the year

1830." The framers of the Pharmacopœia have much aided this state of things. Did they apply, before completing their work, to those who were acquainted with the matter in all its details? Did they? In the year 1830 I was working with Mr. Battley in his laboratory, and I can certify that the extractum cinchonæ liquidum of the British Pharmacopœia has no more relation to the "liquor cinchonæ" introduced by Richard Battley, as then and there prepared, than has the extractum opii liquidum to the "liquor opii sedativus" of the same discoverer. I would not have intruded these observations, but having been a party to the work of 1830 and 1838, by the late Richard Battley, I venture to do so.

12, *Wilson Street, Finsbury.* W. E. HEATHFIELD.

CHLOROPHYLL IN ANIMALS.

Sir,—As I find some inaccuracies in the account, published in the *Pharmaceutical Journal* of September 29, of my paper read before Section D of the British Association at Southport, I shall, with your permission, endeavour to give the necessary corrections.

What I discovered in invertebrate animals was not chlorophyll "in the intestines," but chlorophyll in the appendages of the intestine, *e.g.*, in the liver of Helix, Limax, Ostræa, Anodonta, in the pyloric corea of starfishes, and in the intestinal appendages of Echinus, etc. The finding of such pigment in the "intestine" of an animal would no more prove that the chlorophyll was formed by the animal, than would finding sulphate of copper in a man's stomach prove that he had synthetically built up that salt. The enterochlorophyll discovered by me is described in the current volume of the Royal Society's 'Proceedings' (No. 226, 1883), and my reasons for concluding that it is a synthetic production were given at Southport.

But I could not really have proved the correctness of my views if it had not been for this very Journal. As my attention was called to a paper by Mr. Pocklington, published in this Journal in 1873, in which he asserted that he had obtained proof, by means of the microspectroscope, of the presence of chlorophyll in the wing cases of cantharides, I repeated his experiments and can vouch for their accuracy, and I was able further to extend his experiments in such a manner as to prove beyond all doubt that the body found by him is chlorophyll. I called especial attention to his experiments in the paper read at Southport, and I now take this opportunity of observing that Mr. Pocklington deserves great credit for the work which he has done on the chlorophyll of cantharides.

The work of Sorby, Lankester and others had already shown that in Spongilla, Hydra, and some other invertebrates, chlorophyll was present, but Brandt, the Hertwigs, and others maintained that it was due to "symbiosis," *i.e.*, to living parasitic algæ, and the point which I wished to establish was, that such a view is incorrect with regard to its occurrence in other invertebrates, especially since Professor Carl Semper has endeavoured to extend this parasitic theory to all instances of the occurrence of chlorophyll in animals.

Wolverhampton.

THE CONFERENCE ADDRESS.

Sir,—As one who has taken a great though latent interest in the progress of pharmacy during the past ten years, I most heartily concur with Professor Attfield's suggestion of appealing to "the great mass of the community" by a distribution of the Conference address. Indeed, I intend that a copy shall come into the hands of every magistrate, medical man, or men who are aspiring for Parliamentary honours in the forthcoming compaign, including the coroner for this division.

Might I suggest that the Secretary of the Society should be instructed to request all Local Secretaries to make this one effort, as by acting collectively throughout the country we shall be reaching at least that part of the community who hold to a very great extent our interests at stake.

I regret that our Pharmacy Bill was not more closely associated with the Medical Bill which is shortly to come before the House, for a partnership, even if only a sleeping one, would have been not only more beneficial to medical men and pharmacists, but to the community at large.

Rugby. A. G. CHAMBERLAIN.

Sir,—Although many and grievous have been the complaints made of late by our suffering fraternity,—not by any means relieved by the statements contained in Professor Attfield's address at the British Pharmaceutical Conference,—the means proposed to alleviate the unsatisfactory condition of supply and remuneration in the drug trade have been comparatively few, which induces me to trouble you with a suggestion having for its object the bringing back the sale of medicines to the public to its legitimate distributors.

I propose that the Pharmacy Act should be amended and expanded by rendering it illegal for anyone to retail any drugs or compounds contained in the Pharmacopœia without the name and address of a pharmaceutical chemist or chemist and druggist attached to it (whose name is on the Register) upon the label; but that anyone, be he grocer or oilman, huckster, storekeeper or draper, or whatever his business, may be at liberty to supply the public, provided always that upon the label the chemist's name is distinctly printed, who must be responsible for its purity. This would be a simple and easy manner of defining the responsibility of the chemist on the one hand by reference to the Register, and on the other its being contained or not in the Pharmacopœia could be at once decided by reference to that official authority, both standards being already in existence and ready to hand. As the sale of medicines is becoming more and more convenient if supplied in packets or in bottles, and the Parcels Post forwards every parcel so cheaply and expeditiously, no complaint could possibly arise even in the most thinly populated district, that pure drugs were not within the reach of the public throughout the kingdom. The chemist need not be required to supply the drugs to the retailer himself, but having satisfied himself, after examining them, as to their quality and purity, supply his labels to the retailer at a price that would remunerate him for his knowledge and trouble, and the retailer, if he preferred, could purchase the articles himself elsewhere. The effect of this arrangement would be that the chemist would derive some benefit from all medicines sold, and the advantage of more widely circulating his name and qualification, and the public would no longer be supplied as at present from unsatisfactory sources with inferior drugs and adulterated compounds. I submit the above proposition as a simple and comparatively satisfactory solution of the disadvantageous position at present occupied by my brethren in the trade.

Wandsworth. GEORGE NIND.

W. H. P.—We are not aware that such a work has been published.

B.—Probably Mayne's 'Medical Vocabulary' (Churchills; price, 10s. 6d.) would answer your purpose.

"*Quærens.*"—According to section 16 of the Pharmacy Act, 1868, the previous sections relating to registration do not extend to the business of a legally qualified apothecary.

R. F. J.—The numbers mentioned are in stock and can be obtained through the publishers, Messrs. Churchill, 11, New Burlington Street, W.

W. P. F. Miller.—*Viburnum Opulus.*

G. Gordon.—(1) *Calamintha Clinopodium*; (2) *Stachys arvensis.*

Junior.—See a paper on "Glycerine Jelly," by Mr. Pocklington, in the *Pharmaceutical Journal*, [3], v., 401.

Inquirer (Ilfracombe).—The prescription is probably from a German practitioner, as all the ingredients ordered are in the German Pharmacopœia. The first is the artificial Carlsbad salt, which is a mixture, finely powdered, of sodium sulphate, dry, 44 parts; potassium sulphate, 2 parts; sodium chloride, 18 parts; and sodium bicarbonate, 36 parts.

J. A. H.—The process mentioned is the only one for the purpose with which we are acquainted; it is not dangerous if properly carried out.

F. A. Brown.—We have not met with the term: you are recommended to address your question to one of the journals associated with the iron industry.

Sub Umbra Floresco.—No formula for such a preparation has been published.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. R. H. Groves, Fitch, Plant, Williams, Schacht Siebold, Southall, Abraham, Ince, Barnes, Willmott Biologist.

"THE MONTH."

Probably the most important incident during the past month, in its bearing upon the treatment of disease, is the publication of the report of the German Scientific Expedition which was sent to Egypt to investigate the circumstances attending the recent outbreak of cholera in that country. Although the Commission did not arrive on the spot until after the virulence of the epidemic had considerably abated, the investigation at once set on foot under the able direction of Dr. Koch yielded results so interesting that an application was made to the German Government, and acceded to, that the Commission might be authorized to proceed to India and continue the study of the disease in its Asiatic home. One fact appears, however, to be already clearly established, namely that in every cholera corpse examined a particular form of bacterium, resembling in size and form the bacillus of glanders, was found in the coatings of the intestines. In some cases the bacilli had penetrated into the utricular glands of the mucous membranes and there set up considerable irritation; they also had settled in larger numbers on the villi of the intestines and had often penetrated into their tissue. In severe cases which had terminated in bloody infiltration of the mucous membrane of the intestines, the bacilli were found in very large numbers, and they had not confined themselves to the invasion of the utricular glands, but had passed into the surrounding tissue, into the lower layers of the mucous membrane and in some cases right into the muscular skin of the intestine. It is interesting to learn that similar bacilli were observed by Dr. Koch a year ago in a cholera-infected intestine received from India, but in that case the possibility of their having been a product of putrefaction was not excluded. As these bacilli were observed in Egypt in all the cholera cases investigated, and were not found in the intestines from several persons who had died from other diseases, or even in one case where a man had died from another disease a few weeks after he had recovered from an attack of cholera, Dr. Koch feels warranted in saying that there can be no doubt that they stand in some relation to the operation of cholera. But he is careful to point out that it cannot yet be concluded that they are the cause of that disease, and that it could just as well be assumed that the operation of cholera causes such disturbances in the mucous membranes of the intestines that among the many bacteria always parasitic in the intestines one form of bacilli is thus enabled to penetrate into the tissue of the mucous membrane. In order to determine this point it seems necessary to isolate and cultivate the bacilli and ascertain whether they are capable of reproducing the disease in a fresh subject; but in connection with this branch of the investigation there is a difficulty that has not yet been surmounted, in that no animal has yet been found which is susceptible to the choleraic poison. Dr. Koch and his colleagues have experimented upon mice and monkeys, dogs and poultry, but hitherto without results, although it was almost certain that some at least of the matter injected was capable of setting up the disease in a human subject. Another point of interest that requires to be cleared up, is the observation that in some places the epidemic dies out long before all the people have taken the infection, although infectious matter still remains scattered all over the district. This is thought to indicate that conditions arise under which the infectious matter loses some of its virulence.

Dr. Domingos Friere reports the discovery in the blood of patients suffering from yellow fever of an organism which he calls *Cryptococcus zanthogenicus*. He describes it as exhibiting minute points at first, and then large round cells with greyish or fringed margins and bright transparent centres. He believes that it does not lose its vitality when the body of a person who has died of yellow fever is buried; for having placed a guinea-pig in a chamber with earth taken from the grave of a man who died a year previously the animal died in five days, and its blood was found to be full of the characteristic organisms in various stages of development.

The possibility of the communicability of diseases through the instrumentality of flies has recently been pointed out by Dr. Grassi (*Brit. Med. Journ.*, p. 688). He found that the ova of human parasites which were exposed in a dish were taken in by flies at the mouth and discharged again unchanged in their fæces a few hours afterwards. The importance of protecting human food from flies and the necessity of keeping the rooms of persons suffering from infectious diseases free from flies is therefore obvious.

The change that takes place in the composition of gelatine under the influence of a digestive ferment has been the subject of an investigation by M. Tartarinoff (*Comptes Rend.*, xcvii., 713). The product of the action of artificial gastric juice upon gelatine was carefully analysed and yielded results showing that the modification is not a profound one and that the process of peptonization of gelatine is mainly one of hydration. The analytical results were also almost identical with those previously obtained in the analysis of products of gelatine by digesting it without pepsine in solutions of hydrochloric acid of varying strength and at different temperatures.

In a recent paper (*Pharm. Journ.*, [3], xiii., 603) Messrs. Dehérain and Maquenne recorded some observations on the action of a microscopical organism presenting the characters of the butyric ferment of Pasteur, which was found to be present in garden oil and capable of reducing the nitrates occurring in it. They now report the results of experiments in another direction and state (*Comptes Rend.*, cxvii., 803) that when the ferments of arable soil are allowed to act upon cane sugar in aqueous solution, at a temperature of 35° C., in the presence of calcium carbonate and sheltered from contact with air, there are produced small quantities of ethyl alcohol and still smaller quantities of superior alcohols; together with acetic, butyric and propionic acids in proportions representing nearly one-half the sugar employed, the acetic and butyric acids being by far the more abundant. These results therefore confirm the inferences drawn from the previous experiments that the dominant ferment in the soil belongs to the class of butyric ferments.

The residual pulp from the diffusion vats of beet-sugar manufactories is used largely in some parts of the Continent as cattle fodder, and has gained a reputation for favourably influencing the yield of milk from cows fed upon it. Some experiments made by Messrs. Andouard and Dézaunay show, however, that this is only partly the case (*Comptes Rend.*, xcvii., 809). It was found that "diffusion pulp" that had been preserved in a silo, when given to a cow in quantities at first of 27 kilograms and then of 55 kilograms daily, produced immediately an augmentation of 32 per cent. in the yield of milk, and that whilst the richness of the milk in caseine and mineral salts did not appear to be affected, the proportion of butter was increased 12·40 per cent. and that of sugar 23·64 per cent. But on the other hand the food appeared to communicate to the milk a less agreeable flavour, causing children to refuse to drink it, as well as a predisposition to the acid fermentation, and Messrs. Andouard and Dézaunay express a doubt whether butter of good quality could be made from such a milk. It is thought that this modification in the flavour may be attributable to the considerable proportion of acetic acid and homologues developed in the pulp by fermentation whilst in the silo, and that perhaps it might be avoided by using the pulp fresh from the presses.

Hippurate of sodium is said to be now attracting attention as a remedy for diseases in which the excretion of uric acid in excess forms a prominent feature. A few months ago Dr. Garrod called attention to the fact (*Lancet*, April 21, p. 672) that solutions of the alkaline hippurates when added to and allowed to remain for some hours with those of urates caused the disappearance of uric acid, so that it could not, after the addition of hydrochloric acid, be detected either by the microscope or by the murexide test. This action of hippuric acid upon uric acid is supposed by Dr. Garrod to take place in the urinary organs of herbivorous animals, since uric acid is found in the urine of suckling calves, but not when the animals feed entirely on vegetable food, hippuric acid being then found in the urine instead of uric. The urine of herbivorous animals is generally alkaline, whilst that of man is acid. Dr. Garrod therefore prefers the use of alkaline salts of hippuric acid, giving also some alkaline citrate if there be abnormal acidity of the urine. He states that in cases of gout, gravel and calculus he has obtained great advantage from the use of hippurate and benzoate of sodium, preferring the salts of potassium and lithium when he wishes to increase the quantity of the urinary excretion. Benzoate of sodium has a similar action to the hippurate, as might be expected from the fact that benzoic acid when absorbed from the stomach takes up glycine and becomes converted in the system into hippuric acid and is thus thrown out in the urine. The use of a vegetable diet which would give rise to the formation of benzoic or hippuric acid in the system might, Dr. Garrod thinks, be devised for those who suffer from the diseases above mentioned.

Benzoate of cinchonidine is recommended by M. Bouchardat in mild cases of diabetes with excessive production of uric acid. It is made, according to M. Byasson, by dissolving freshly precipitated cinchonidine, prepared from 200 parts of the sulphate, in a solution of 60 parts of benzoic acid dissolved in 200 parts of alcohol of 90 per cent., poured into a porcelain vessel containing 3000 parts of boiling distilled water. The solution of the salt before being allowed to cool should, if necessary, be rendered slightly alkaline by the careful addition of ammonia. The salt crystallizes out on cooling.

Tannate of sodium has been lately recommended instead of tannin to lessen the excretion of albumen in albuminuria; but the statements concerning its value are somewhat conflicting. Ribbert found that it lessened the excretion of albumen in animals. Dr. Brien, on the other hand, found in four carefully observed cases of patients suffering from chronic albuminuria, that it was of no use whatever; some patients can take it well, others vomit after every dose (*Practitioner*, Oct., p. 294).

The *Lancet* (Oct. 20, p. 704) gives a summary of some recent investigations of Albertoni on cotoin and paracotoin, which were published in the *Archiv für exp. Path. und Pharm.* (Sept., 1883). Albertoni finds that repeated small doses of cotoin increase the appetite of healthy men without causing unpleasant sensations and without producing constipation. It does not become dissolved in the gastric juice but passes unchanged in the intestines, where it would appear to be absorbed, as it is excreted by the urine. The falling off in the amount of indican in the urine during its use is supposed to be due to a secondary effect, which depends on the cure of the internal lesion. The experiments made show that cotoin can determine an active dilatation of the vessels of the abdomen, an action not known to be possessed by any other substance. Paracotoin is a weaker cotoin in its physiological action. Albertoni considers that cotoin is of value in the diarrhœa met with in the various forms of mental disease, in chronic intestinal catarrh, in looseness of cachectic states, and in the relaxation of pellagra, phthisis and rickets. Its use is contraindicated in states of severe hyperæmia of the intestines, and where a tendency to melæna exists. Doses of 15 and 20 centigrams per day were thought to be more effectual than smaller ones. The administration of bismuth with cotoin is suggested as likely to be of special value.

The question of the medicinal effects of the spiritus ætheris nitrosi of the B.P. has received attention from Dr. Leech, of Owens College, who has published the results of his investigations in the *Practitioner*. He considers its action as analogous to that of nitrite of amyl, and that it is a distinct depressor of arterial tension. Its diuretic action he attributes to its effect on the circulation. The samples used in his experiments answered to the B.P. test and contained but little aldehyde. It may be hoped that his investigations may be carried further, and that the influence of paraldehyde on the effects of spirit of nitrous ether may be taken into consideration, since Mr. J. Williams has pointed out that it is a possible ingredient in sweet spirit of nitre, inasmuch as the odour of the latter closely resembles that of paraldehyde.

Dr. Méhu calls attention (*Journ. Pharm.*, [5], viii., 339) to the property possessed by glycerine of removing certain compounds from ethereal solutions, which might have an important bearing in analytical investigations. He has found that upon shaking an ethereal solution of ferric sulphocyanide or perchloride with glycerine, the glycerine takes up the whole of the ferric salt leaving the ether colourless; similar results follow with ethereal solutions of chloride of gold, nitrate of uranium, or the violet liquid produced by shaking an aqueous solution of methylamine violet with ether. In other cases glycerine appears only to remove a portion of the compound dissolved in the ether; among these Dr. Méhu mentions mercuric chloride.

Whilst engaged in the operation of preparing theobromine from cacao beans Herr Schmidt has observed (*Archiv*, [3], xxi., 675) the separation from the last mother-liquor of a small quantity of long acicular crystals, corresponding in appearance and behaviour with caffeine, which was obtained pure by dissolving in cold benzol and recrystallizing the evaporation residue from hot water. The occurrence of a second crystalline alkaloid, "existing in larger quantities in some descriptions of cocoa than in others, and in larger proportion in the husk than in the kernel," had been previously recorded by Mr. Bell (*Anal. and Adult. of Foods*, p. 85) who, however, only speaks of it as a "theine-like alkaloid," containing 25·48 per cent. of nitrogen (anhydrous caffeine contains 28·86 and with one molecule of water 26·41 per cent.). Herr Schmidt, however, found the alkaloid to be identical with caffeine, and the gold salts to correspond exactly in appearance and in composition. The two alkaloids may be separated by taking advantage of their different solubility in cold benzol.

A commercial specimen of ammonium bromide submitted to analysis by Herr Schmidt is reported (*Archiv*, [3], xxi., 679) to have contained a very considerable quantity of soluble barium salt, the addition of dilute sulphuric acid to an aqueous solution (1 in 20) having produced a copious precipitate of barium sulphate.

According to Herr Ost (*Journ. f. prakt. Chemie*, xxviii., 271) commercial ammonia frequently contains small quantities of pyridine, which is not surprising, since the gas liquor from which ammonia is principally obtained is known also to contain pyridine. The pyridine may be detected by incompletely neutralizing the ammonia with hydrochloric acid; the pyridine is the last to combine with the acid, and becomes easily perceptible by its intense odour as the saturation approaches completion. It appears that both pyridine and pyrrol occur in the majority of specimens of crude ammonia.

In an interesting paper published some time since (*Pharm. Journ.*, [3], xii., 706) Mr. Kennedy gave a description of the distillation of oil of birch bark (*Betula lenta*) in Schuylkill county, Pennsylvania, and mentioned that the oil was sent into the market as oil of wintergreen, with which, with the exception of a slight difference in the boiling point, he thought it was identical. Subsequently a sample of the oil was examined by Mr. Pettigrew, who arrived at the conclusion that the volatile oil of birch differs from that of gaultheria in that it consists entirely of salicylate of methyl and contains no terpene, and that the specific gravity (1·180) attributed in the new United States Pharmacopœia to oil of gaultheria is really that of oil of birch, the specific gravity of oil of gaultheria being 1·0318. From some further information communicated by Mr. Kennedy to the American Pharmaceutical Association it appears, however, probable that a quantity of terpene is lost during the distillation of oil of birch, which is carried on in a very crude way, for whilst the heavier portion of the distillate (salicylate of methyl) which sinks to the bottom is collected, another portion which floats on the surface and is known among the distillers as "light oil" and "light ring" is washed away and lost. It would appear that in some parts of Pennsylvania the products of the distillation of the leaves of *Gaultheria procumbens* and of the bark of *Betula lenta* are mixed indiscriminately, one or the other preponderating according to the relative abundance of the material in the locality, and the mixture being sent into the market as "oil of gaultheria." The quantity produced is very large, amounting last year, in the counties of Carbon and Monroe alone, to twenty tons.

In a paper read before the American Pharmaceutical Association Mr. Colcord mentions that he has found an admixture of glycerine with strained honey prevent crystallization for a considerable time. The honey was placed in a bottle in a water-bath and as soon as it had melted the glycerine was stirred in in the proportion of an ounce to a pound and a half. As this was a first attempt it would seem to be worth experimenting as to the smallest quantity of glycerine that would suffice for the purpose.

According to another paper read before the American Pharmaceutical Association the annual production of bromine in the United States amounts to from 450,000 to 500,000 lbs. It is obtained from the bittern of salt-wells—*i.e.* the residue after the salt has been removed from the brine—and in six localities named the bittern is so rich that for every two barrels of salt it yields one pound of bromine. The separation of bromine is said to be now carried on at all the brine works where it can be conducted profitably, and unless fresh deposits are discovered the production is more likely to decrease than increase.

According to the *Scientific American*, the "steaming" of windows, and the frosting of panes consequent in cold weather, may be prevented by coating them with a slight film of glycerine.

Twenty years ago comparatively little attention was paid to physiological botany; but since that date, and especially during the last few years, it has been cultivated almost to the exclusion of descriptive botany, and systematic botanists have been at a discount as teachers of botanical science. This has been especially the case in Germany. But the cultivation of any science in one particular line to the neglect of other branches naturally leads after a time to a reaction, and this, we learn from the *Gardeners' Chronicle* (p. 500), has recently manifested itself. Dr. Schweinfurth, the celebrated traveller, at a meeting of German naturalists and physicians at Fribourg last month, when dealing with the present state of botany in Germany, pointed out that there were everywhere traces of the consequences of the exclusive cultivation of the anatomical and physiological branches of botany. Teachers were wanting, botanical gardens were falling into decay, and the directors of these establishments looked down with contempt on the few representatives still remaining of the old school of botanists. There can be no doubt that even in this country Sachs' 'Text-book of Botany' has had considerable influence both on the character of the teaching and of the examinations in this country, but systematic botany can hardly be said to be neglected in England at present. The declension, in systematic works on botany, of the old practice of giving some account of the economic uses of the plants described in them is, however, very noticeable and much to be regretted, since, often, it is not to be obtained elsewhere without a considerable expenditure of time and trouble. Dr. Schweinfurth gives as an example of what ought to be done in relation to cultivated plants, by mentioning that *Pennicillaria*, a tropical grass which affords food for 50,000,000 or perhaps even 100,000,000 persons, is practically unknown and not alluded to even in the most recent works.

The practical value to the world in general of the scientific study of botany must be in its application to the wants of mankind. An instance of this truth has recently forced itself upon the attention of the public. A short time since a parliamentary paper issued relative to an investigation carried out by Messrs. McDougall Bros., on behalf of the Secretary of State for India, on the quality of Indian wheat (see *ante*, p. 161), showed that while four Indian wheats were hardly equalled by any other kind for what is wanting and deficient in the English market, and while the flour yielded a larger proportion of bread than any other wheat examined, yet these wheats possessed a distinctly beany almost aromatic flavour, which would prove to a certain extent a bar to their general use. Some light has now been thrown on the probable cause of this flavour by M. Balland (*Comptes Rendus*, xcvii., 805) who has examined Indian wheat and found several leguminous seeds in the varieties exported from Bombay. A mixed sample taken from several sacks gave three leguminous seeds per 100 of wheat. Among those which were detected, and which have been determined by M. Léon Masse, are the seeds of *Vicia peregrina*, 1·2 per cent.; *Cicer arietinum*, var. *nigrum*, 0·7 per cent.; *Ervum uniflorum*, 0·2 per cent.; linseed, 0·05 per cent. A few seeds of *Cajanus indicus*, *Acacia Lebek*, *Tamarindus Indica*, *Cassia?*, *Rhyncosia?*, *Citrullus vulgaris* and *Ricinus communis* were removed by sifting. It is not surprising, therefore, that wheat containing these seeds, especially castor oil seeds, should have a peculiar flavour.

A similar injurious admixture in Californian wheat has been recently pointed out by Mr. W. Southall (*Miller*, Oct. 1, p. 586). The sample examined contained a quantity of the seeds of *Melilotus alba* and *M. parviflora*, and lesser quantities of black mustard, *Centaurea melitensis*, a species of spurrey and several others. The want of agricultural care in excluding weeds from the vegetable crops and in the collection of products has no doubt a considerable influence in preventing the full development of the resources of our great Indian Empire. The linseed imported from our Indian provinces would be much more valuable in the market if care were taken to exclude foreign seeds, while gum acacia and various resins, if cleanly collected and carefully sorted, would doubtless pay for the care bestowed upon them. Considering how rapidly many introduced weeds spread in a new country, one means of excluding weed seeds would be to carefully sift the grain before sowing it.

Mr. A. S. Wilson in his remarks "On the Closed Condition of the Seed-vessel in Angiosperms," has made some interesting suggestions with regard to the use of the pistil or carpels. He believes they serve to guard the ovules from any external influence that would tend to degrade their chemical constitution or lead to a misappropriation by fungi of the nutritious matters they contain; that in fact the loose cellular substance of the style and the acid secretion on the stigma may serve to filter the air before it reaches the ovules (*Nature*, Oct. 11, p. 581).

A case of poisoning by laburnum pods is recorded in the *British Medical Journal* for October 13 (p. 728). The symptoms were the same as usual. The remedies used for the patient, a boy seven years of age, were mustard and water to assist the vomiting, and subsequently a teaspoonful of aromatic spirit of ammonia well diluted with water.

Another case is mentioned in the *British Medical Journal* (p. 675, October 6), in which two children and a nursemaid were poisoned by laburnum seeds. In this case brandy was the stimulant used to overcome the narcotic influence of the seeds, and recovery took place in due course.

Medicinal plants in blossom are now becoming fewer every week. Nevertheless, a communication has been received from Mr. R. I. Lynch to the effect, that the following may be seen in flower in the Cambridge Botanic Garden at the present time: *Chenopodium anthelminthicum*, the oil of the seeds of which is well known in the United States as an anthelminthic; *Linum usitatissimum* and *L. catharticum*; lavender, tobacco, the castor oil plant, hemp, and the singular rose of Jericho, *Anastatica hierochuntina*. *Ecballium officinarum* is also now in good condition for collecting the fruit. Buckthorn berries and rose hips are also in a fit state for gathering. At the Botanic Garden, Regent's Park, the *Eriobotrya japonica* is now in full blosssom; *Olea fragrans* perfumes the Economic house with its delicious odour, and *Petiveria alliacea* is in full blossom.

At the drug sales this month, a small parcel of gamboge in tears was offered for sale, and some Jamaica jalap of excellent quality, which was quickly purchased. Some spurious cinchona bark (*Stenostomum acutatum*) was put up for sale, but it does not appear to have met with a purchaser. Some saffron, in which marigold flowers dyed with nitrocresylate of sodium were mixed, has been met with in commerce during the last few weeks, possibly from the same source as that recently detected in Russia.

THE NEW PATENT LAW.

The following has been sent for publication:—

"With the object of affording information to the public until the new rules* under the Act are completed, the following information is issued by direction of the Board of Trade:—

"1. Applications and all other documents will be required upon strong, wide-ruled foolscap paper (written or printed on one side only), having a margin of 2 inches on the left-hand part thereof. The use of parchment will be discontinued. Copies of specifications will no longer be required.

"2. The sizes of the drawings will remain unchanged, but they will be required upon drawing-paper instead of on parchment. A copy of the drawings will be required upon thin Bristol board.

"3. Forms of application (stamped) will be placed on sale at the chief post-offices in the United Kingdom.

"4. The forms required for an application will be—(*a*) for provisional protection—application form and form of provisional specification; (*b*) for complete protection—application form and form of complete specification. Where a complete specification is not left in the first instance, it may be left at any time within nine months after application for provisional protection.

"5. The fees will be £1 for each stamped form of application and £3 for each stamped form of complete specification. No fee will be charged for the form for provisional specification.

"6. Applications may be left at the Patent Office or sent by post. If sent by post, they must be addressed to the Controller, Patent Office.

"7. The 'declaration' in the application form must be made by the inventor or inventors. All other documents may be prepared and signed by agents.

"Note.—'Applications' for letters patent made during the present year must be proceeded with in accordance with the existing laws and rules.

"H. Reader Lack.

"Office of Commissioners of Patents,
"25, Southampton Buildings, Chancery Lane."

The Pharmaceutical Journal.

SATURDAY, OCTOBER 27, 1883.

Communications for the Editorial department of the Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE LOCAL GOVERNMENT BOARD ON THE SALE OF FOOD AND DRUGS ACT.

IN accordance with what has now become an annual custom, the Twelfth Annual Report of the Local Government Board that has just been issued contains about a dozen pages devoted to an official commentary upon the statistics returned to the department under the provisions of the Sale of Food and Drugs Act. Probably a considerable portion of this elaboration might have been omitted without any very serious loss to the public, but, on the other hand, there are some points in it worthy of consideration and comment. Decidedly, however, the most definite impression produced by the reading of the report is a sense that whatever part the Act may play as a terror to evil doers, it is nevertheless, as a legislative performance, far from being a credit to the statute book. In fact the present report seems to show clearer than ever that the Sale of Food and Drugs Act is a law that is disobeyed, evaded or burlesqued with impunity at the pleasure or to suit the convenience of any of the authorities entrusted with the duty of carrying it into effect. In justification of this remark we would say that in the first place it took at least half-a-dozen years to persuade a fair proportion of the local authorities to make the appointments necessary for a show of enforcing its provisions, and now when analysts have practically been appointed throughout England it is found that in a large number of cases the post is allowed to become a sinecure. The public analysts for the five counties of Berks, Dorset, Hereford, Hertford and Suffolk do not appear to have been troubled with a single sample to analyse during the year 1882, whilst those for another five counties—Cambridgeshire, Cornwall, Northumberland, Shropshire and Westmoreland—received only forty samples between them. Turning to the boroughs, it is found that from sixty-nine, with an aggregate population of more than a million, the reports are "absolutely *nil*;" whilst in such boroughs as Ashton-under-Lyne, Blackburn, Coventry, Durham, Kidderminster, Middlesborough, Northampton, Nottingham, Oxford, Plymouth, Preston and Rochdale the Acts are reported to have been "entirely, or almost entirely ignored." In sharp contrast to the foregoing stands the statement that in the metropolitan district alone there were 5401 samples examined, or nearly 28 per cent. of the whole number in England and Wales.

In addition to the unequal and irregular manner in which the law is carried out or ignored in different parts of the country, the statistics in the "Abstract of Reports of Public Analysts" betray something more than a suspicion that a wide divergence obtains in the manner of interpreting analytical results. Thus taking the samples included under the heading of drugs, we are told that 387 samples were examined, which were all obtained either in the metropolitan district or in one of twenty-three counties. Of these all the samples (65) collected in the metropolitan district were reported to be unadulterated, and a similar remark applies to all the samples examined in fifteen of the counties. Nevertheless with this clear sheet for Greater London and two-thirds of the counties in which drugs were examined, we are gravely assured that in the other eight counties the adulteration of drugs was so exceptional—for instance, in Durham, 14 samples out of 35—as to bring the proportion of samples adversely reported upon up to 14·5 per cent. of the whole quantity examined throughout the country. But this absence of any approach to uniformity is not confined to drugs, and is evidently to be attributed rather to the idiosyncrasies of the local officials than to such a piebald character in the national trading morality as would otherwise be indicated by the statistics quoted. Putting on one side as misleading some ridiculous averages on small numbers that are given, we are told that in the county of Derby 52 samples out of 169, or nearly 31 per cent., were adulterated, and in the extra-municipal districts of Warwickshire 77 out of 324, or about 24 per cent., were reported against. On the other hand, in Gloucestershire, of 552 samples only 7, or 1·4 per cent., were returned as adulterated; in Leicester, only 1 out of 119; and in Mile End Old Town, out of 32, none. The whole set of statistics being subject to these disturbing influences we are afraid that the information that the adulteration detected in 1882 exceeded that of the previous year by 0·40 per cent.—15·07 against 14·67 per cent.—is not an overwhelmingly important contribution to the public knowledge.

Another failing that vitiates and impairs the value of these returns is the almost total absence of information as to how many prosecutions were instituted in reference to the 2931 reported cases of adulteration, and in what proportion of these convictions were obtained. In the one instance where such information is given,—for the county of Essex,—it is stated that in respect to 98 samples that were reported to be adulterated, including 45 of milk and 30 of gin, 60 convictions were obtained, and, as the official reporter puts it hypothetically, "*if*" the same proportion obtained elsewhere it might be assumed that proceedings were successfully taken in respect of rather less than two-thirds of the whole

2931; a very safe remark, but otherwise not of much value. However, taking the figures for what they are worth it appears that in percentage proportion of adulteration "spirits other than gin" again headed the list with 26·3 per cent.; then followed gin with 23·6 per cent.; milk with 19·6 per cent.; coffee with 18·7 per cent.; mustard with 17·9 per cent.; drugs with 14·5 per cent., and other articles ranging from that figure to as low as 0·6 per cent. in the case of flour. With respect to drugs regret is again expressed in the report that so few samples—only 387—were examined; but it is satisfactory to learn that the Local Government Board, more susceptible to emotion than such bodies are usually supposed to be, is made "glad" by a minute "diminution in the adulteration of drugs," so far as it is evidenced by the figures showing a fall from 15 per cent. in 1881 to 14·5 per cent. in 1882. We, on our part, should be "glad" if the Board evinced a clearer perception of the probable nature of the great majority of the cases classed under drugs. One remark in the report, to the effect "that the difference between a genuine and an adulterated medicine may be a matter of life or death for the patient," might be passed over for its triteness did it not imply a belief in the existence of a practice which we venture to say is not established by any evidence brought under the notiee of the Board in the reports; whilst another remark that "it is noticeable that in some cases the drugs condemned were bought not from chemists but from grocers" is an ingenuously perverse way of stating the facts. Indeed the Board seems disposed to be quite sympathetic towards grocers, for the report enlarges upon the "difficulty" experienced by those tradesmen in respect to paregoric, since if they sell a genuine article they are liable to a penalty under the Pharmacy Act, whilst if they supply a spurious one they come within reach of the Sale of Food and Drugs Acts. Surely the difficulty is only of the nature experienced by all persons who seek to evade the statute law.

Athough we have ventured thus to criticize some of the features in this report which appear to us to be more or less unsatisfactory, we readily recognize that these imperfections arise from defects in existing legislation rather than from any shortcomings of the Board to which, amongst other multifarious duties, it falls to report upon work done under an Act that accords to it a minimum power of control. We believe, indeed, that in the past the Board has exercised an extremely healthy influence upon the manner in which the Act is carried out, and we are glad to observe in the present report an injunction to over-zealous officials to remember that the Sale of Food and Drugs Acts are not intended to prevent the sale of poor articles, but that of adulterated articles. Pointing in the same direction there is printed in the Appendix an extract from a letter received by the Board from the Principal Chemical Officer of the Commissioners of Inland Revenue, expressing an inability to adopt the "definitions" and "limits" for genuineness of milk laid down by the Society of Public Analysts, for the simple, but all-sufficient, reason that they are not borne out by analyses of hundreds of samples known to be genuine.

The *Medical Press and Circular* for the 24th inst., in an editorial article, referring to the statement made at the recent annual meeting of the Pharmaceutical Society of Ireland by the retiring President that the Society was "fairly prosperous," finds it difficult to accept this hopeful view of its position, and expresses an opinion that there "must be something radically wrong when an institution which is—practically—in command of pharmacy in Ireland is not able to do more at the end of twelve years than maintain a languishing existence." Our medical contemporary is not disposed to blame the past officers for any dereliction of duty, but maintains that the fatal error which has resulted in the Society "being well-nigh starved out of existence" consisted in the neglect to exercise the power conferred under the Act to license two grades of pharmacists,—the pharmaceutical chemist and the chemist and druggist. It further alleges that the first Council of the Society, having been composed in great majority of doctors and apothecaries, was not likely to see the propriety of setting up a large class of rival dispensers throughout the country by licensing chemists and druggists under the Act, and "deliberately elected to narrow the operations of the Society to the few Irish towns in which a high class pharmacist can live." In conclusion, a hope is expressed that "the new Council and its new President and Vice-President will mark their accession to office by inaugurating a policy of liberality and by manifesting that they realize the fact that their duty to the public is higher than their obligation to protect their own class at the public expense."

* * *

Apropos of a notice that appeared in the *Times* of some recent translations of German text-books on botany, a correspondent has called attention to the long time that frequently elapses between the appearance of the original work and that of the translation, as well as the usually great disparity in the price of the two editions. As to the apparent delay there may be a sufficient explanation in the fact that it is necessary for a book to acquire some reputation before a publisher could be expected to venture upon its reproduction in another language, and besides this there is the time required for translation and printing. But it must be confessed, it is not quite so clear why a copy of an English translation of a German scientific work shonld as a rule cost from 50 to 100 per cent. more than a copy in the original language.

* * *

The dispute to which we referred a short time since as having cropped up between the United States customs officers and importers of chemicals as to the liability to pay duty on sulphate of cinchonidine has been terminated by a decision of the Treasury department that the salt shall be allowed to enter the country free of duty. This decision, although opposed to the strict reading of the Act, is probably in conformity with the intention of the framers of the new United States tariff law.

* * *

The above dispute having been thus disposed of, another appears to have taken its place, as to the liabilty to pay import duty on carbolic acid. One section of the Tariff Act provides that acids used for mechanical, chemical or manufacturing purposes, unless specially enumerated or provided for otherwise in the Act, shall be free from duty, and as carbolic acid is not mentioned by name and comes fairly within the definition as used for medicinal purposes, it might have been deemed by a superficial reader to be exempt from duty. But another section of the Act provides that all preparations of coal tar, not colours or dye, and not specially enumerated or otherwise provided for, shall be subject to a duty of 20 per cent. *ad valorem*, and the customs authorities claim that this section covers carbolic acid.

* * *

The *Canadian Pharmaceutical Journal* reports a case that has occurred at a place called Mount Bridges, in which the death of three children followed quickly upon the administration to them of a substance that had been supplied as santonin. At the inquest the jury came to the conclusion that the substance supplied was strychnine, and returned a verdict accordingly. The seller, who has been arrested, was not a qualified druggist, but was acting as a temporary manager of branch business, the owner of which is also unregistered.

* * *

On Wednesday last, a presentation was made to Professor Bentley on the occasion of his retiring from the post of Dean of the Medical Faculty of King's College, London. The testimonial consisted of an illuminated album, containing an address and a list of the subscribers, together with a purse.

* * *

The number of full entries of students at the metropolitan medical schools this session is unusually large, being 609, as compared with 461 in 1879, 468 in 1880, 472 in 1881 and 371 in 1882. The school at St. Bartholomew's heads the list with 120 entries, and University College follows next with 83.

* * *

According to a statement in the Report on the Botanic Gardens and Government Plantations in South Australia applications for medicinal herbs have become frequent, and among those that Dr. Schomburgk speaks of as having been supplied, are the common English broom (*Cytisus scoparius*), a decoction of which is used for dropsy in the colony; the leaves of the mullein (*Verbascum Thapsus*), a decoction of which is used as a remedy in consumption; and the globular spurge (*Euphorbia pilulifera*), a decoction of which is said to be used with good results in asthmatic complaints.

* * *

We publish on another page the new rules that have been issued by the Board of Trade under the Patent Acts of last session. It will be seen that they promise to decrease the expenditure of time and money by inventors, whilst the utilization of the post offices as depôts for the forms of application will no doubt prove a great convenience.

* * *

The first meeting of the Chemical Society in the new session will be held on Thursday next, November 1, when papers will be read on "The Production of Hydroxylamine from Nitric Acid," by D. Divers; "Some Compounds of Phenols with Amido-Bases," by G. Dyson; and the "Chemistry of Lacquer (Urushi)," by H. Yoshida.

* * *

At at meeting of the Chemists' Assistants' Association to be held on Wednesday evening next, the 31st inst., a paper on "New Remedies," by Mr. J. F. Burnett, will be read.

Transactions of the Pharmaceutical Society.

EXAMINATIONS IN LONDON.

October 17, 1883.

Present—Mr. Carteighe, President; Mr. Atkins, Vice-President; Messrs. Barnes, Benger, Brady, Corder, Ekin, Fletcher, Gale, Greenish, Linford, Plowman, Southall, Tanner, Taylor and Thresh.

Dr. Greenhow attended on behalf of the Privy Council.

MAJOR EXAMINATION.

Six candidates were examined. *Three* failed. The undermentioned *three* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Evans, Evan James ....Aberystwith.
Jones, Frank.................. ......Manchester.
Longtoft, William ....Bedale.

MINOR EXAMINATION.

Nineteen candidates were examined. *Ten* failed. The undermentioned *nine* passed, and were declared qualified to be registered as Chemists and Druggists:—

Barton, Francis ....Guernsey.
Baxter, William ....Bromley.
Beck, William Henry ....Selby.
Blades, William Wrench.........Northwich.
Boyden, Alfred Ernest ....Burnley.
Briggs, George William ....Bulwell.
Burn, James William ....Flintham.
Clarke, Herbert ....Lowestoft.
Clayton, George ....Manchester.

October 18, 1883.

Present—Mr. Carteighe, President; Mr. Atkins, Vice-President; Messrs. Barnes, Benger, Brady, Corder, Ekin, Fletcher, Gale, Greenish, Linford, Plowman, Southall, Tanner, Taylor and Thresh.

Dr. Greenhow attended on behalf of the Privy Council.

MAJOR EXAMINATION.

Five candidates were examined. *Three* failed. The undermentioned *two* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Ord, Septimus William ....Newcastle-on-Tyne.
Puckey, Courtenay ....Herne Hill.

MINOR EXAMINATION.

Twenty candidates were examined. *Fifteen* failed. The undermentioned *five* passed, and were declared qualified to be registered as Chemists and Druggists:—

Cole, William ....West Cowes.
Doubleday, Frederick Wm......Norwich.
Farman, Bartholomew Robert...Norwich.
Farrer, Edward .. ..Kendal.
Fletcher, Francis Round.........Netherton.

October 19, 1883.

Present—Mr. Carteighe, President; Mr. Atkins, Vice-President; Messrs. Barnes, Benger, Brady, Corder, Ekin, Fletcher, Gale, Greenish, Linford, Plowman, Southall, Tanner, Taylor and Thresh.

MINOR EXAMINATION.

Twenty-five candidates were examined. *Sixteen* failed. The undermentioned *nine* passed, and were declared qualified to be registered as Chemists and Druggists:—

Davies, Daniel ....Saundersfoot.
Gibson, John.........................Barnard Castle.
Gray, William Underwood......Lincoln.
Harding, John William ....Macclesfield.
Harold, John Patrick ....London.
Jones, Ivor Lloyd...................Swansea.
Loeffler, George Berthold ......London.
Mann, William.......................Leicester.
Marshall, Sam ....Hyde.

October 24, 1883.

Present—Mr. Carteighe, President; Mr. Atkins, Vice-President; Messrs. Barnes, Benger, Brady, Corder, Ekin, Fletcher, Gale, Greenish, Linford, Plowman, Southall, Tanner, Taylor and Thresh.

MINOR EXAMINATION.

Twenty-five candidates were examined. *Twelve* failed. The undermentioned *thirteen* passed, and were declared qualified to be registered as Chemists and Druggists:—

Jones, James Herbert............Liverpool.
Mitchell, Thomas Maxwell......Leeds.
Nobbs, Arthur Perkins ....Newport, I. W.
Notcutt, William Brighty ......London.
Owen, David James...............Swansea.
Price, Henry Thomas ....Shrewsbury.
Pumphrey, Arthur ....York.
Reade, Leonard James ....Wolverhampton.
Rutherford, Fredk. A. Regd....Bristol.
Sharp, Stephen ....Heywood.
Smith, Alexander Newsome ...Radford.
Smout, Charles Lickfold.........London.
Turner, Thomas ....London.

October 25, 1883.

Present—Mr. Carteighe, President; Mr. Atkins, Vice-President; Messrs. Barnes, Benger, Brady, Corder, Ekin, Fletcher, Gale, Greenish, Linford, Plowman, Southall, Tanner, Taylor and Thresh.

Dr. Greenhow attended on behalf of the Privy Council.

MINOR EXAMINATION.

Twenty-five candidates were examined. *Eighteen* failed. The undermentioned *seven* passed, and were declared qualified to be registered as Chemists and Druggists:—

Jones, John Richard ....Swansea.
Price, Charles Cleaver............Bristol.
Richards, Benjamin... ....St. Dogmells.
Turner, John Edward............Woodbridge.
Wokes, Thomas Siminson ......Hull.
Woodruff, Albert Edward ......Sandwich.
Wrenn, William Albert ....Penge.

PRELIMINARY EXAMINATION.

The undermentioned certificates were received in lieu of the Society's examination:—

Certificates of the College of Preceptors.

Lawton, Charles Edward ......Lockwood.
Petter, Edward Arthur ....Folkestone.
Tomlinson, Frank Lofas ....Manchester.
Vercoe, John Lean ....Holywell.
Walker, Richard Thomas ......Wigan.

Certificate of the Royal College of Surgeons of England.

Calkin, John Ernest ....Salisbury.

Certificates of the University of Cambridge.

Foot, Wm. Rolstone Whiteway.Totnes.
Jones, Martin Llewelyn ....Aberdare.
Newbold, Victor Emanuel ......Sutton.
Richardson, Thos. Wm. Percy .Ryde.
Sage, Edward Thomas............Atherstone.
Smyrk, Frank Alfred ....Evesham.
Walden, Henry Ernest ....Southampton.
Wardley, James ....Birmingham.
Wilkinson, J. Edw. Beaumont...Manchester.

Certificate of the University of Durham.

Leech, Frederick Samuel ......Gateshead.

Certificates of the University of Edinburgh.

Burnett, John D.............. .....Fraserburgh.
Speedie, Robert ....Edinburgh.

Certificate of the University of London.

Farnworth, Walter ....Blackburn.

Certificates of the University of Oxford.

Huskisson, Owen Dudley ......London.
Routley, Edwin Walter ....Bath.

The report of the College of Preceptors on the examination held on October 2 was received.

Three hundred and ninety-one candidates had presented themselves for examination, of whom *two hundred and twelve* had failed. The following *one hundred and seventy-nine* passed, and the Registrar was authorized to place their names upon the Register of Apprentices or Students:—

Abbott, Alfred Arthur............Alresford.
Alexander, John ....Aberdeen.
Anthony, Thomas..................St. Austell.
Anderson, George William......Thirsk.
Baker, Harry Ernest ....Bristol.
Bell, Charles Bains ....Hull.
Bell, William Irving ....Shipley.
Blair, Thomas ....Glasgow.
Bond, Arthur Lawrence.........Tiverton.
Brough, William Hamond ....Brechin.
Brown, Henry Armstrong ......Sunderland.
Burnett, Augustus Frederick...Highbridge.
Carter, Thomas Jos. Walmsley..Fulwood.
Charlton, Kate.......................Birmingham.
Colebank, John.....................Carlisle.
Coleman, Walter Graham ......Leicester.
Comyns, Joseph Robert ....Maryport.
Craig, Andrew.......................Aberdeen.
Crerar, Donald B. ....Crieff.
Cumming, John ....Aberdeen.
Davenport, Richard C. ....Talgarth.
Davies, Evan James ....Cardigan.
Davies, Griffith.....................Cardigan.
Davies, John..... ....Llandovery.
Davy, Harry Richard ....Leicester.
Dumaresq, Rawlings ....Guernsey.
Dunsford, Thomas William......Modbury.
Edward, Robert F. Sharp ......Aberdeen.
Emmett, Charles Ernest.........Dartmouth.
Evans, David William.............Llansadwrn.
Farquhar, John McKelvie ......Greenock.
Ferguson, John Eustace ....Birmingham.
Ferriday, Arthur Harry ....Oakengates.
Fifield, Tom Hadley ....Birmingham.
Fothergill, Alfred...................Newport, Mon.
Fowlds, William ....Keighley.
Francis, John Hancorne ....London.
Frayn, Alfred ....Stonehouse (Devon).
Gammidge, Albert Edward ...Leicester.
Gillespie, John ....Glasgow.
Glover, Arthur Sandon ....London.
Godding, William ....Tunstall.
Grant, Duncan.......................Montrose.
Grayson, John Henry ....Whitehaven.
Guerin, Alfred Bishop ....London.
Hagen, Frederick John ....Bristol.
Haggis, Henry Charles ....Portsmouth.
Hague, Charles Henry............Ashton-under-Lyne.
Hall, James ....Leicester.
Hallam, Samuel Robinson ......Burton-on-Trent.
Hampson, Herbert Edwin ......York.
Harrison, Amos ....Horsley.
Hart, Jane ....London.
Harvey, Ernest James............London.
Hayhurst, Robert....................Mexborough.
Heap, Isaac Henry ....Hanley.
Hearnshaw, Fossey John C......Southport.
Heaton, John ....Rastrick.
Henderson, John Beattie ......Accrington.
Henderson. Thomas Cuthbert...Lochee.
Hendry, Patrick Muir............Edinburgh.
Henry, James ....Galashiels.
Henry, James ....Canonbie.
Hepworth, John Stafford ......Hyde.
Hetherington, Thomas............Moffat.
Hind, William Tom...............Leicester.
Hobbs, Alfred Ernest ....Tunbridge Wells.
Hoblyn, Edward Robert.........Exeter.

Hodgetts, Nathaniel ....Birmingham.
Horn, Charles ....Hull.
Hyslop, Harry ....Stockport.
James, Taliesin ....Merthyr Tydvil.
James, William Montford ....Market Drayton.
Jaques, Arthur Stennitt.........Newcastle-on-Tyne.
Johnson, Edgar David ....Abergavenny.
Johnson, Frederick ....Chatham.
Johnstone, James...................London.
Jones, John Rothwell.............Ormskirk.
Keall, Charles Edgar ....Newcastle Emlyn.
Keinch, John Thomas.............Bolton.
Kendall, James William.........Whitehaven.
King, James, jun. ....Kilmalcolm.
Knighton, Tom.......................Staveley.
Lakeman, Nicholas Frank ....Modbury.
Langley, William Henry.........Nottingham.
Leadbeater, Sidney Herbert ...London.
Lee, Annie Mary ....Birmingham.
Lee, Richard Baxter ....High Ackworth.
Lewis, David Griffith ....Cardigan.
Lewis, Richard George ....Carmarthen.
Liggins, Thomas Pearson ....Putney.
Lillingston, Leonard William...Oxford.
Little, George ....Falkirk.
Littlefair, Thomas ....Shap.
Lockton, Frederic ....Grantham.
Loten, George William ....Hull.
Loveluck, Griffith David.........Taibach.
Lunn, Arthur ....Cambridge.
McAllister, William Frederick.Leicester.
MacBean, James Barnet.........Edinburgh.
McCulloch, Alexander............Elgin.
McLullich, James ....Kilmarnock.
Manfield, Robert Hall ....Pontefract.
Marshall, Daniel ....Bolton.
Maudson, Charles Frederick ...Leeds.
Mayne, James ....Carn Brea
Meldrum, Alexander ....Leith.
Miles, Ernest Blommart.........Worthing.
Miller, Alfred ....Chatham.
Moore, William ....Wisbech.
Morris, Edward Herbert.........Bedford.
Moulson, James Oglevie ....Bradford.
Newell, William Robert ....Southsea.
Newman, George Franklin......Portsmouth.
Norton, Frank ....Cheltenham.
Olds, George ....Farnboro' Station.
Onyon, Ellis Aitken................Lincoln.
Owen, William Lewis ....Llanon.
Page, Percy Dodson...............Boston.
Perren, Herbert Joseph ....Brighton.
Phillips, Daniel......................London.
Pinkney, William....................Middleton, Teesdale.
Poustie, James Henderson ....Alva.
Price, Peter ....Bromsgrove.
Pye, Alexander Greig ....Atherstone.
Quarmby, Thomas William......Market Drayton.
Ratcliffe, Samuel, jun.............Southport.
Reedman, Robert William ....Birmingham.
Rees, David Charles...............Ipswich.
Retallick, William Cyrus ....St. Austell.
Ritson, Robert Russell............Bolton.
Roberts, Edward William ....Wolverley.
Roberts, Robert ....Menai Bridge.
Roberts, William Arthur ....Bangor.
Robertson, John Wright.........Dundee.
Robinson, Frank Cole ....York.
Rodgers, Ivo Frederick ....Stafford.
Rose, Edgar ....Leamington.
Rowlands, Thomas ....Menai Bridge.
Rowles, Walter David.............Newbury.
Rowley, Frank........................Manchester.
Rutherford, Alfred E. Raif......Bristol.
Scobell, Herbert William ....London.
Scott, Henry ....Middlesborough.
Selby, Henry Collingwood ......London.
Shand, James Sellar ....Huntly.
Shaw Harry ....Wakefield.
Simpson, Peter ....Glasgow.
Smallman, Frederick Richard...Ludlow.
Smith, Edward Gibbs ....Walton-on-Naze.
Spafford, Henry John ....Hull.
Speechly, George ....Bishop Stortford.
Stebbing, Henry Fairhead ......London.
Stevenson, Alexander ....Kilmarnock.
Stevenson, Richard ....Atherstone.
Sumner, Henry Alfred ....Birmingham.
Swallow, Edward....................Stalham.
Sykes, Frederick John.............Halifax.
Thomas, Frederick Charles......London.
Thomas, William ....Cemaes.
Thorley, Walter ....London.
Thornton, George....................Mirfield.
Tiffany, Joseph.......................Mirfield.
Treharne, Charles Edward......London.
Turner, Ebenezer....................Whifflet.
Turpin, William ....Newcastle-on-Tyne.
Vargas, Santiago Inocencio......London.
Wadsworth, Edgar ....Huddersfield.
Wallis, William ....York.
Whitaker, William ....Accrington.
Whitehead, John Henry.........Leeds.
Whitelock, Richard ....Plymouth.
Wilson, Alexander ....Greenock.
Wilson, Kendrew John ....Thirsk.
Wippell, Alice Mary ....Perth.
Woodcock, Bertrand Joseph ...Newark-on-Trent.
Woodward, Albert Edward ...Lancaster.
Wools, Victor John.................Margate.
Wynter, Walter Robert ....Seaford.

The following is a list of the centres at which the examination was held, showing the number of candidates at each centre and the result:—

	Candidates.				Candidates.		
	Examined.	Passed.	Failed.		Examined.	Passed.	Failed.
Aberdeen	8	6	2	Lancaster	7	2	5
Birmingham	24	14	10	Leeds	29	12	17
Brighton	4	3	1	Lincoln	8	4	4
Bristol	8	4	4	Liverpool	8	3	5
Cambridge	7	3	4	London	58	24	34
Canterbury	3	1	2	Manchester	24	10	14
Cardiff	6	4	2	Newcastle-on-T.	11	4	7
Carlisle	12	7	5	Northampton	4	0	4
Carmarthen	13	8	5	Norwich	8	1	7
Carnarvon	6	4	2	Nottingham	14	6	8
Cheltenham	2	1	1	Oxford	2	2	0
Darlington	6	2	4	Peterborough	5	1	4
Dundee	8	5	3	Sheffield	5	2	3
Edinburgh	16	5	11	Shrewsbury	7	4	3
Exeter	15	7	8	Southampton	10	4	6
Glasgow	25	11	14	Truro	6	3	3
Guernsey	1	1	0	Worcester	5	2	3
Hull	6	4	2	York	9	5	4
Inverness	1	0	1				

The questions set for examination were as follows:—

Time allowed: Three Hours for the three subjects.

I. LATIN.

1. Translate into English:—

(i.) Omnibus rebus ad profectionem comparatis, diem dicunt, qua die ad ripam Rhodani omnes conveniant. (ii.) Hac oratione ab Divitiaco habita, omnes qui aderant, magno fletu auxilium a Caesare petere coeperunt. (iii.) Acriter utrimque, usque ad vesperum, pugnatum est. (iv.) Ipse interim in colle medio triplicem aciem instruxit legionum quatuor veteranorum, ita, uti supra; sed in summo jugo duas legiones, quas in Gallia citeriore proxime conscripserat, et omnia auxilia collocaret; ac totum montem hominibus compleri, et interca sarcinas in unum locum conferri, et eum ab his, qui in superiore acie constiterant, muniri jussit.

2. Decline *omnia auxilia* in the plural only, and give the genitive and dative singular of *unum locum*.

3. From what verb does *conferri* come? What part of the verb is it? Explain the construction.

4. Write out the present indicative of the verb from which *jussit* comes. Give the principal parts of this verb.

5. Translate into Latin:—(i.) He captured one of the sons of the general. (ii.) Cæsar was informed that the enemy was at hand. (iii.) On the tenth day we arrived at the town, which was being besieged by the Gauls. (iv.) The guides having already set out from the camp, we will follow them quickly.

II. ARITHMETIC.

[The working of these examples, as well as the answers, must be written out in full.]

1. A person buys 25 lambs for 915 fr. 25 c., and 30 more for 1420 fr. 75 c., and sells them at 43 fr. 5 c. each. What does he gain or lose? (Answer in francs, etc.)

2. What fraction must be added to

$$2\tfrac{1}{3} + \frac{3\frac{1}{3} - \frac{1}{6}}{3\frac{1}{3} + \frac{1}{6}} - 2\tfrac{5}{7} \text{ of } \tfrac{4}{19}$$

that the sum may be equal to 3?

3. Reduce $\cdot875$ of 17*s.* 6*d.* + $\cdot1\dot{6}$ of £1 8*s.* 1½*d.* to the decimal of £7.

If 30 men in 5 days build 100 yards of wall 5 feet high and 18 inches thick, what length of wall half as high again, and half as thick again, will 45 men build in 7 days?

5. A sum of money is divided between A., B. and C., in the proportion of 5, 7 and 9. B.'s share was 7½ guineas: find the others.

III. ENGLISH.

1. Give six instances of plural forms not ending in *s*, which occur in nouns of common use. State also from what languages such forms are respectively derived.

2. Give words formed by the following suffixes (one from each), and explain the force of each suffix:—*age, hood, kin, less.*

3. Parse fully—"Any pains that I take for you is as easy as thanks."

4. Write a short composition on *one* of the following subjects:—

(i.) The Fisheries of Great Britain.
(ii.) Modern Warfare.
(iii.) The Telephone.
(iv.) The Theatre.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

(*Continued from page* 312.)

In consequence of the great length of the next paper, an abstract of it was read by the author. The paper was entitled—

Remarks on Experiments with the Ointment Bases.

BY W. WILLMOTT.

An invitation to deal with the subject of ointments has appeared in the Conference List* for some time past. I beg, therefore, to offer the following remarks; not, however, as a complete answer to the question propounded in the invitation, but rather as setting forth the results of my own experience in this field of research.

Ointments and ointment bases have, it is true, already been much and ably commented upon; yet they are well worthy of further consideration and discussion; for although ointments have been called "barbarous" applications, and are, it must frankly be confessed, the reverse of pleasant or agreeable remedies, yet it is undeniable that they afford relief—and often great and curative relief—in some of the most painful and distressing maladies known to medical science. That an endeavour should be made, under these circumstances, to impart to such preparations the best qualifications for successful remedial use, together with the highest pharmaceutical perfection, seems sufficiently obvious. There are, perhaps, no remedies whether external or internal, which, pharmaceutically, will better repay any extra time or attention devoted to them; and yet, practically, there are none which, until within a comparatively recent date, have been so systematically neglected. To meet with an ointment entirely free from rancidity, and not discoloured or otherwise injured by age or keeping, was formerly rather the exception than the rule; but, happily, this is no longer the case, as, now, the best means are unceasingly sought for securing the very desirable qualities of efficiency and stability.

What, it may be asked, are the special points which commend themselves to our notice in a properly prepared unguent? They are chiefly the following:—colour, consistence, smoothness, neutrality, and freedom from rancidity, or from liability to acquire that condition. A word or two with reference to each of these may not be out of place.

Colour.—In the majority of instances the colour of a recognized official ointment is determined by the active ingredient with which it is mixed, and from which it takes its name. Thus, one ointment is red, a second yellow, a third black or brown, and so on, these colours indicating to some extent correctness of character and condition. On the other hand, there are ointments which are without colour (*i.e.*, distinctive colour), and where this is the case, it cannot be denied that an appreciative predilection finds its expression in the term "beautifully white."

As a point in connection with this much desired whiteness, we are directed by the British Pharmacopœia in nearly every case where the melting process is adopted in the preparation of an ointment, to stir constantly until cold, or until the mixture solidifies. This constant stirring is undoubtedly important, although, perhaps, on account of its tediousness it is seldom strictly carried out. It is well known, that by the beating, whipping, or stirring of colourless mixtures of fatty substances, more or less whiteness and lightness are secured, the effect being produced by what has been called "the molecular interposition of the atmospheric air." By this means also smoothness and softness are promoted, and the "beauty of the product" is correspondingly enhanced.

Consistence.—In practice the consistence of an ointment is essential to its proper application. If too soft it is not well adapted for surgical use, and if too firm it lacks the quality necessary for the anointing of inflamed surfaces, etc. It is desirable, therefore, to have at command one or more bases fulfilling each of these conditions, so that the requirements of both surgical and medical practice may be fully met.

Smoothness.—The quality of smoothness in an ointment scarcely needs comment. All will agree with Professor Redwood, that the presence of hard particles therein is very objectionable, and indicates want of skill or of careful attention in the dispenser.

Neutrality.—By neutrality is indicated that condition in the basis which leaves it without medicinal action of any kind. This condition is of essential importance, whether such basis be employed for the conveyance of active agents, or simply as a means of excluding the air. What is required is a non-irritant in the strictest sense of the term.

Freedom from Rancidity.—That ointments should be free from rancidity is a self-evident proposition, and one, moreover, which is conceded by all. Any substance, therefore, which is not liable to change by keeping must perforce possess a special value for the pharmacist, and it is simply stating a truism to say, that in all recommenda-

* "Subjects for Papers."

tions of particular substances to be used as ointment bases this quality of resistance to oxidation is more or less enforced: it is, perhaps, the standard by which we may best estimate the relative value of the several bases which from time to time have been, and are, employed in the making of this useful class of preparations.* The tables given in this paper are directed more especially to this end.

To meet the several requirements thus enumerated, we have in reality but few substances known as bases, either simple or compound. These may really be said to be but three in number, viz., lard, oil and wax, and the mineral hydrocarbons. Many "substitutes" of value and merit have been proposed, such as glycerine in combination with starch, and with fuller's earth; pigmentum album, honey, glycelæum, shea butter, the oleates and oleo-palmitates, and so forth; but as none of these, although well meriting the fullest attention, have come into extensive use, they need not in this contribution be further referred to.†

Of the three above-named bases, lard has hitherto been the most generally available, and though it may be thought an advantage if, on account of its proneness to change, it could be dispensed with entirely in connection with pharmacy, it is evident that in view of our present requirements this cannot be done.

It will be my endeavour, therefore, to show the relative value of this substance as compared with that of oil and wax, and the petroleum residues, and this, I think, will be most clearly made manifest by stating results in the form of a series of tables which for the most part will speak for themselves. It may be premised, that as regards the therapeutic action, if any, of these three bases, there is, in reality, nothing to choose between them. Given pure and well-conditioned products, and all are equally applicable for external medication.* At the same time to ensure this result careful preparation in each instance will be found necessary. How is this best to be accomplished in the case of lard, the basis which we have first to consider?

The simple plan is, of course, melting and straining; but, besides this, two processes of a somewhat special character have been introduced. One, that of the Pharmacopœia, which may be described as a process of washing and straining, and the other that of Mr. Edward Smith, which, in addition to washing, insists upon *filtering* as a *sine quâ non*.† Both these processes are excellent in theory, but, truth to say, possess no advantage in practice. The washing on the one hand and the filtration on the other, involve conditions which appear to counterbalance any advantages which may result from their adoption. Much decomposable matter, it is true, is removed in the process of washing as directed by the Pharmacopœia;‡ but the heat required subsequently to get rid of the water is prejudicial to the stability of the product. In Mr. Smith's process, also, the sustained temperature necessary for filtration, though not greatly above 100° F., seems detrimental to the keeping properties of the lard so treated;§ whilst the removal of all traces of water by the plan proposed by that gentleman, is scarcely so easy of accomplishment as his description would seem to imply. It must, indeed, be conceded, that both processes give unexceptionable products as prepared specimens; but it still remains, that the pure article of commerce, which may be purchased in any quantity, is sold, not as "Pharmacopœia" lard, or as "filtered" lard, but simply as a "clarified" preparation.‖

The following statement will show the extent of stability of lard when subjected to different methods of treatment:¶—

ADEPS PRÆPARATUS.

No. 1. Bladder lard	Rancid within 18 months.	
No. 2. Ewens's "pharmaceutical"		
No. 3. Ewens's "pharmaceutical," filtered		
No. 4. Ewens's "pharmaceutical," benzoated	Rancid within 5 years.	
No. 5. "Flare" melted and strained	13 months.	Good.
No. 6. "Flare" melted and filtered		Good.
No. 7. "Flare" washed and strained (B.P. process)		Rancid.
No. 8. "Flare" washed and filtered (Mr. Smith's process)		Slightly rancid.

Taking now Nos. 5, 6, 7 and 8 as having been under observation *ab initio*, and testing them in the form of ointments, two of which are of all others the most liable to rapid deterioration (and for this reason frequently used in these experiments as a test of stability in the basis), we find results of a corresponding character to the above. See Table at top of p. 332.

It would appear, therefore, that washing and straining, or washing and filtering, necessitating, as they do, a more or less sustained temperature of 100° to 212° F., are without advantage in the preparation of lard for use as an unguent basis. On the contrary the best results seem to rest with the simple process of melting and straining. But, in any case, the condition of rancidity in lard is soon developed. This, however, is obviated to a very large extent by the use of benzoin, and from the marked preference given to "benzoinated lard" in the United States Pharmacopœia (the new edition), to the entire exclusion in the ointment series of the mineral hydrocarbons, as well also as from its adoption by our own authorities, it may be assumed that this well-tried basis (viz., lard), whether plain or benzoated, is still considered by physicians and pharmaciens of the day an essentially valuable ingredient in pharmaceutical manipulation. In a tabular statement presently to be given,

* "One of the most, if not the most, important points in the making of ointments is that they should be so prepared as to keep as long as possible without becoming rancid."—A. F. Haselden, *Pharm. Journal*, December 1, 1863.

† A specimen of Mr. Schacht's "Plasma" (Glycerinum Amyli) prepared February 27, 1879, and preserved in a stoppered bottle, is, at the present date, absolutely perfect.

* A suspicion, not altogether groundless, exists with regard to the petroleum residues, that they are the source of considerable mischief in a certain percentage of severe cases. As a question of preference there could not, perhaps, be a better unguent basis than *oil and wax*; and regarded as a soothing admixture of this character, the "unguentum cetacei" of the London Pharmacopœia, composed of olive oil, wax, and spermaceti, may be said to be wholly unsurpassed.

† 'Proceedings of the British Pharmaceutical Conference,' 1869, p. 26.

‡ As an experiment portions of the water so used were *filtered quite bright* and set aside. Within four days decomposition had commenced, and at the completion of a week, all the specimens were in a thoroughly bad and offensive condition.

§ "I believe the secret of making good sweet lard depends upon the small quantity of heat employed in the melting."—A. F. Haselden, *Pharm. Journ.*, December 1, 1863.

‖ Mr. Ewens informs me, that his "clarified" lard is invariably *washed*, and certainly, like the Pharmacopœia product, it is a white, smooth, and most excellent preparation; but the question remains, is prepared lard, in consequence of washing, less liable to rancidity than that which has simply been melted and strained? My experience seems clearly to indicate that it is not.

¶ Owing to the pressure of other work, more detailed observation could not be made. This applies also to the remaining tabular statements, which, in consequence thereof, are not given in quite so complete a manner as could be wished.

OIL AND WAX.*

The ointment basis formed by the combination of oil and wax may be considered to include all those artificial mixtures of fatty substances of which the "simple ointment" of the British Pharmacopœia is the representative. The advantage of such a basis is, that any consistence can be obtained, from the firmness of a cerate to the softness and thinness of oil itself. As a simple application for wounds or inflamed surfaces, this very useful combination possesses a purely negative, though essentially protective effect. The one objection is, as in the case of lard, the liability to become rancid, though, if yellow or unbleached wax be used, a very permanent condition is secured. A careful review of the following statement will show this to be the case:—

The unbleached wax imparts colour, and also a pleasant odour, and hence, perhaps, its very stable character. If *whiteness* be an object, this substance in its unbleached state, cannot, of course, be used.* The behaviour of oil and wax as a basis for the official ointments is given a little further on.

THE MINERAL HYDROCARBONS.

The introduction of the mineral hydrocarbons for the purpose of external medication has brought with it many changes in some of our accustomed formulæ. These mineral substances are said to be antiseptic in their effect, and as a chief recommendation it is strongly claimed for them that they are free from the objection which obtains in the case of the two bases we have been considering, viz., liability to change by oxidation. The names given to these hydrocarbons are well known to us as cosmoline, fossiline, ozokerine, vaseline, etc., the "ine" being a popular and euphonious affix which has of late been somewhat indiscriminately applied. It is not my intention to determine the *inclusive* merits of these several substances, but I give in tabular form the results of my observation, the comparison showing quite an appreciative difference in their behaviour when time has been allowed to exercise full influence over them. One important drawback to vaseline, to which preference in practice has heretofore been given, is its liability to develop a strong petroleum-like odour, which is scarcely less objectionable than actual rancidity. Melted with paraffin, white wax, or spermaceti; and especially with paraffin, or in the presence of carbonate or acetate of lead, this odour is strongly developed. In combination, however, with *yellow* wax, it is entirely prevented.† On the other hand, the palm must be awarded to vaseline for the retention or preservation of its original colour.

Objections have been entertained to the above mineral products on the ground of their great softness. "We want," said a physician to the Hospital for Diseases of the Skin, "an ointment not a liniment." It is, of course, quite competent to add wax, paraffin, or spermaceti in any quantity that may be desired, but this may be thought both troublesome and inconvenient, as, in the absence of a certain requisite amount of physical labour, there may result a want of that smoothness which is so desirable in a basis of this character.

* The colour of yellow wax mixed to form a simple basis, remains unimpaired after many years.

† This pungency or rankness, which, in the absence of chemical examination, has been assumed to arise from the presence of traces of crude petroleum, and, hence, so described, is developed to some slight extent in ozokerine, but not at all, under any conditions, in either fossiline or "chrisma," a circumstance which imparts to these latter an advantage deserving of the fullest consideration.

VASELINE, FOSSILINE, OZOKERINE, AND CHRISMA.

(*Length of trial*, 2 *years*.)

Unguent.	Vaseline.	Fossiline.	Ozokerine Alb.	Chrisma.
Ung. plumb. acet.	Strong petroleum odour. Transparent oily separation on surface. Colour good.	Odourless. Soft. Dark mahogany colour. Opaque muddy appearance.	Slight odour of petroleum. Very soft and oily. Somewhat transparent in appearance.	Similar to fossiline, but decidedly the better of the two.
Ung. plumb. carb.	Powerful petroleum odour. Oily layer on surface. Colour light.	Free from odour. Orange yellow colour uniform throughout.	Colourless. Very soft. Entirely free from rock oil odour.	Colour a little lighter than fossiline. Slight separation of oily globules below surface.
Ung. hyd. ox. rub.			Colour bright. Very soft. Honey-combed appearance beneath surface.	

Note.—From whatever source fossiline and chrisma are derived, the two appear to undergo similar treatment in their production and preparation.

VASELINE,* WITH PARAFFIN, WAX, AND SPERMACETI.

(*Length of trial*, 3 *years*.)

Unguent.	Vaseline 2. Paraffin 1.	Vaseline 2. Cera Alb. 1.	Vaseline 2. Cera Flav. 1.	Vaseline 2. Cetaceum 1.
"Cerat. petrolei."	Very appreciable rock oil odour. Slightly granular appearance. No change of colour.	Waxy consistence. Opaque. Slight paraffin odour. Colour unchanged.	Pleasant smell of beeswax. Firm, good consistence. Smooth and uniform throughout.	
Ung. plumb. carb.	Rank, disagreeable odour. Dark on surface, light beneath. Good consistence. Smooth.	Similar to vaseline and paraffin, but of uniform light yellow colour.	Odour of beeswax. Good in all respects.	Similar to vaseline and cera alb., but preferable in appearance.
Ung. hyd. ox. rub.	Uniform bright colour. Granular appearance. Quite perceptible rank odour.			Similar to vaseline and paraffin, but less granular in appearance. Soft consistence.

Whichever of the hydrocarbons or their respective "cerates" may be selected for adoption, it is at least a fair opinion, that they cannot be credited with improving the appearance of the pharmacist's stock. Not unfrequently they produce granular, greenish-looking, oily compounds, which have nothing about them calling for a just appreciation of their real merits. If "a good appearance is the first letter of recommendation," we certainly do not find here the full value which the trite sentiment conveys.

I must here specially notice a particular preparation of this class known as "white ozokerine," or ordinary ozokerine "made absolutely white," on the very plausible assumption that it would be "more appropriate to its purity and suggestive of its virtues." It is described as "a pure hydrocarbon, with formula $C_{85}H_{13}$, or thereabouts, obtained in the distillation of the solid paraffin ozokerite, and analogous to the new American substance vaseline." My attention was enlisted on behalf of this speciality by the following letter from Professor Bloxam, of King's College:—

"Dear Sir,—Will you kindly allow me to introduce to you my friend Mr. Edmund Field, who desires to submit for your consideration a new preparation, white ozokerine, which is, from a chemical point of view, all that could be desired as a simple cerate or unguent.

"Very faithfully yours,
"C. L. Bloxam,
"*Professor of Chemistry*, K.C.L."

In accordance with this request I subjected the sample left in my hands to a sufficiently severe test in the form of the red oxide of mercury, and carbonate and acetate of lead ointments, and the result, so far as the comparatively short period at my command would allow, was satisfactory. As against vaseline it fairly held its own, and, like vaseline, far out-distanced in durability of condition the mixed basis of oil and wax. This result is clearly shown in the following table:—

* Vaseline is here used as being the most familiar of this class of preparations.

VASELINE, OZOKERINE, AND OLIVE OIL, WITH CERA ALB. AND CERA FLAV.*

(*Length of trial, eight months*).

Unguent.	Vaseline and Wax.		Ozoker. Alb. and Wax.		Olive Oil and Wax.	
	Vaseline 5. Cera alb. 1.	Vaseline 5. Cera flav. 1.	Ozok. alb. 5. Cera alb. 1.	Ozoker. alb. 5. Cera flav. 1.	Ol. Olivæ 5. Cera alb. 1.	Ol. Olivæ 5. Cera flav. 1.
Ung. simp.	Slight petroleum odour; otherwise good.	Good in all respects. Pleasant smell of beeswax.	Odourless. Uniform bluish-white tinge.	Similar to vaseline and cera flav.	Good. Better in appearance than the petroleum specimens.	Similar to ol. olivæ and cera alb.
Ung. plumb. acet. .	Strong rock oil odour. Colour light below surface. Smooth and transparent.	Colour indifferent. Pleasant odour of beeswax.	Indifferent. Dirty bluish tinge. Odourless.	Similar to vaseline and cera flav., but lighter in colour and less transparent.	Badly rancid after six months, the change commencing within five weeks.	Similar to ol. olivæ and cera alb. Dark, dirty appearance.
Ung. plumb. carb. .	Paraffin odour. Slight separation of oily globules. Smooth. Colour not uniform.	Similar to vaseline and cera alb., but free from paraffin odour.	Odourless, and in all respects good.	Good in all respects. Pleasant odour suggestive of perfume.	Rancid within six months. Clean and white throughout.	Fairly good after six months, but rancid within eight months. All colour lost.
Ung. hyd. ox. rub. .	Colour good. Odourless.	Good in all respects.	Colour good. Odourless.	Good. Faint hay-like odour, suggestive of perfume.	Rancid. Colour changed on surface.	Similar to ol. olivæ and cera alb.

White ozokerine has the merit of being free from colour; but it is too soft for general use without the admixture of some solid fatty substance, such as wax or paraffin. In this form I shall have occasion to speak of it again before concluding my paper.

As a fair test of the stability, and, therefore, to this extent, of the relative value of the three bases herein adopted for consideration (which, as we have seen, are those readily available for use and now commonly employed in practical pharmacy), six of the official ointments were each carefully prepared with different varieties or sub-classes of such bases (making forty-eight specimens in all), and on examination at irregular, and, through pressure of work, sometimes long intervals, gave the results shown in the table on the opposite page. I may add, that the process of oxidation in fatty substances being slow and insidious in its progress, the change is not easy of detection at its commencement.

The prominent feature in this table is the great superiority of unbleached wax and olive oil, and the permanence of the mineral hydrocarbon vaseline, always excepting the development of the objectionable odour peculiar to it, which appears to be due to the particular process employed in its preparation; a process which is claimed as being exclusively applied to this variety of the petroleum residues.

It will be observed, that in these trials all the lards gave way early, with the exception of the "benzoated," which, in the presence of lead and mercury (a severe test), retained its soundness for something like twelve months; whilst ung. zinci and ung. gallæ when benzoated were found in an almost perfect condition at the end of four years. Benzoin, though a powerful preservative of fatty substances, should, perhaps, be introduced into these preparations as sparingly as possible, since in special, though it may be exceptional, cases, owing to the local irritation which might possibly be set up, the intended good may be counterbalanced by more or less avoidable mischief.

Attempts to mix the petroleum residues with lard and oil of almonds, etc., on the ground of the supposed antiseptic properties of the former, were not successful. Equal parts of lard and vaseline became badly rancid within two years; and, similarly, different proportions of oil of almonds with white wax and ozokerine, or vaseline, all gave way either sooner or later. A largely preponderating proportion of the hydrocarbon would be required to prevent all change in semi-solid, oleaginous mixtures of this description. When these mixtures contain lead or mercury decomposition sets in very quickly. A few examples may here be given:—

Ung. Plumb. Carb.

Bases.	Ozokerin 3.	Cera alb. 2.	Ol. amygd. 1	All rancid within four months.
	Ozokerin 3.	Cera alb. 2.	Adeps 3	
	Ozokerin 1.	Adeps 3.		
	Vaselin 1.	Adeps 3.		
	Paraffin 2.	Adeps 3.	Ozokerine 3	

Substituting mercury for lead, the above experiment was repeated with precisely similar results, rancidity commencing in both instances within three or four weeks from the date of preparation. In the single specimen of the second group in which lard was absent, the colour of the red oxide (the preparation used) was found bright and perfect at the end of fifteen months.

These "remarks" would scarcely be complete without a brief allusion to three specially prominent ointments which have proved very troublesome, and, it may be added, unsatisfactory, to the working pharmacist. The first of these is the diachylon ointment of Hebra. It might be quite worth while to consider the exact conditions of success in the process of boiling together water, oil, and oxide of lead, if it were not that we have in the petroleum hydrocarbons so good an agent for removing all difficulties out of the way, and insuring the most complete success. Made with

* Vernacular terms and medical Latinity are used in all cases arbitrarily as suggested by convenience.

EXPERIMENTS WITH OFFICIAL OINTMENTS.

Explanation.—Where there is no rancidity the term "good" is used; whilst *degrees* of rancidity are, as far as possible, indicated by the terms "slightly," "quite," "very," and so on.

N.B.—In all cases rancidity goes from bad to worse; so also the rank odour developed in vaseline.

Note.—The exact condition, as regards soundness, of Ung. Gallæ in the above, was very difficult to determine.

equal parts of one of these prepared petroleum residues and lead plaster, the result is satisfactory in every way, and an excellent unguent is certainly, and in the easiest possible manner, obtained. The plaster should be recently prepared, and the minimum of heat employed in melting it down. Very little stirring will be needed while the mixture is cooling. I have had under observation three specimens of this ointment which were prepared on June 20, 1879, *i.e.*, more than four years ago. No 1 was made with vaseline; No. 2 with chrisma; and No. 3 with ozokerine. As a result the colour is best maintained by the vaseline—a property of this substance already referred to—the fine odour of the oil of lavender is by far the best preserved by the chrisma (formerly called ung. petrolei); whilst the ozokerine specimen, without being very bad, is decidedly inferior in both these respects to the other two. All are more or less granular and lumpy; the chrisma preparation, however, being the least so of the three. Made with *olive oil* and lead plaster ung. diachyli becomes rancid within a few months.

The second of the three ointments claiming a brief notice is that of boracic acid, frequently called "boric ointment." This, as is well known, was introduced by Professor Lister, of King's College Hospital. The original formula for the full strength runs precisely as follows:—

℞ Acidi boraci,
Ceræ albæ . . . . āā ℥j.
Paraffin,
Ol. amygdalæ. . . . . āā ℥ij.

Melt the paraffin and white wax together, add the almond oil, and mix well; then add the boric acid finely levigated and *stir well till cool.*

Divide the mass into small pieces and then bruise and mix well in a mortar.

Sig. Boric ointment full strength.

When well managed *secundum artem* this formula yields a "beautifully white" product, both smooth and firm. It was a special favourite in the practice of the late Dr. Tilbury Fox, and was the more appreciated as it left no glistening layer of oil or grease on the surfaces to which it was applied. It was found, however, that its proper condition could not be depended upon for more than a few months, and this being so, a new basis composed of vaseline and paraffin, for which we are indebted to Mr. Martindale, was submitted for authoritative approval, and, having received full assent, was thenceforward substituted for the wax and oil. This basis, "cerat. petrolei," except that it sacrifices appearance to utility, successfully resists all change for a considerable time; not, be it said, indefinitely, for ultimately (*e.g.* within three years) the rank odour peculiar to vaseline, and already fully commented upon, becomes freely developed. If, being a mineral product, it is necessary to use solid paraffin to the exclusion of yellow wax, probably chrisma or white ozokerine may be advantageously substituted for the vaseline; though, here, it will be necessary to give full consideration to any difference in effect resulting from their use which experience may point to as a possible or probable contingency. It will be noted that in the above formula we are especially instructed to "stir till cool." The subsequent labour, however, of reducing to smoothness will be considerably lightened (*i.e.*, in the case of the basis itself which might be first completed) by allowing the mixture to cool *without* stirring; and, obviously so, as in such a case the paraffin, regardless of its high melting point, will be uniformly and perfectly distributed through the mass, and thus made easily manageable under an ordinary palette-knife. I may say, that for the smoothing process the pestle and mortar is of very little use; what is required is a large marble slab presided over by a zealous operator not sparing of his labour. Prepared thus boric ointment forms a very efficient application, and is largely prescribed both in private and hospital practice.

Lastly, then, I have to notice the almost played-out, but ever-diversified and perplexing unguentum hydrargyri nitratis. I refer to this chiefly because a new theory of its early deterioration has been propounded by Mr. Maben namely, that the reduction of the mercury is caused (and, we must presume, solely caused) by the action of some foreign oil added to the olive oil as an adulterant.* There can be no doubt, I think, that the oil is the chief agent in the production of this change when consideration is had to the quantity of nitric acid with which it is in part combination; but I should prefer to regard it rather as a question of degree between the olive oil on the one hand, and the foreign oil on the other, than as a question of change with the latter, and no change at all with the former. It will be convenient to adopt the hypothesis, that various oils possess in different degrees, in the presence of heat, the power of breaking up the nitric acid, and that this power is possessed by olive oil to a comparatively small extent only. A larger proportion of acid being thus retained in its normal condition, the reduction of the mercury is for the time being prevented.† But still less is this power possessed by lard alone, for here, so far as my observation extends, there is no subsequent deterioration in point of colour whatever, and to this extent, perhaps, the U. S. formula is a step in the right direction. It must not be overlooked that Mr. Maben's position is strengthened, or apparently so, by the circumstance that in heating a specimen of ointment prepared with pure olive oil to 300° F., he found no change of colour. This test, however, is scarcely sufficient. A better one would be to take a somewhat lower, though increasing, temperature, and prolong it for fully half an hour. If this be done, I think it will be found, that in spite of the pure olive oil the ointment will change to a deep brown, and an unmistakable layer of mercurous oxide will be deposited in the containing vessel. I have spoken of the quantity of nitric acid ordered for use. It is well worth noting that if this be increased to three-fifths of the weight of the oil and lard combined, all change is prevented, a circumstance which is very significant as regards the prominent influence exercised respectively by the acid and the oil. Allowing full weight to the latter, the conclusions arrived at by Mr. Schacht, from able experiments conducted many years ago, appear to retain their validity to the present time.

A word as to temperature. Mr. Maben reflects on the authors of the Pharmacopœia for their indefiniteness on this point, whilst he himself is sufficiently obscure in the same direction. The expression "heated to" is clear enough, but "prepared at" is, here, not quite so obvious. What does Mr. Maben mean by the ointment being "prepared at" 180°, 212° and 300° F.? The truth is, this ointment cannot be *prepared* (which, of course, includes the entire process) at any given temperature. What really occurs (and I am not aware that any writer has yet drawn attention to the point) is this:—Supposing the temperature to be kept below 180° F., there is no frothing, but the process proceeds very slowly for several days, and the ointment so prepared is of soft consistence and very light in colour. If the mercurial solution be added to the oil and lard heated in a water-bath to

* Vide *Pharm. Journ.*, April 21, 1883.

† In reproducing Mr. Maben's experiments, I did not get precisely similar results; for instance, the 10 per cent. rape oi admixtures produced excellent ointments at both temperatures, the bright yellow colour being fully retained to the present time. Using *rape oil alone* with the acid solution mixed at 212° F., the colour was also good, but changed to greenish yellow within three weeks. In this latter case the action was more energetic and the temperature attained slightly higher than when pure olive oil was used. This would seem to indicate greater disturbance of the nitric acid, and, as already intimated, may furnish a sufficient reason for its being more readily parted with. The rape oil specimen was soluble in ether similar to Mr. Maben's "B" experiment with the pure oil.

180° F., there is but little change for the moment; but when the temperature reaches 200° F., or a degree or two higher, frothing commences, and the heat then rises with comparative rapidity to 255°–65° F., as the highest frothing point. Assuming now that the solution is added to the oil and lard at 212° F., the effervescence begins at once, and the mercury then runs up, as in the former instance, to 265°–70° F., a difference only of about 5 degrees in the two cases. With the acid solution mixed in at 300° F., the action is so energetic that the heated liquid is thrown violently out of the vessel, and all around, to the dismay and very probable discomfort of the operator. Under these circumstances, the directions of the Pharmacopœia appear to be sufficiently definite, inasmuch as they secure the frothing up of the mixture, and its consequent exposure to the influence—whatever that may be—which at least 250 degrees of Fahrenheit may have upon it.

Whilst on the subject of "citrine ointment," it may be useful to refer to a troublesome feature in connexion with its admixture with lard to form the Ung. Hyd. Nit. Mitius of the London Pharmacopœia. It is well known that "citrine ointment," especially when recently prepared, cannot be so mixed without quickly acquiring a leaden hue, owing to the rapid reduction of the mercury. To the pharmacist who is attached to his work, and who conducts his processes *con amore*, this is simply intolerable. The difficulty, however, may be met by adding to each ounce of the lard from 10 to 30 minims of peroxide of hydrogen, or ozonized ether. This is both harmless and efficient, but it has the disadvantage of developing in the ointment a sharp pungent odour something approaching to rancidity. Fortunately a still better remedy is at hand, viz., the mixture, before referred to, of ozokerine. alb. and white wax. This appears to be the only substance which successfully resists the change alluded to. Paraffin cannot be used, vaseline is altogether unsuitable, and yellow wax of course imparts colour; but white ozokerine and white wax—2 parts of the former and 1 of the latter—prepared *s. a.* and reduced to perfect smoothness on a marble slab, together form a basis applicable not only to the above, but to a number of small things in the pharmacy of a similar description where the absence of colour and the presence of permanence and stability are especially to be desired.

It remains only to state that I have endeavoured in this contribution to avoid all needless technicality, and to confine my remarks to a simple and unvarnished statement of personally observed facts, as viewed from a pharmaceutical standpoint of present and progressive utility.

The PRESIDENT said a special vote of thanks was due to Mr. Willmott for his intelligent and patient work, now extending over several years, and for this paper, which was full of interest to every pharmacist.

Mr. WILLIAMS asked whether the white wax referred to was that usually employed in pharmacy, or what he should call white wax, because they were very different things. The white wax of pharmacy was understood to contain about two parts to one of spermaceti.

Mr. WILLMOTT said he endeavoured as far as possible to carry out his experiments with the materials usually used in the pharmacy. There were very few cases where special kinds of wax would be obtained, and, therefore, he used the ordinary ingredients.

Mr. MASON said he presumed he referred to the ordinary round cakes of commercial white wax.

Mr. WILLMOTT replied in the affirmative.

Mr. WARD (Leeds) asked if Mr. Willmott had made any examination of the different kinds of hydrocarbons known under different names in order to prove their identity or otherwise. There were several of these articles presented under different names, and if it could be determined that they were substantially all of the same composition it was very desirable that that should be known.

Mr. WALTER HILLS asked if Mr. Willmott had made any experiments in the bleaching of white wax, or did he consider that the somewhat unpleasant odour which attached to white wax was unavoidable. He had often thought that if white wax could be obtained as pleasant in odour as yellow wax it would be very important. The vaseline basis and the lard basis might be used for very distinct purposes, as had been shown by Mr. Martindale, vaseline being more suitable for external application as a kind of shield, whilst lard was more suitable where absorption was required.

Mr. MOSS wished to express his obligation to Mr Willmott for the extremely useful manner in which he had handled this subject. He should have been glad if Mr. Willmott's conclusions had been somewhat different, because they combated some conclusions of his own, particularly with reference to vaseline. Mr. Willmott's main conclusion appeared to be that vaseline was not so unalterable as it had been stated to be, and not so good as several other ointment bases to which he had referred. Some few years ago, being then somewhat identified with vaseline, he (Mr. Moss) had made experiments, embracing all the ointments in the Pharmacopœia, and in no one instance did he find the petroleum odour become developed. He should like to ask whether Mr. Willmott made all his experiments with the same sample of vaseline, because it was just possible that one specimen might not be so thoroughly purified from those paraffins which were associated with it originally. With regard to the composition of vaseline and ozokerine, they were both hydrocarbons, but differed physically to a considerable extent, which he was quite unable to explain, save that they came from different parts of the world, and had stamped on them certain impresses which were not recognizable by chemical means.

Mr. NAYLOR asked in what manner the initial stage of rancidity was ascertained. He also was a little disappointed with the conclusions arrived at, his own experiments being quite confirmatory of the results just stated by Mr. Moss. That might be accounted for by the fact that his experiments were all made at the same time as those of Mr. Moss, and he believed from the same specimen of vaseline. With reference to the composition of these hydrocarbons, he had examined five or six, and the only real difference between them was that while they all contained hydrocarbons of the same series they belonged to different parts of the series.

Dr. SYMES said he could to some extent confirm the statement made by Mr. Willmott, that vaseline did not always retain after keeping the freedom from odour which it possessed in the first instance. Some seven years ago, when vaseline was not so well known, he put up a glass jar containing a specimen of it in his pharmacy, where it could be seen by medical men. A gentleman present at that meeting, happening to come in, took the lid off and remarked that it smelt quite acid. He forgot to remove it, and the specimen remained, until one day the representative of the proprietors of vaseline entered his pharmacy, and it occurred to him to call his attention to it. Had it not been that the specimen came from a highly respectable house the genuineness of the specimen would have been doubted by Mr. Chesebrough, and, in fact, he did express doubts about it. It was not so much the smell of petroleum as of some acid, and he thought probably in the treatment with nitric acid in the process of purification some decomposition product had remained. His experience differed somewhat from that mentioned, that these hydrocarbons did not tend to preserve substances like lard. He found, as a matter of experience, that the admixture would keep better than lard, or a mixture of oil and wax alone. There appeared to be two classes of these bodies in the market, one, petroleum jelly obtained in purifying crude petroleum, holding a place between lubricating oil and paraffin wax, which had never been in a crystalline condition, and was, therefore, soft and emollient in character, and another, being that which was prepared by dissolving a soft paraffin having a low melting point in lubricating oil. These would possess different characteristics; one, being more or less crystalline, and although harder in the first instance, when broken up was quite as soft as the jelly-like body, but the two would always have distinct characteristics. He had hoped that Mr. Willmott would have made some experiments with the process recently proposed for preparing a substitute for ointments, by a solution of gelatine containing a small quantity of glycerine. He had tried it in the preparation of active remedies, such as chrysarobin, and it answered very well, retaining its consistency when painted on the skin. He thought a compound of that kind might usefully replace some of the ointments which were likely to change.

Mr. Pickard asked if Mr. Willmott had made any experiments with the white vaseline lately introduced. The presumption would be that the white would be the purer of the two. The yellow, when heated, certainly gave off a petroleum odour; but he did not think the original samples did so much as those he had seen since. He should also like to ask Mr. Williams if what was commercially known as white wax was not in large blocks.

Mr. Williams said the wax he alluded to as pure was not known as block wax, which he believed contained other materials. It was wax which was largely used by dentists, who required to have it free from spermaceti; it was also used by photographers, and it professed to be pure beeswax, bleached.

Mr. Frazer said he had used the wax referred to for some years, and it was known as dentists' wax. It was made by Field and Co. and other large houses, and was quite different from the ordinary white wax.

Mr. A. H. Mason remarked that what was referred to as block wax was known in the trade as Madras wax. It was not at all necessary to use manufactured or bleached wax in the preparation of ointments. Those who were in the habit of manufacturing furniture polish were aware that ordinary white wax in cakes was not at all suitable for the purpose, the Madras wax being far preferable. He should like to ask if Mr. Willmott had made experiments relative to the colouring properties which vaseline and other hydrocarbons seemed to possess. Complaints were often heard that pomades or ointments made with them stained the skin or the linen, and he wished to know whether it might be due to a difference in the hydrocarbons, or in the case of pomades to physiological action, the colouring matter in the hair yielding to them and the pillows becoming stained. He knew a case of a lady in Paris who had used some pomade prepared with one of these bases; she had white silken hair, of which she was very proud, but after using this pomade for a few days her hair became a disagreeable yellow colour.

Mr. Conroy said, that his experience of the preparation of lard totally differed from Mr. Willmott's; he found that by filtration he got a most excellent product which would keep good and sweet. He did not consider washing to be of much use, but careful filtration was necessary to separate decomposable matter, and he had never found any difficulty in separating water after washing, because by allowing the lard to rest a few minutes, the water would sink to the bottom. There was no necessity for any length of time to be occupied in the filtration, as at a temperature of about 200° F. it would easily run through filtering paper. With regard to the petroleum odour developed by hydrocarbons, though he had prepared a great many ointments with these bases, he never noticed any development of this odour, though they certainly all developed what might be called a rancid smell, and that was developed more quickly when they were exposed to strong sunlight. He was not surprised to hear that when peroxide of hydrogen was added to an ointment it became rancid, for if he wanted to produce such a result it was just what he should do. One frequent complaint with regard to vaseline and other hydrocarbons was that they produced irritation of the skin, and he had seen children's arms in a very bad state, arising as stated by the medical man attending the case from the application of hydrocarbon jelly.

Mr. Holmes trusted that Mr. Willmott would continue his researches until he had arrived at the means of making a white ointment which would not turn rancid. He had recently seen a vegetable fat sent from Singapore, which was called vegetable tallow, and it was said never to turn acid. When it was obtained white, which was not very often, he understood, it made a very good ointment simply with the addition of a little olive oil, and if there were any demand for it, he thought there would be no difficulty in obtaining a supply. He had seen some of the seeds from which it was obtained, and as they were not recognized either at Kew or the British Museum, it was obvious they were not yet known to commerce. He had a small quantity of the fat which he could place at the disposal of Mr. Willmott if he would like to experiment with it.

Mr. Conroy asked if shea butter was the same thing as vegetable tallow, and if Mr. Willmott could give any information about it, particularly as to whether it had any medicinal properties of its own.

Mr. A. C. Abraham wished to dispel an idea which might arise from what had been said, that pure white wax was only used in Scotland; it was easily obtained by anybody who wished to get it. He had always used it and believed that the firm to which he belonged had used it for as long a period as had been named (forty years). With regard to Mr. Williams's suggestion that the difference noted by Mr. Willmott was possibly due to the quality of the wax rather than to its having been bleached, his results, working with pure wax, quite bore out what Mr. Willmott had said, and the fact that white wax was oxidized by exposure to the air would lead one to expect such a result.

Mr. Ward said it would be well if it were explained whether English or foreign yellow wax was referred to.

Mr. Woolley said it was very desirable that Mr. Willmott should continue this investigation, especially with regard to the wax question, as if he had used round cakes probably his results would require reconsideration. As regards Madras wax, the purity of a great deal of that was open to considerable doubt. The whole question of the wax to be used in ointment making might with considerable advantage be investigated further. It was rather surprising to him that one very simple thing was omitted in Mr. Willmott's paper, namely, the first preparation of the lard. He had mentioned bladder lard, but it was a very simple process to take the flake lard, and having properly bruised it so that all the vesicles were broken up, in which condition it could be rendered at the lowest possible temperature, when the lard produced would be found to be very different from that generally used.

Mr. Whitley Williams thought the preparation to which Mr. Holmes had referred was very likely to be of great use indeed. He remembered some time ago being at Price's Candle Works when Mr. Hatcher, the chemist there, showed him a quantity of a fat which he believed to be the same thing; it was imported under the name of kokum oil. He said that though freely exposed to the weather it kept almost absolutely without change; it was a dense white fat, something between lard or spermaceti and white wax, and in composition was almost pure stearine, in fact it formed about the best material from which to prepare pure stearic acid.

Mr. Holmes said the material he referred to was not kokum butter, and the seeds from which it came were quite different.

Mr. Willmott said he feared he should be compelled to overlook some of the remarks, whilst many of the criticisms which had been made would be found to be dealt with in portions of the paper which he omitted in reading. He had made no examination chemically of the different hydrocarbons, except such as were involved in the experiments he had narrated; but he thought there was very little difference between them chemically. Vaseline seemed to be prepared by a different process altogether; in fact Messrs. Chesebrough's patent claimed a particular process which did not apply to the other hydrocarbons. That might account for the circumstance that in vaseline alone and not appreciably in the others, the odour complained of became developed. It was claimed that vaseline was not a product of distillation, and thus possibly some of the benzoline oil remained in the preparation, and became developed in the course of time. A good deal had been said about wax, which was a subject well worthy of investigation, but he had not gone beyond the ordinary wax of commerce, which he had always found sufficiently good for the purpose intended. The wax mentioned by Mr. Williams was a special preparation, which he did not think was generally used in pharmacy. He was obliged to Mr. Moss for his experience with regard to vaseline. It was only after a long time in the case of vaseline itself, or after a shorter time when mixed with acetate or carbonate of lead, that the odour became developed; in the latter case he could state that with almost certainty the change would occur within six months. He had used different samples of vaseline, extending over a long time. He had not tested the stage of rancidity chemically as time would not permit; but had simply judged by the physical properties of the ointment. Dr. Symes's suggestion with regard to glycerine was a valuable one, and he would bear it in mind. As far as he knew, white ozokerine, except in its freedom from colour, had no advantage over the yellow kind, and he did not know that Messrs. Field recommended it in preference. He presumed the colour was got rid of by filtration through animal charcoal. Mr. Conroy referred to peroxide of hydrogen producing rancidity; it was simply added to the milder nitrate of mercury ointment to prevent reduction of the mercury. The effect on the lard was no doubt prejudicial. The new substance mentioned by Mr. Holmes was well worth consideration, and in all these cases it was very desirable that sufficient time should be given, and that those ingredients should be mixed with the bases which would test them in the severest manner, otherwise misleading conclusions might be arrived at.

The President said the Conference would no doubt appreciate the discussion which had taken place. There must be room for future research in connection with the material which separated when fats were filtered. He believed the following question would have to be reconsidered: What was the nature of and extent of the action of the material which separated from fats by filtration? He hoped this would be investigated.

(*To be continued.*)

Parliamentary and Law Proceedings.

Poisoning by White Precipitate.

On Tuesday, Mr. F. Price, district coroner, held an inquest on the body of Annie Jane Wood, twenty-five years of age, daughter of Amos Wood, sawyer, residing at Salford. The deceased bought some seidlitz powders on Saturday the 13th inst., at the shop of Mr. G. S. Butcher, chemist, Chapel Street, Salford, and on the following Monday took one of them. She became ill almost immediately, and showed symptoms of poisoning. An emetic was administered, and she was attended by a medical man, but died on Saturday morning.

Mr. B. Cobbett watched the inquiry on behalf of the relatives of the deceased, and Mr. Northgreaves represented Mr. Butcher.

Rachel Wood, mother of the deceased, said that on the 13th inst., her daughter went out to make some purchases, and said that she would call at Mr. Butcher's for some tea on her way back. She also said that she would get some seidlitz powders at the same shop. She had been in the habit of taking seidlitz powders. She brought two powders from Mr. Butcher's shop, and they were put away until Monday. Early on Monday morning witness heard her daughter vomiting. She asked what was the matter, and her daughter said that she had taken one of the seidlitz powders, at the same time showing the witness the cup in which she mixed it. The cup was on the table, and had a sediment in the bottom. As the deceased did not get any better, Dr. Bradley, of Chapel Street, was called in, and that gentleman administered remedies. The deceased, however, grew worse, and died about half-past five o'clock on Sunday morning.—In reply to Mr. Northgreaves, witness said that her daughter was not in the habit of taking powders regularly. She did not see any paper such as seidlitz powders are generally wrapped in anywhere about the room. Deceased told her that the powder did not effervesce.

Dr. Bradley said that on Monday morning, the 15th inst., he attended the deceased and found her suffering apparently from an irritant poison. He sent her as an antidote a powder composed of sulphate of zinc. He visited her again the same morning about eight o'clock. She was lying on the sofa vomiting, and her feet, hands and face were unusually cold. Her pulse was very quick and feeble. She continued in that state for five or six hours, and vomited blood before her death. When he first saw her she told him that she had taken a seidlitz powder from a cup (produced) which was shown to him. He took possession of the cup, and in conjunction with Dr. Clark analysed a portion of the contents. They found a powder called white precipitate. On Monday, with the assistance of Dr. Stocks and Dr. Clark, he made a *post-mortem* examination of the body. From all other internal appearances he was of opinion that death resulted from inflammation of the stomach and intestines produced by some irritant poison. White precipitate was such a poison as would produce such inflammation. He found a small package in the cupboard with the name "G. S. Butcher" on the label. He afterwards went to Mr. Butcher's shop, and after relating to him the circumstances, said: "What did you give the girl?" and showed Mr. Butcher the contents of the cup. Mr. Butcher replied that the deceased purchased at his shop two seidlitz powders in separate packets, and added: "If she has taken any poison it could not possibly have come from here, as these powders are made up in large numbers, and I should say if there was poison in one there was poison in all." Mr. Butcher then, at witness's request, opened the powder which he (Dr. Bradley) brought with him from Wood's house, and put the contents in a measure containing water. It effervesced, the same as an ordinary seidlitz powder. They both drank of the mixture, and he (Dr. Bradley) felt no ill effects. Mr. Butcher showed him a drawer containing at least one hundred of these powders, but he did not remember making any examination of them.—By Mr. Cobbett: The deceased was present when I took the packet out of the cupboard. I carried the cup to Mr. Butcher's, and no one interfered with it afterwards.—In answer to Mr. Northgreaves, witness said the deceased might have taken any irritant poison, besides white precipitate, according to the appearance of the stomach. He was not told by the mother or anybody else that the deceased had had an emetic on the morning of the day she was taken ill. He did not say to the deceased, when she said she had had a seidlitz powder, "But you must have had something else." Deceased was at that time in a very weak state. White precipitate would not effervesce, but it was not a very deadly poison. Deceased was not a very strong girl.—By a Juryman: Witness did not find any traces of seidlitz powder in the contents of the cup he analysed.

Frederick Elsby, assistant to Mr. Butcher (after being cautioned by the Coroner), said he had been with Mr. Butcher for ten weeks. He had had to make up seidlitz powders on more than one occasion. No one else that he knew of had made up any of these powders at Mr. Butcher's shop since he had been there. He made up about nine dozen some days ago, and the ingredients were 4 parts of rochelle salts and one part of carbonate of soda. They were wrapped in blue paper (such as those produced), and a white paper which contained tartaric acid. They were then put away in a drawer in the shop, and he had sold a great many of them since. He could not account for one or any of the powders containing white precipitate. The carbonate of soda was kept in a drawer and the salts in a brown-paper parcel in a cupboard in the shop, and the tartaric acid was also kept in the cupboard. He made up some white precipitate on October 6, but did not use any white precipitate at the time he was making up the powders.—By Mr. Cobbett: Mr. Butcher has an apprentice and he may have wrapped up the powders in blue paper and labelled them without my seeing him.—By Mr. Northgreaves: I never put white precipitate close to the seidlitz powder drawer. On the day I made up the white precipitate I wrapped up and labelled each packet as I made it up.

At this point the inquiry was adjourned until Wednesday. Upon the inquest being resumed,—

Josiah E. Taylor, apprentice to Mr. J. F. Smith, chemist and druggist, Broad Street, Pendleton, said he recollected that one Tuesday, about four weeks ago, Mr. Frederick Elsby, assistant to Mr. Butcher, came to take charge of the shop during Mr. Smith's absence. He came about nine o'clock in the morning, and remained till about ten minutes past nine at night. During the day Elsby measured some of the materials for some seidlitz powders, which he put in blue paper and took away with him when he left. His (witness's) employer sold white precipitate in small penny packets. Mr. Elsby did not use any white precipitate that day, for he did not know where it was kept. Witness did not remember selling any white precipitate that day, and if any got among the material which Mr. Elsby was measuring he could not account for it.—By Mr. Cobbett: I was there all day, and did not see Mr. Elsby make up anything else besides the seidlitz powders. The white precipitate which we make up is placed in white paper and a label is put upon it stating that it is poison.—By Mr. Northgreaves: Mr. Elsby brought the material used for the seidlitz powders in a piece of brown paper.

Mr. G. S. Butcher, chemist and druggist, Chapel Street, Salford, stated that he knew the deceased, who had been a customer at his shop for some years past. She last came on Saturday the 13th inst., and asked for some tea and two seidlitz powders. Witness supplied her, and obtained the seidlitz powders which he gave to her from the drawer in which they were always kept. He heard nothing more of the deceased or of the powders until Monday morning last, when Dr. Bradley called at his shop, having with him a spoon and also a cup, the latter of which, he said, contained the dregs of a seidlitz powder which had been bought there. Witness looked in the cup, and said that was not a deposit likely to come from a seidlitz powder. Dr. Bradley then produced a seidlitz powder which bore his (Mr. Butcher's) label, and stated that he was informed that was also purchased by the deceased at the time she bought the powder which was supposed to have caused her death. Witness put that powder into a tumbler, into which he poured a quantity of water, which caused effervescence. He and Dr. Bradley then tasted the liquid, and Dr. Bradley pronounced it to be all right. Witness afterwards showed the drawer in which the seidlitz powders were kept to Dr. Bradley, and asked him to examine any he liked. He expressed himself satisfied, and did not take any away with him. There was no reason to doubt that the powder in the cup which Dr. Bradley brought with him was white precipitate, but he (Mr. Butcher) could offer no suggestion whatever as to how it came there.—By Mr. Cobbett: I do not remember selling to the deceased or any of her family white precipitate.—By Mr. Northgreaves: As soon as I heard of the death of the deceased, I put the drawer containing the seidlitz powders on one side in order that the powders might all be preserved and analysed if that was thought desirable. Since the last quantity of seidlitz powders was made up I have sold about fifty, and have received no complaint with regard to them.

Dr. Bradley, who was recalled, said there was an absence of pain from the deceased which he could not account for if she had taken any irritant poison.

Mrs. Wood, mother of the deceased, stated that her daughter had not been subjected to any disappointments recently, nor had she been depressed at all.

Alfred Wood and Richard S. Wood, brothers of the deceased, gave corroborative evidence, and stated that they had not been able to find any piece of paper in the house which appeared likely to have contained the seidlitz powder or any kind of poison.

The Coroner, in summing up, said that the case was unprecedented in his experience as coroner and deputy coroner, which extended over twenty years. He had had to inquire into many cases of poisoning, but never one involved in such mystery. It seemed impossible to obtain any definite evidence as to whether the poison really was purchased in mistake for a seidlitz powder.

After the Jury had consulted together in private, the Coroner said that, before the verdict at which they had arrived at was formally recorded, the Jury desired him to express their regret, in which he joined, that the medical gentleman who attended upon the deceased did not communicate with the police in order that the dying declaration of the deceased might be obtained. If that had been done, a very great deal of doubt and difficulty which the Jury had had to contend against would in all probability have been removed.

The verdict at which the Jury had arrived was to this effect:—"That the deceased died on the 21st October from inflammation of her stomach and intestines, caused by having on the 15th inst. swallowed a certain irritant poison called white precipitate; there is, however, no evidence to show how she became possessed of or took the poison."—*Manchester Guardian.*

Prosecution under the Pharmacy Act, Ireland.

At the Armagh Petty Sessions, on Thursday, October 4, a summons was heard in which the Pharmaceutical Society for Ireland charged Wm. Gray and John Gray for that the defendants did within six months last past, to wit, in or about the months of April or May, 1883, and since, sell or keep open shop for retailing, dispensing, or compounding poisons within the meaning of the Act 33 and 34 Vict., c. 26, or medical prescriptions, without having been previously registered as pharmaceutical chemists or chemists and druggist under the Pharmacy (Ireland) Act, 1875, at English Street, Armagh.

A person employed in the establishment of the defendants was called to give evidence respecting the dispensing of certain prescriptions, who displayed considerable perseverance in evading giving a direct answer to the questions put to him. Other evidence was given, however, and eventually the magistrates held that the offence was proved and imposed a fine of £2, with £1 costs.

A second charge against the same defendants of unlawfully assuming a title protected by the Act was then proceeded with and resulted in the imposition of another fine of £2 and £1 costs.

H. E. B. is recommended to examine the precipitate.

NOTES ON TRAUMATICINE.

BY R. MODLEN.

On page 63 of the present volume of the *Pharmaceutical Journal*, appears a notice of the use of medicated gelatine as an application in skin diseases. This is a very good idea, but it is open to two objections which greatly diminish its chance of general use.

The first is, that before use it requires to be melted, a process not always convenient. The second is, that, when applied, it becomes very hard and dry, causing a painful contraction of the skin. True, this may be obviated by painting glycerine over the dry film, but what is wanted is a preparation which will not require so much manipulation. This idea was introduced by Professor Pick, of Prague.

Professor Auspitz, of Vienna, has improved upon it by using a preparation which he calls "Traumaticine," consisting of a solution of 1 part of gutta percha in 10 parts of chloroform. This forms an admirable adhesive, and continues unchanged and adherent to the skin for some days. It produces a very thin, delicate film, causes neither tension nor pain, as gelatine does, is very readily applied, and, as may be inferred from its composition, is quite permanent, whereas the gelatine becomes mouldy. Here, at the Radcliffe Infirmary, Oxford, it has been used by Mr. H. P. Symonds with great success in psoriasis. In making it, I use the gutta percha tissue, which answers the purpose quite as well as the purified gutta percha. In appearance it is a thick fluid, of a purplish colour. In preparing it with any medicament, *e.g.*, acidum chrysophanicum, I dissolve the acid, etc., in the chloroform, before adding the gutta percha.

I submit these notes in the hope that they may be useful to any brother pharmacist who may have "traumaticine" ordered.

THE INDICATION OF ALKALINITY IN THE ESTIMATION OF HYDROCYANIC ACID.

BY PETER MACEWAN.

In the estimation of hydrocyanic acid by Liebig's process there is sometimes difficulty in ascertaining that the acid has become completely saturated with the alkali used, owing to the sodium cyanide formed being alkaline to litmus, even in presence of free hydrocyanic acid. The indication thus given is misleading, and is calculated to impair the results of the titration. In Dr. Senier's method for overcoming the difficulty soda solution is added to a strong alkaline reaction, indicated by litmus tincture, and should the solution become acid during titration more soda is added, so that the whole may be alkaline at the final reaction. This plan is generally adopted and it gives good results, but it does not obviate loss of hydrocyanic acid by exposure.

By substituting phenolphthalein for litmus alkalinity is indicated with certainty, so that the titration may be carried through without interruption.

This new indicator is not affected by sodium cyanide, and if a single drop of its solution be added to the hydrocyanic acid previous to the addition of soda solution, no change occurs until the acid is wholly converted into sodium cyanide and the solution has become slightly alkaline, at which point a pale crimson colour appears and no more soda is required. Titration may then be proceeded with.

I have no doubt that others may have used phenolphthalein for this purpose, but this suggestion may be useful to those who have not. The solution which I use contains 4 grains in an ounce of proof spirit. It may be proper to add that the indicator is of no use in presence of ammonia.

THE NEW PHARMACOPŒIAS FOR THE UNITED STATES AND GERMANY.

(*Continued from p.* 302.)

Quinidinæ Sulphas, U.S.P.—"The neutral sulphate of an alkaloid prepared from different species of *Cinchona*, chiefly *Cinchona Pitayensis*." In white silky crystals, permanent in the air, odourless, having a very bitter taste and neutral or faintly alkaline reaction. Soluble in 100 parts of water at 15° C. or 8 parts of alcohol; in 7 parts of boiling water and very soluble in boiling alcohol; in 20 parts of chloroform, but almost insoluble in ether. It parts with its water of crystallization (4·3 per cent., equal to two molecules at 120° C.). An aqueous solution, acidulated with sulphuric acid is fluorescent, and when treated with fresh chlorine water and then with slight excess of solution of ammonia the salt gives an emerald green colour like quinine.

Quinine, U.S.P. (new).—The official quinine is the form crystallizing with three molecules of water, occurring as "a white, flaky, amorphous or minutely crystalline powder." It is described as soluble in 1600 parts of water or 6 of alcohol at 15° C., in 700 parts of boiling water, in 2 parts of boiling alcohol, about 25 parts of ether, 5 of chloroform, 200 of glycerine, and also in benzin, benzol, water of ammonia or dilute acids, which it neutralizes. It melts at 57° C., loses 2 molecules of water in the water-bath, and the remainder at 125° C. The vivid blue fluorescence with dilute sulphuric acid and the thalleioquin reaction are given as characters of the alkaloid and of its salts, as are the requirements that they shall not be coloured or rendered more than a pale yellow by strong sulphuric acid (absence of foreign organic matters) or reddened by nitric acid (difference from morphine). But the principal test is a modification of Kerner's test, which is also modified to adapt it to the official salts of quinine. A gram of quinine is mixed with 0·5 gram of ammonium sulphate and 5 c.c. of distilled water, the mixture thoroughly dried on a water-bath, the residue (which should be neutral to test paper) agitated with 10 c.c. of distilled water, the mixture macerated for half an hour at 13° C., and filtered. Upon adding to 5 c.c. of the filtrate in a test-tube, 7 c.c. of solution of ammonia, sp. gr. 0·960, and gently turning the tube until the two are intermixed, a clear liquid should be obtained, which it is stated would indicate the absence of more than 1 per cent. of cinchonidine and quinidine, and of more than traces of cinchonine. The proportions of the saturated solution and of ammonia are those indicated by Kerner for pure sulphate of quinine, but in this case, as an excess of ammonium sulphate is ordered, which is very soluble in water, some of this salt would be present also in the saturated solution to which the ammonia is added.

Quininæ Bisulphas, U.S.P. (new); *Chininum bisulfuricum*, P.G.—This soluble salt of quinine is described in the U.S.P. as in colourless clear orthorhombic crystals or small needles, efflorescing and becoming opaque on exposure to the air, having a very bitter taste and a strongly acid reaction, and represented by the formula, $C_{20}H_{24}N_2O_2H_2SO_4 \cdot 7\,H_2O$. Soluble in about 10 parts of water, with vivid blue fluorescence, and in 32 parts of alcohol at 15° C., and very soluble in boiling water or alcohol. The description in the P.G. is practically the same, and the statement that the residue from 100 parts dried at 100° C. should weigh 77 parts, points to the same amount of water of crystallization. In both works a modification of Kerner's process is used as a test for the absence of other alkaloids, the bisulphate being first converted into neutral sulphate by the addition of ammonia, the only difference being that in the P.G. a mixture of 2 grams of bisulphate and one of solution of ammonia is evaporatad to dryness and the residue examined, whilst in the U.S.P. a solution of bisulphate is carefully neutralized with ammonia, and then made up to the proper quantity with water.

Quininæ Hydrobromas ($C_{20}H_{24}N_2O_2HBr \cdot 2H_2O$), U.S.P. (new).—Coloured lustrous needles, permanent in ordinary air, but readily efflorescing at a gentle heat, odourless, having a very bitter taste and neutral or slightly alkaline reaction. Soluble in about 16 parts of water or 3 of alcohol at 15° C., in 1 part of boiling water or alcohol, in 16 parts of ether, 12 parts of chloroform, and moderately in glycerine. Besides the tests that are common to the other quinine salts, an aqueous solution of the hydrobromate should not be rendered turbid by test solution of barium chloride, showing the limit of sulphate. In order to apply Kerner's test, 1·5 grams of this salt is dissolved in 15 c.c. of hot distilled water, the solution stirred with 0·6 gram of crystallized sodium sulphate in powder, the mixture maintained at 15° C. for half an hour, and then drained through a filter only large enough to contain it until the 5 c.c. required is obtained. Dried on a water-bath it should not lose more than 8·2 per cent. (2 molecules) of water.

Quininæ Hydrochloras, U.S.P. (new); *Chininum hydrochloricum*, P.G.—According to the U.S.P., occurring in white lustrous needles, forming tufts, permanent in ordinary air, but readily efflorescing at a gentle heat, odourless, having a very bitter taste and a neutral or faintly alkaline reaction. Soluble in 34 parts of water at 15° C., or 3 parts of alcohol, in 1 part of boiling water, and very soluble in boiling alcohol; when rendered anhydrous (by which it should not lose more than 9 per cent. in weight) it is soluble in 1 part of chloroform. An aqueous solution does not show any blue fluorescence and should not be rendered turbid by test solution of barium chloride. In applying Kerner's test in the U.S.P. 1·5 gram is ordered to be dissolved in 15 c.c. of hot distilled water, the solution stirred with 0·75 gram of crystallized sulphate of sodium in powder, the mixture maintained at 15° C. for half an hour, and then drained through a filter only large enough to contain it until 5 c.c. of filtrate is obtained. The P.G. orders 2 grams of the salt, with 1 gram of sodium sulphate and 20 grams of water, to be evaporated to dryness, the residuum boiled with 12 grams of spirit, filtered and evaporated, and the resulting "chininum sulfuricum" examined. According to Schlickum (*Ph. Zeit.*) complete decomposition does not take place under the P.G. conditions, and the salt removed by the alcohol from the dried mixture is principally unaltered hydrochlorate. It will be remembered that the use of hydrochlorate of quinine instead of sulphate in the preparation of tincture of quinine, on account of its greater solubility, has been several times recommended in this Journal (see *Pharm. Journ.*, [3], xii., 1068).

Quininæ Sulphas, U.S.P.; *Chininum sulfuricum*, P.G.—The U.S.P. formula for this salt represents it with seven molecules of water of crystallization, but one of the tests allows it to lose when heated to 100° C. for three hours as much as 16·8 per cent. of water, or equal to eight molecules. The P.G. requires that after drying 100 parts at 100° C. the residue should weigh at least 85. Both Pharmacopœias give Kerner's test amongst others, and the P.G. also gives Hesse's chloroform-alcohol test, according to which 1 gram of quinine sulphate when heated for a short time at a temperature of 40° to 50° in 700 c.c. of a mixture of two volumes of chloroform and one of absolute alcohol is completely dissolved and the solution remains quite clear when cool.

Quininæ Valerianas, U.S.P.—White or nearly white pearly lustrous, triclinic crystals, permanent in the air, and having a slight odour of valerianic acid, a bitter taste and a neutral reaction. Soluble in 100 parts of water at 15° C., and 5 of alcohol; in 40 of boiling water and 1 of boiling alcohol and slightly soluble in ether. Melts at about 90° C. This salt was in P.G. 1870, but has been omitted from the new edition.

Salicinum, U.S.P. (new).—"A neutral principle prepared from the bark of *Salix Helix*, L., and of other species of *Salix*." In recognition of the place which this glucoside has now attained amongst therapeutic agents, especially in the treatment of rheumatic fever, it has been included in the U.S.P., though not in the more conservative P.G. It is described as occurring in colourless or white silky crystals, permanent in the air, odourless, having a very bitter taste and a neutral reaction. Its solubility in water at 15° C. is given as 1 in 28, which corresponds with the results arrived at independently by Mr. Parker and Mr. Dott (*Pharm. Journ.* [3], xii., 378 and 615). Soluble in 30 parts of alcohol at the same temperature; in 0·7 part of boiling water; and in 2 parts of boiling alcohol; insoluble in ether or chloroform. It melts to a colourless liquid at about 198° C., and on ignition emits vapour having the odour of salicylous acid and is finally wholly dissipated. One part of salicin shaken with 20 parts of water and 5 parts of solution of potash gives a clear colourless solution. Cold concentrated sulphuric acid dissolves it with a red colour, and this solution after the addition of water becomes colourless and deposits a dark red powder insoluble in water or alcohol. Salicin is distinguished from alkaloids in not being precipitated from an aqueous solution by tannic or picric acid, or by iodide of mercury and potassium.

Santoninum, U.S.P.; P.G.—The reports several times repeated during recent years of accidents having happened through the contamination of santonin with strychnine appear to have led to the introduction into both Pharmacopœias of a test to guard against the presence of that alkaloid. In the U.S.P. the supernatant liquid after precipitating the santonin from a solution in sulphuric acid by the addition of water, and in the P.G. the clear liquid obtained by boiling santonin in 100 parts of water and 5 parts of sulphuric acid, slowly cooling and filtering, should not be altered on the addition of solution of bichromate of potassium, the yellow chromate of strychnine being formed if the alkaloid be present.

(*To be continued.*)

The Pharmaceutical Journal.

SATURDAY, NOVEMBER 3, 1883.

Communications for the Editorial department of the Journal, books for review, etc., should be addressed to the EDITOR, *17, Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary, 17, Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

A GERMAN EDICT AS TO THE KEEPING AND SALE OF POISONOUS SUBSTANCES.

PERHAPS the greatest of the difficulties in connection with the subject of the regulation of the sale of poisons in this country is experienced in attempting to deal with two widely differing moods of the public mind, the one manifest, when, under the influence of temporary panic provoked by some untoward occurrence, a cry is raised for extreme restrictions concerning the keeping and sale of every substance that can be regarded as poisonous, and the other when the inconvenience resulting from restraint in manufacturing and trading operations is recognized as a sufficient reason for allowing dealings in indefinite quantities of virulent poisons to remain free from any control. Thus, when in consequence of repeated and influential representations the Council of the Pharmaceutical Society sought to exercise its statutory powers by including certain widely used poisons in the second part of the schedule its experience was hardly a happy one, and certainly the portion of the draft Bill to amend the Pharmacy Acts that has met with the largest amount of opposition is that which proposes to meet the difficulty by instituting a class of "poisonous" substances that might be sold by unregistered persons, but only under certain restrictions as to labelling. It is quite possible that in this country conflicting interests may long preclude a settlement of this question; but in Germany, where—we do not say whether fortunately or unfortunately—the form of government is more paternal, the public and the pharmaceutical community are liable to have the question settled for it in a somewhat more summary manner. This indeed has recently occurred in the Prussian district of Königsberg, where a police regulation has been issued respecting the sale and keeping of poisons and poisonous substances, which, as will be seen, is not wanting in stringency.

In the first place, concerning what are to be deemed poisons and who are to be allowed to sell them, it may be stated that as a basis of the police regulation referred to, a large number of poisonous substances used for other than medicinal purposes are grouped in two classes: the first, entitled "direct poisons," which are to be kept in poison chambers, as afterwards described, and the second, called "indirect poisons," which are to be kept separately from other substances. Class I. includes (*a*) all arsenical substances, such as arsenious acid, vermin killers, fly papers and similar preparations containing arsenic, arsenical pigments and colours, aniline colours containing arsenic, and all preparations and substances which contain arsenious or arsenic acid, or a compound of either; (*b*) all mercurical preparations; (*c*) all cyanides and compounds containing hydrocyanic acid, such as essential oil of bitter almonds, and (*d*) phosphorus and its preparations. In Class II. are placed (*a*) all poisonous and powerfully acting drugs and chemicals, including all those enumerated in Table C. in the German Pharmacopœia, so far as the sale of these is allowed, and especially carbolic, chromic, hydrochloric, nitric, nitrous, nitro-hydrochloric and sulphuric acids, oxalic acid and oxalates, caustic potash and soda and caustic leys, butter of antimony, lunar caustic and other silver salts, soluble salts of barium, cadmium and copper, salts of tin, sugar of lead, iodine and iodide of sodium, nitrobenzol, coculus indicus, mezereon seeds, and poppy heads; and (*b*) poisonous pigments, especially those containing lead, chromium, copper or zinc, under whatever name they may pass. The police regulation prohibits absolutely the keeping or sale of any of the foregoing articles, or poisons or poisonous substances of any kind, by any person who is not a pharmacist, unless he holds a special licence, such licences being obtainable in towns from the police authorities and in country districts from the provincial courts. A pharmacist does not require a licence, and in respect to the foregoing poisons and those contained in Tables B. and C. of the German Pharmacopœia he remains in exactly the same position as before the issue of the order. Subject to the possession of a licence, however, and with the exception of certain substances which were the subject of a previous order that limited dealing in them by wholesale to merchants and by retail to pharmacists, the sale of poisons not intended for medicinal use may be carried on by other traders than pharmacists, provided that certain stringent conditions as to keeping and delivering them are complied with.

All the poisons and poisonous pigments included in Class I., with the exception of phosphorus and its preparations, are to be stored by dealers in special poison chambers, used only for this purpose and separated from the ordinary business apartments. These chambers are to be kept always locked except during the time in which they are being used; moreover they are to be accessible only to the principals of the establishment and adult assistants, and are to be well lighted by daylight and kept clean and tidy. The poisons are to be placed in strong, durable, well-closed vessels, distinctly labelled with oil colours in white letters upon a black ground, and so arranged that the poisons in the different categories do not stand beside or under one another, but the arsenical, the mercurial, and the cyanogen groups and the other "direct poisons" are each placed in a separately locked compartment bearing the corresponding label. Each of these compartments must be provided with its own set of the necessary scales, mortars, scoops, etc. Phosphorus is to be preserved under water in a glass vessel surrounded by sand, enclosed in a metal case, and this, together with preparations of phosphorus, is to be placed in a fire-proof cellar that can be locked. As to poisonous substances in Class II., the boxes or other containing vessels used for them are both in the store and the sale-room to be kept entirely separate from all other goods. In the store, if not kept in special chests they are at least to be separated from other wares by a lattice-work partition and especially from articles of food and medicine. In the sale-room these poisons are never to be placed near articles of food. All boxes or vessels containing poisons of this class are to be labelled in red letters upon a white ground, and there is to be a special set of scales, etc., to be labelled "poison," and used for nothing else. After the poisons in either class have passed from the dealers to persons requiring them for technical purposes they are still to be stored under lock and key, separately from all other articles, and in vessels that are each to be labelled with the name of the substance, the word "poison," and three distinct crosses on the vessel and on its lid.

With respect to the act of selling the provisions are equally specific. No poison in Class I. is to be sold in any quantity except upon a "poison order," which must be signed and sealed by the buyer, and state the date of the purchase, the name of the buyer, the name of the messenger, the kind of poison wanted and the quantity, and the purpose for which it is required. The seller has to number the poison orders consecutively and preserve them so as to be able to produce them if called upon by the authorities and has also to make a corresponding entry of the particulars in a "poison book." These "direct poisons" are, moreover, only to be sold for technical purposes to artists or to persons carrying on a business in which they are required or who are engaged in the destruction of vermin, and only then when the buyer is personally known to the seller or is able to prove his identity by a certificate specially issued for the purpose by the police authorities of his district. White arsenic is only to be supplied for the destruction of vermin after being coloured, and the same is the case with poisoned wheat, whilst fly-papers are to be stamped with the word "poison" and three conspicuous crosses. The packing and labelling of these substances is to be completed in the "poison chamber," and particular instructions are given as to the way in which these operations are to be carried out. Some of the poisonous substances in Class II. also—the strong mineral acids and caustic ley—are only to be supplied upon a poison order, whilst the others may be delivered without one to a person known to the seller; but all are to be packed and labelled according to instructions. Rat catchers and similar useful persons who obtain poisons for the purpose of their business are prohibited from supplying them, and are required to lay the poisonous bait themselves, and in such a manner and so distinguished in colour or smell as not to be likely to be mistaken by human beings or domestic animals. Finally, the sale and use of arsenical pigments for the colouring of papers, tapestries, tarlatans, cloths, etc., and the dealing in and keeping of all fabrics coloured by means of arsenical pigments, are forbidden, unless special permission has been granted.

It would therefore appear that if the people of Königsberg are not in future exempt from cases of accidental and criminal poisoning it will not be because they are not legislated for. Indeed, to English eyes the whole scheme will probably appear to be one of those specimens of over-regulation which defeat the objects they are intended to serve. But as in the administration of the order the members of the district medical board are associated with the police authorities, it may be assumed that they, at least, have been consulted upon the subject. At any rate whilst the order remains in force offences against its provisions are to be punishable by a fine of thirty shillings or a proportionate imprisonment, except in cases where a higher penalty had been already provided for under existing laws.

At the Evening Meeting of the Pharmaceutical Society on Wednesday next, two papers will be read, one on "The Preparation of Lard for Use in Pharmacy," by Professor Redwood, and the other on "The Classification and Properties of Red Resins known under the name of Dragon's Blood," by Messrs. Dobbie and Henderson. In connection with the latter paper Professor Bailey Balfour has promised to exhibit specimens of dragon's blood resin and the tree brought by him from Socotra, and to make some remarks upon the plant and its affinities. The chair will be taken at half-past eight, but in accordance with the arrangement recently announced the Lecture Theatre will be opened at half-past seven in order to give visitors an opportunity before the meeting begins of examining the donations to the Museum received during the past six months and various other articles of interest that will be exhibited.

* * *

On Monday evening next, at 9 p.m., a meeting is to be held at 17, Bloomsbury Square, for the purpose of making preliminary arrangements for the usual Chemists' Ball, at which all gentlemen interested in the subject are invited to attend.

* * *

Referring to the suggestion that a recent supposed case of poisoning was possibly due to the substitution of a packet containing white precipitate for one containing a portion of a seidlitz powder, Mr. F. W. Bates, of Manchester, suggests that such accidents might be prevented to some extent by always wrapping poisonous powders in paper of a peculiar pattern; for instance, white paper with distinct red bars printed across it. The suggestion seems worthy of consideration, since the use of a special paper for poisonous solids would not be subject to one important drawback attending the use of special bottles for poisonous liquids, that they are sometimes afterwards used for harmless liquids and so lead to confusion.

* * *

The report of the Local Government Board shows that the provisions in the Sale of Food and Drugs Act for the analysis of samples purchased by private persons are not much used. Out of 19,439 samples analysed during 1882, there were only 429 that were not obtained by the local officials. But it is significant that 242 of these were submitted for examination in the three boroughs of Salford, Bristol and Brighton, in the two former of which the fee to be paid by private individuals has been fixed as low as 2*s.* 6*d.* for each analysis.

* * *

A report has recently been issued as to the proceedings at the Municipal Laboratory which was established about two years since in Paris, for the examination of articles of food and drink suspected to be adulterated. In Paris there is a single official laboratory for the whole city, with a staff of six analysts and assistants, kept up at an expenditure annually of a little over £3000. Attached to this staff there are thirty-two inspectors, whose duty it is to visit the markets and shops and procure samples for analysis. The samples are reported upon as "good," "tolerable," "bad, but not injurious," or "bad and injurious," about half the number examined hitherto having fallen under the last category. Any member of the public is entitled, on taking a sample to the laboratory and giving particulars as to its origin, to be furnished gratuitously with the results of a qualitative analysis specifying approximately its character; but for a quantitative analysis a sum ranging from five to twenty francs has to be paid. If, however, a sample brought in this way is found to be adulterated, an inspector is at once sent to the alleged place of purchase to obtain another sample, upon the result of the analysis of which, if adulteration is detected, legal proceedings are based. There appears to be no arrangement like that by which, in this country, the seller is enabled to check the public analyst's results by an independent analysis.

* * *

A correspondent writes:—"It may interest some of your readers to hear, as illustrating the mildness of the season, that a chestnut tree, a few doors east of the Vestry Hall, in the Peckham Road, is now in blossom. I cannot state precisely the number of blooms, but there must certainly be between eighty and a hundred; they are of course stunted in growth, but surrounded as they are with a whorl of leaves, they give the otherwise naked tree a very singular appearance."

* * *

In accordance with a custom that obtains with the American Pharmaceutical Association the first proceeding at the recent meeting was to listen to an address of welcome from a local official, who on this occasion was one of the commissioners of the District of Columbia. This gentleman expressed on behalf of his colleagues admiration for the efforts of the Association to elevate the standard of the pharmaceutical profession, and told the assembled pharmacists that "the labours of its members, their analysis and research, co-operating with and aided by kindred societies in other lands, are perfecting step by step the grand work of evolving from the myth of credulity and the terrors of superstition a science that cares for and relieves suffering humanity with a skill and intelligence that few outside the ranks of its devotees have any conception of." They were also assured that "this bringing together of the men from Maine and the men from Texas, of the dwellers on the Atlantic coast and those from the far off shore where rolls the Oregon, gathering to their ranks members of commingling localities as they verge towards the nation's centre, should have as salutary an effect upon the body politic as their deliberations and intercourse shall promote the welfare and health of the body physical." There was also a reception given by President Arthur at the White House on the afternoon of the third day of the meeting. After this our United States *confrères* can hardly complain that their countrymen are wanting in appreciation of their virtues—at any rate as far as this can be manifested in words.

* * *

We are glad to observe, too, that there was evidence of satisfaction amongst the pharmacists themselves at the position they have attained. Speaking of the earlier days of the Association, Mr. President Heinitsh said, "The sentinels of the dawn are answered by the ranks of the day. The cry of the first decade was, 'We may be!'; the decade now opening gives reply, 'We are!'" Referring to the production of three successive pharmacopœias by conventions sitting in Washington, and the fact that three-fifths of the members of the present Pharmacopœia Convention are members of the American Pharmaceutical Association, Mr. Heinitsh said that results have shown each later edition to be far in advance of its predecessors, and the last revision to be "a promontory of solid worth, a beacon light and guide."

* * *

By the way, this praise notwithstanding, the members of the Pharmacopœia Convention themselves do not appear inclined to "rest and be thankful." The presence of many of the members in Washington was taken advantage of for a meeting, at which it was resolved that correction should be made of all the recognized errors, and that some desiderata, among them some tables and some approved and commonly used remedies and preparations, but no other new remedy, should be included in an "Appendix," to be issued as soon as possible.

* * *

The managers of the Berlin Chemical Manufacturing Company state in a circular that in a competing "tannic acid they have found 10 to 15 per cent. of substance insoluble in alcohol, besides regularly 6 to 8 per cent., and in one instance 25 per cent. of potato starch. The 10 to 15 per cent. of insoluble substance might be referred to the use of too weak an alcohol in extracting the galls, but the presence of the starch needs no commentary.

* * *

We are glad to learn that Mr. D. Morris has a work in the press on the colony of British Honduras, with particular reference to its indigenous plants and economic productions, which it is understood will give valuable information concerning the flora and resources of that colony, and we look forward with interest to what he may have to reveal concerning its medicinal products.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The first general meeting of the thirty-fifth session of the above Association was held at the Royal Institution on Thursday, October 11; the President, Mr. E. Davies, F.C.S., F.I.C., in the chair.

The minutes of the last meeting were read and confirmed, and the following donations announced:—The current numbers of the *Pharmaceutical Journal*; the 'Nineteenth Annual Report of the Alumni Association of Philadelphia;' 'Proceedings of the Second Annual Meeting of the Massachusetts State Pharmaceutical Association;' 'The Organic Constituents of Plants and Vegetable Substances, and their Chemical Analysis,' by G. C. Wittstein, from the Government of Victoria; 'A Treatise on Olive Culture,' by Ellwood Cooper, from the same; the Annual Report of the Liverpool Science Students' Association.

Dr. Symes mentioned that Mr. E. M. Holmes, Curator of the Pharmaceutical Society's Museum, had recently, when in Liverpool, given some valuable information and advice respecting the Association's museum.

The President then asked the Honorary Secretary to give the names of the officers elected at the last Council meeting. They were as follows:—Vice-President, A. H. Mason (re-appointed); Treasurer, R. M. Sumner (re-appointed); Honorary Secretary, Albert H. Samuel, *vice* A. C. Abraham (resigned); Librarian, E. Dowling.

The President then read his

Introductory Address.

After a lapse of ten years, I have again been called to preside over your meetings. When one's attention is thus called to the swift course of time, it seems only natural to survey the period which has gone and see what it has carried away, and what still remains with us. So far as the members of the Society are concerned, at least with regard to those who take a prominent part in its proceedings, there has not been much change; of the members of Council then existing only one has been removed by death, and although advancing years may compel some of our older friends to diminish their active exertions in aid of the objects of our Association, their hearts are still with us, and the sons are taking the place of the fathers. During these ten years we have not been asleep; there have been lively discussions, alterations of laws, efforts to enlarge the bounds and increase the usefulness of the society, and I trust that whatever may be needed to keep the Association in vigorous and healthy life will not be wanting. I think no one will find fault with one change, with which my own name is to some extent associated, namely, the election of President by the whole body of members instead of by the Council, and the additional time for the preparation of an address afforded by the election taking place before the recess; and personally, I find it a great advantage not to have to lay before you a hurriedly compiled address. If from our little portion of the great field of knowledge we look abroad, we see that the progress has neither been slow nor small. If we first take into consideration advances in practical chemistry, there can be no doubt that the artificial production of indigotine, in a manner to be commercially applicable, must take the first place, whether we look upon it as a triumph of chemical science, the importance of it commercially, or the greater range of indigo tints which may be obtained; in all these respects it is a discovery which stands prominently forward in the history of chemistry. Although artificial indigotine cannot yet be produced at a price which will drive natural indigo out of the field, yet looking at the allied case of alizarine, one cannot doubt that as the initial difficulties have been surmounted, improved and cheaper means of carrying out the process will be discovered, until we need not look beyond our own country to supply us with all the indigo we require. It is true that it is to our German neighbours we owe this new advance, as we do in so many other cases, but if a greater impetus be given to the encouragement of scientific research by the revelation of the materially valuable results which flow from it, we may indirectly be spurred on until our own land be second to none in that science in which she was at one time pre-eminent.

Salicylic acid, as an article of commerce made artificially, is also a product of the last decade. A scientific curiosity ten years ago, it is now a recognized remedy of great value, and has applications as a preservative and antiseptic which are continually increasing. In last year's examinations in technology, of the City and Guilds of London Institute, it is stated to improve yeast, and the student is asked how much he would use for a quarter of malt. Truly our beer is becoming a chemical compound indeed.

Paraconine is another wonderful result of the endeavours to artificially reproduce organic bodies. Though not identical with the conine of the hemlock it is an isomeride of it, and if its physical properties exhibit some slight differences its physiological effects seem to be almost identical.

Turning to inorganic chemistry, the decade has been marked by the introduction of the ammonia soda process into England.

In a paper read before the Society of Chemical Industry by Mr. Walter Weldon, the enormous influence of this new industry on the manufacture of soda ash by the Leblanc process is powerfully set forth. Already the chemical industries dependent on the Leblanc process are carried on for the smallest profits, and but for the fact that hitherto no practical means of utilizing the chlorine in the salt has been found out in connection with the ammonia process, the days of Leblanc's process would seem to be numbered. As a instance of the manner in which progress in one direction entails progress in others, I think that there are few more striking than the response to the demand for ammonia in Solvay's process. With prodigal hand have we been throwing away ammonia and tar by the ton, whilst we carefully saved it by the hundredweight. Gas manufacture was practically the only source of these products, ever increasing in value; the ammonia for fertilizing our land, the tar as a source of colouring matters, disinfectants, explosives, etc. Yet all the while, in the manufacture of coke, far greater quantities were destroyed or sent almost uselessly into the atmosphere. It was supposed that the manufacture of good coke rendered the loss of these an inevitable necessity, but "inevitable" like "impossible" should be erased from the chemist's dictionary. Now more than one process has been perfected, whereby, without injuring the coke, these products may be collected profitably. Now let us trace the probable results in the future. If other valuable products than coke can be got from coal, coke will become cheaper, and will largely affect the iron manufacture, besides providing a smokeless fuel for other purposes. We may hope that the smoke nuisance may thus be moderated, and waste of fuel, a matter of national importance, diminished. Again, the introduction of electric lighting, in the opinion of many, threatens the use of gas with extinction. Without necessarily holding this view, for gas, as a heating agent and motive power, has an undeveloped future before it; if we do not hold gas shares we may look philosophically upon the banishment of gas retorts and gas holders from our midst. Ammonia and tar will still be found, and will probably be cheaper than ever. If ammonia salts can be obtained at a lower rate, the unfortunate British farmer may still be able, by artificial fertilizers, to compete with foreign competition, and we are brought to the region of political economy, into which our Association luckily has no business to stray.

I have no intention to wander farther in the field of imagination; possibly, starting with Solvay's process, we might land in Utopia; but enough has been said to show how inextricably linked is the chain of research, and how the chemist, in his laboratory, may, more fortunate than Archimedes, find a fulcrum for a lever to move the world onward.

Not only in the practical applications of chemical science has progress been made. In the department of pure chemical science men whose aim is only to extend the knowledge of the laws of nature have been engaged in their noble work. It is in these studies, to the outsider so utterly useless, that principles are evolved whose far reaching results none can foretell. The true character of the elementary bodies, whether they are indeed truly distinct forms of matter, or whether there is an underlying unity, has long perplexed the inquirer, and still there is no decisive reply. No element has yet been decomposed into simpler forms, yet we seem on the verge of some such discovery. When a whisper was heard that chlorine had been decomposed, no chemist felt surprised that it should be so, and although the anticipation proved erroneous, V. Meyer's researches have advanced us a long stride on the way. The molecules of bromine and iodine, and probably chlorine have been resolved into their constituent atoms by heat alone, and we are thus set face to face with matter in an atomic form, instead of the more complex molecule. Attacking the same question from a different side, Mr. Norman Lockyer has, in the varying spectra of elements exposed to successively increasing degrees of heat, seen reason to believe that evidence was obtained of successive decompositions. Though his deductions from his observations have not been accepted as proved, a new field for research has been opened, and we may hope that it will yield fruit in the not far distant future. Now that the production of electricity by mechanical means has placed this enormously powerful agent at the service of the physicist in a more readily available form, we may hope that it will be made use of to a greater extent than hitherto, and this should give a means of decomposition greater than mere heat, or any known chemical reactions.

In support of direct attacks upon the elements, the theoretical arguments as to their possibly compound nature have been strengthened by the remarkable observations of M. Mendeleff. Extending the investigations of former workers in this direction, he has tabulated the elements in the order of their atomic weights in such a manner as to show that they follow one another at small distances, and where the gap is too large he has boldly predicted the existence of missing members. These predictions have met with one striking verification. The element gallium comes in the place of one of the gaps, and has the properties which an element in that place should have. Until these researches were made the discovery of new elements was a matter of chance, the prediction of their properties would have been considered ridiculous, but now M. Mendeleff has pointed out the directions in which research should go and has greatly facilitated the detection of new elements. By his classification of the elements, those whose properties present common characters, as chlorine, bromine and iodine, fall into regular order. and the suggestion is almost irresistible, that there is an underlying unity, notwithstanding the surface differences, linking all the elementary forms of matter. Whether we shall ever discover the nature of the unity, or the cause of the differences, is of course purely speculative; still more so, whether we shall ever be able to realize the dream of the alchemists and transmute one form of matter into another, but we have not now to work in the total darkness of the old chemists, but are aided by stray gleams of light.

The nature of chemical force has also received a large amount of attention. Having recently treated on this subject before another society in this city, I shall now only refer to some experiments by Dr. Spring. The close connection of chemical force with that known as cohesion has long been suspected. Some compounds are so loosely held together that slight mechanical agitation is sufficient to unlock their bonds, as iodide of nitrogen, which is resolved into its component elements by the mere touch of a feather. Faraday, in his lectures on the forces of nature, heads the chapters on chemical force with "Chemical Force—Cohesion," showing that he considered that the force which holds the elements in a compound in a state of union, was at least analogous to that by which the atoms of a single element are joined so as to form a coherent mass. M. Spring began by showing that lead filings powerfully compressed united to form a solid mass similar to that obtained by fusion. This was also the case with bismuth, tin, copper, sulphur, etc. He then mixed copper filings and sulphur, and at a pressure of 500 atmospheres obtained the compound copper sulphide. Zinc and sulphur gave sulphide of zinc, presenting the appearance of native blende. Iron and sulphur gave sulphide of iron, which evolved sulphuretted hydrogen with acid. On heating the sulphide of iron thus made, it fused without any evolution of light and heat such as would be presented by a mixture of sulphur and iron. The artificially made sulphide of copper showed the same absence of luminous phenomenon on heating. Subsequently, compounds of arsenic with metals were produced at a pressure of 6500 atmospheres, possessing crystalline structure and forming definite chemical compounds. Most striking of all, a mixture of iodide of potassium and chloride of mercury subjected to pressure brought about soluble decomposition with production of iodide of mercury and chloride of potassium. It is true that we are ignorant of the nature of the force which holds together the particles of an element in a coherent mass, but it is a distinct gain to know that chemical force is not a force *sui generis*, but is probably identical with one with which we are familiar, and so an approach to the greater simplicity of our conception of force is gained. It is to be hoped that these important experiments will be continued and subjected to a thorough investigation, as, in my opinion, they are amongst the most important of modern times.

So far I have endeavoured to point out a few recent advances in the directions of applied and pure chemistry, and now I wish to consider the bearing of this part of my address on the object and state of our Association.

In the report recently laid before you it was stated that a society of a more purely scientific character had robbed us of some of our members. This is the case with reference to those who have a more direct interest in the applications of chemistry to some of our great manufacturing industries. But surely in these days in which science interpenetrates all branches of human industry, those, whose name of chemist is legally indefeasible, although the division of labour has narrowed the materials on which their attention is mainly concentrated to those which are used for medicinal purposes, should not be insensible to the importance of a knowledge of the chemical principles involved in the manufacture and compounding of those important substances with which they deal. If, thirty-five years ago, when no legislative authority compelled the pharmacist to have a knowledge of chemistry and allied sciences, such as he must now possess in order to take the title of chemist and druggist, men were found in this city who were impelled by the love of knowledge to found this Association, now the need must be greater for association with one another. The objects set out then were "the advancement of chemical and pharmaceutical science." Not content with merely making themselves acquainted with what other men had done, the founders of this Association laid down as their clearly defined aim, the adding of original matter to the sum of human knowledge. No one can look over the reports of the Association without seeing plentiful evidence that those objects have been kept in view, and carried out in an effectual manner. These memories of past labours should incite us to rivalry with our predecessors, and make us resolve that in our hands the Association shall suffer no deterioration.

The report goes on to say that the Council have had under consideration the admission of what are known as "trade questions" for discussion at our ordinary meetings. Here I may be allowed to make some personal allusions, as some years ago, when some members, myself among them, had a vision of a "Liverpool Chemical Society," to be developed by a more exclusive attention to purely scientific chemistry, not excluding scientific pharmacy, I did then take a very distinct position in opposition to the introduction of trade questions. Knowing what I did then you have elected me as your President now, and as I wish that there shall be no doubt as to my views, I trust you will excuse me if I fairly lay them before you. The dream of past years has faded; I recognize that the Liverpool Chemists' Association must now look to pharmacists, wholesale and retail, for its principal support, and that, in fact, it has reverted to the exact conditions which existed at its first formation. I hope that running my head against stone walls is not a weakness to which I am very liable, and in whatever way the best interests of the Association may now seem to lead, I shall be happy to go. The question is, what are trade questions? The business of a pharmacist, as distinguished from the profession of pharmacy, has now become of a rather miscellaneous character. In all but a few cases, and those confined to our large towns, necessity has compelled the pharmacist to deal in many things, not strictly, and sometimes not at all, of a medicinal character. With regard to these he must be considered as an ordinary trader, and so far as these are concerned must take his chance in the keen struggle which competition has produced. No question relating to these matters can be thought to have any relation to the objects of our Association. Then comes a debatable ground in which medicinal substances, in the preparation of which the pharmacist has no part, and the very composition of which he may not know, are included. The claim of the pharmacist to the exclusive right of dealing in these bodies is one which I fear the Government will be slow to acknowledge. I refrain from entering into the question of the relation of the Government to patent medicines, though it is one on which I have a strong opinion. I consider it as one within the province of this Association to discuss. One thing I do hold, that, as the only justification for governmental interference in any branch of industry is the prevention of injury to the subjects of that Government, it is for those who ask for such interference with regard to the sale of any article, to show that by making them responsible for injury done by careless or improper dealing, a safeguard against such injury will be provided. The point is, would they like to be so responsible for articles of the exact nature of which they are ignorant?

The case is different with the profession of pharmacy. The compounding and sale of legitimate medicines are matters which the Legislature has declared should be in the hands of properly qualified persons, and in these respects, I hold that Government should afford the most absolute protection to such persons. I would make no distinction between poisonous and non-poisonous substances. No such distinction can be made any more than, for example, between animal and vegetable life. The only line is that any drugs mentioned in the Pharmacopœia shall be sold, or any compound of them directed by a medical man shall be made up, only by a person possessing the qualifications which the Government has considered sufficient. This, I think, pharmacists have a right to ask, and more I do not think that they will get.

Then with regard to the relations of pharmacists to one another. I fear that I may not be quite in accord with the opinions of some of you when I say that I would deprecate attempts to make a trade union of this Association. You must give liberty to each one to carry on his business as seems best to himself. You cannot enforce uniformity of prices or times of closing, and all attempts to do either have, in my experience, whether among pharmacists or others, been utterly futile. Men will be found, who, under the pressure of pecuniary needs, will break any agreement, and it must be left for the slow advancement of public feeling, and the bold example of those who are strong enough, to bring about reform. Much may be done by private agreement; but after all, the service of the public will regulate the arrangements of those who live by it, and the higher education of the public will bring about a more thorough appreciation of the chemist's services and a more generous recognition of his claims. But for this the chemist must keep up a high standard. The more he becomes a mere trader the more he will be treated as such, whilst a men whose knowledge and skill have become known will be looked upon as one who must be judged by another rule. People do not object to pay a clever doctor a high fee, and if I may judge from my own experience, they are willing to pay something extra to a chemist of standing and ability. So I must urge the necessity of higher training for the chemist, more complete knowledge of all that relates to his calling, and of things that have any reference to it, that men may recognize in him something superior to a mere trader and feel that he is a member of the profession of medicine.

This may seem transcendental advice, too high and sublime for common things, and not fitted for the requirements of everyday life, but I may remind you that analytical chemists have very much the same difficulties to struggle with as their pharmaceutical brethren. We are not as yet afflicted by having analyses made at stores, but some of our branch of chemistry think that to offer to do analyses at half-a-crown is a shorter way to success than the acquirement of a thorough acquaintance with the science of chemistry and of everything which can be pressed into its service. I think differently, and have no desire for any outside aid, being satisfied to leave the issue to the decision of a public which is daily becoming more enlightened.

But to leave these matters of money and money-making, important as they are, because I do not think this Association can do much directly to affect them, I would rather rest my invitation to those outside to join us and to those who are members to take a more active part in its proceedings, on the ground of the pleasure which the acquisition of knowledge gives to its possessor, and on that of the duty of him who has to impart to others who have not. This is a giving which does not impoverish the giver, but, on the contrary, increases his store.

The increase of our knowledge, especially of those matters which come within our own department, is a duty which we owe to our higher nature. To starve the intellect for want of daily food is as suicidal to our best interests as to starve the body is for our natural body. Neither can thrive without constant supplies from without, and in each case suitability of food is as important as abundance. Each man knows his own need, and the aim of our Association is to provide such mental food as chemists require, in the first place. Still, variety is almost as important in mental food as in material, and we shall welcome occasional papers on subjects allied to, though not directly bearing on, our main object. We must never forget that we are an Association, and that we need the aid of all. I fear that some of our members neglect the assembling of themselves together, and make, as an excuse for non-attendance, that they can read the papers when they appear in the *Pharmaceutical Journal.* But this is not all the benefit that might be derived from them; the discussions often languish for want of members, and the reader is discouraged by the absence of sympathetic auditors.

Another reason why I hope that our numbers may increase is, that pharmaceutical education may be made a reality in Liverpool. I do not think Liverpool will have done its duty in this respect until it shall be possible for a student to qualify himself to pass the Minor examination without going to London. In many cases, pecuniary reasons render a prolonged residence in the metropolis an impossibility, and young men are forced into the crammer's arms. I commend to the members the attentive study of the address of Mr. Michael Foster at the late distribution of prizes. If his views are correct, more rigid regulations will naturally be instituted with regard to regular courses of instruction. It is no use to say that pharmacy will not be worth the trouble of all the study and labour. There must be pharmacists, and in these days when the question of "What must we do with our boys?" is so prominently brought before us, there will be candidates found for any and every means of getting a living. The matter for us to decide is, in what way can we aid in smoothing the way to the requisite knowledge by diminishing the expense and increasing the facilities for its acquirement? A School of Pharmacy of some kind has been on adjunct of the Association from its early days, and we must try to make it such a reality, that when attendance at regular courses of instruction becomes imperative, we may be able to point to our school as one worthy to be reckoned among those whose curriculum is as extensive as the requirements of the examination, and whose teachers will command the acceptance of the central authority. I may remind you that the Pharmaceutical Society has formulated its views on this point in a recommendation that candidates for the Minor examination shall have attended courses of lectures on chemistry, botany, and materia medica, and also a course of practical chemistry. Further, that the Council shall at its discretion recognize and accept certificates from certain public schools of science, and second, "other schools in which it shall have been proved to the satisfaction of the Council that the teaching is of sufficient excellence in kind, and of the scope indicated in the syllabuses."

Since writing the above, I find in the *Pharmaceutical Journal* of October 6, 1883, that the Council has taken a further step in the direction of carrying out its resolutions in favour of a definite curriculum of study by appointing a committee to frame bye-laws with reference to them.

Another reason why all our members should endeavour to induce others to join their ranks is that the efficiency of the library may be kept up and increased. We possess a library which contains many most valuable books on chemistry and botany, such as cannot be met with in any other lending library in town. Even the Free Public Library does not place before its readers many such works, and to the student it is most important that he should not be restricted to the study of such books of reference at one building in defined hours, but that he should be able to take them away with him to his home and there thoroughly make their contents his own. But of all books scientific works are soonest out of date, new editions should be got, and the possession of sufficient funds is all that your Council asks to keep the library up to the present position of science.

If we leave our own sphere and look at the world around us, the revision of the Pharmacopœia is one which has attracted much interest. Whether the pharmacists should be associated with medical men in the preparation of the new book, as is the case in America, is a question which it seems to me admits of only one answer. The President of the Pharmaceutical Society has expressed his opinion that that answer will be given, and that pharmacists will be represented. As an outsider I may be forgiven if I make one suggestion, namely, that as every student is expected to know his Pharmacopœia by heart, it will be well to remove all useless matter and to limit it to the absolutely needful. I mean that the preparation of such things as quinine, morphine, strychnine, etc., is not matter with which a pharmaceutical student will ever have to deal. These things cannot be made on the small scale, and it is hardly likely that the exact processes by which these bodies are commercially obtained in such beauty and purity will be revealed by their manufacturers. The student has quite enough to learn in regard to indispensable subjects, and a thorough knowledge of those things which he will have to deal with is far better than a partial acquaintance with those of which he will never think again when the examination is over.

I must now conclude this address with my most earnest appeal to all to do what in them lies to make this session a successful one, and this Association a real benefit to all in any way connected with it. Your Council will hail with gratitude any suggestions for its improvement, and what I can do shall be done. Remember what pharmacists have done in the past; in your ranks were Scheele and Pelletier, and now there are names which will be familiar to you as those of men who have shown that the highest attainments in science have not been antagonistic to the diligent and successful prosecution of their calling. Emulating their example, do not limit your ambition to the attainment of money, but resolve that your titles to respect shall include your reputation for knowledge, first of your own calling in all its aspects, scientific and practical, and then of whatsoever departments of the world of mind or matter you may have chosen for a bye-study, that so you may justify your claim to be considered members of a liberal profession, and enlarge your powers for usefulness and aid to your fellow-men.

Mr. A. H. Mason, in moving a vote of thanks to the President, expressed his appreciation of the views enunciated.

In this he was joined by Dr. C. Symes, who seconded the vote of thanks, and by Messrs. Woodcock, T. Fell Abraham and Conroy, who supported it cordially.

The motion was put to the meeting by the Vice-President; Mr. A. H. Mason, and carried by acclamation.

EDINBURGH CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

The first meeting of the sixth session was held in the Pharmaceutical Society's rooms, 119a, George Street, Edinburgh, on Wednesday evening, October 17, at 9.15, Mr. C. F. Henry, President of the Association, in the chair.

There was a large attendance of members and others, including Messrs. Ainslie, Nesbit and Stephenson, members of the Council of the North British Branch of the Pharmaceutical Society.

The minutes of the last meeting of the previous session and those of a special meeting held during the recess having been read and confirmed, the President then proceeded to deliver the Inaugural Address.

After some preliminary personal remarks, Mr. Henry proceeded to say that trade rather than scientific questions were at the present time prominent, and referred to the fact that at the last meeting of the British Pharmaceutical Conference, Professor Attfield had departed from the usual course and devoted the whole of his presidential address to the consideration of a political subject. Mr. Henry thought he could not do better than follow so worthy an example, and draw attention to that address and the criticisms it had evoked. He then proceeded to give an epitome of Professor Attfield's address, interspersed with a running commentary, and at the close raised the question as to who should be blamed for the condition of affairs disclosed in it. Excluding from blame the pharmacists and the State, he came to the conclusion that the whole blame lies with the public. He said, "the public demands cheap drugs and therein lies the reason why so many miscellaneous tradesmen deal in drugs. What the public demands, the public will always find some one ready to supply. If the public, or rather those members of the public who support the trade in these cheap drugs, would do justice to themselves and act as they ought to act by purchasing their drugs only from those qualified to determine their purity and value, there would be no necessity for any extension of the Pharmacy Act at all." In the actual state of affairs, however, Mr. Henry endorsed Professor Attfield's opinion as to the remedy to be found in securing further legislation and referring to the draft Pharmacy Bill, he said, "Great hopes were entertained of it, but, alas, these have been sadly disappointed, and unless next session it receives better treatment pharmacists will require to agitate for a change amongst some of the workmen and an introduction of new machinery into the Parliamentary mill. It is to be noted, however, that that Bill comes far short of the requirements of the case made out by Professor Attfield, and a new Bill embodying the provision that not only the sale of poisons, but of all drugs used internally, at any rate, shall be restricted to registered and qualified chemists," should be drawn up. In the meantime he thought that chemists themselves might do something by the establishment of committees to regulate the prices in different districts. This would, he believed, act in the interest of the public by tending to foster a competition as to quality rather than as to price. In conclusion, Mr. Henry passed in review the various criticisms upon Professor Attfield's address that have appeared in the public press.

Mr. W. S. Turnbull, Vice-President, moved a hearty vote of thanks to Mr. Henry for the manner in which he had addressed the Association, and hoped that the address would be fully considered and discussed by the members, not only at this, but at future meetings of the Association, as it was a subject in which they were all materially interested. Referring to the presence of the President, and other well-known members of the North British Branch, to whom they were greatly indebted for their kindness, he had much pleasure in calling upon them for a few words of counsel and advice.

Mr. Nesbit congratulated the Association on the very able address to which they had just listened. He was pleased to see that the members turned out in such large numbers, and hoped they would continue to do so during a session which promised to be one of great interest. He would not attempt to criticize the address. Professor Attfield had treated the subject in a manner which could not fail to exercise great influence. He referred to the position in which the pharmacist was placed in being compelled by Government to undergo examination and registration, and getting so little in return. He believed that the duty of the pharmacist at the present time was to try to show the public what was its real interest in the matter.

Mr. Ainslie expressed his pleasure at being present at such a large and successful meeting. He believed that by taking advantage of this Association, assistants and apprentices would derive great benefit. He was glad to see from the syllabus that papers of so much interest were promised, and those who entered heartily into the work could not fail to find that they had greatly improved themselves by the end of the session. He could assure them of his deep interest in the Association and wished them every prosperity.

Mr. J. B. Stephenson said that this was not the first time that he had attended the meetings of the Association; he had been a frequent visitor and he knew that they were having much success and doing good work. He could assure them that anything he could do to further its interests he would do with the greatest pleasure. It was a happy thought on the part of Mr. Henry to choose Professor Attfield's address as the groundwork of his paper. He had had the pleasure of listening to the address at Southport, and much that he had heard that night had tended to revive and quicken many deep impressions which it had made.

Mr. Henry proposed that a hearty vote of thanks be given to those members of the North British Branch who had favoured the Association with their presence.

Mr. Hills seconded the motion. In speaking of the position of a pharmacist, he said it was not generally understood what a profession really meant; every calling was a profession, but what the chemist claimed was, that he had undergone a scientific training which entitled him to rank among the learned professions.

The discussion was continued by Messrs. Dunlop, Low, McEwan and Simpson.

The vote of thanks was passed unanimously.

The President having made some remarks regarding the subject of the papers promised during the session and intimated that the next meeting would be held on November 7, the meeting adjourned.

ABERDEEN CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

The inaugural address of the ensuing session of this Association was delivered on Friday, October 19, by the President, Mr. Patrick C. Smith.

The subject treated of was "The Present of Pharmacy: What it teaches of its Future." The lecturer expressed his opinion that pharmacy was at present in a state of transition, and that at no distant date it will take a very different position from the one it now occupies.

At the close a vote of thanks was accorded to the lecturer.

The office-bearers for the session are:—President, Mr. Patrick C. Smith; Vice-President, Mr. J. C. Kidd; Secretary, Mr. G. D. Bowie; Treasurer, Mr. W. C. Angus; Members of Committee, Messrs. Anderson, Craig, Mathieson, McKenzie, Moir, Paterson, and J. Smith.

The syllabus for the session includes a variety of interesting items, including a lecture from Professor Brazier, of Aberdeen University.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

(*Continued from page* 339.)

The next paper was on—

Note on the Processes of the British and United States Pharmacopœias for the Determination of Hydrocyanic Acid.

BY LOUIS SIEBOLD.

The members of this Conference will be aware that the two processes to which the title of this paper refers differ in two essential points. In the first place, the conversion of the acid into a cyanide is effected in the B.P. process by means of sodium hydrate, while the United States Pharmacopœia directs magnesia suspended in water to be used for the same purpose. The second and chief point of difference consists in the manner in which the decinormal solution of silver nitrate is applied. According to the B.P., this solution is to be added until a permanent precipitate of silver cyanide just begins to form, or in other words until the whole of the sodium cyanide has been converted into the soluble double salt $NaAgCy_2$. The process of the United States Pharmacopœia does not stop at this point, but directs the addition of the silver nitrate solution to be continued until the soluble double cyanide (in this case $MgAg_2Cy_4$) is again completely decomposed, or until the whole of the cyanogen present has been precipitated as silver cyanide. As this process is conducted in the presence of a small quantity of neutral potassium chromate, the end of the reaction is distinctly indicated by a red coloration due to the formation of silver chromate. A mere glance at the equations illustrating this process suffices to show that it requires exactly twice the volume of silver nitrate solution required by that of the British Pharmacopœia; but, strange to say, this fact seems to have been overlooked by the compilers of the United States Pharmacopœia. This serious error in its statement of the volume of silver solution required for a given weight of the acid to be tested has been already pointed out by Mr. R. A. Cripps, in a paper read before the School of Pharmacy Students' Association; and I can, therefore, at once pass on to the main object of this note, viz., the discussion of the question whether this process is in itself a good one, and whether or not it compares favourably with that of the British Pharmacopœia. Mr. Cripps, in the paper alluded to, speaks of it as less satisfactory; but gives no reason for his unfavourable opinion, except the fact that the process requires a larger quantity of silver solution. But this feature seems to me an advantage rather than otherwise, for the larger the volume of a test solution required for the analysis of the same weight of substance, the greater must be the accuracy in the result, provided the method itself is free from inherent defects and is not inferior in the delicacy of its reactions. I have therefore tested this method for its accuracy and can report to this meeting that, if properly conducted, it is thoroughly reliable, and certainly in nowise inferior to the process commonly used in this country. Indeed, in the hands of inexperienced manipulators, it appears to me the preferable one of the two. It does, however, require certain precautions, to which I desire to draw attention.

(1) Care must be taken that a sufficient amount of magnesia be used, for otherwise the results will be too low and entirely untrustworthy. The cause of the inaccuracy in this case is the same as that which renders the British official process fallacious in the presence of an insufficient amount of soda, as pointed out in my paper read before the Conference meeting at London ('Year-Book of Pharmacy,' 1874, p. 565). An excess of magnesia, however, is less injurious than an excess of soda in the other method and does not appreciably affect the accuracy of the result.

(2) The magnesia used must be free from chlorides, and the hydrocyanic acid free from hydrochloric acid; otherwise the results will be too high. Both should, therefore, be tested for these impurities. It will be remembered that hydrochloric or other mineral acids are sometimes added to hydrocyanic acid with the idea of increasing the stability of the latter. The simplest mode of detecting such an admixture would be to boil some of the hydrocyanic acid for some time until this volatile acid is completely expelled and then to test with silver nitrate.

If these precautions be duly observed, the results of the process are all that can be desired.

At the conclusion of the paper,

Mr. Siebold added—In a paper on the estimation of hydrocyanic acid by Liebig's method, read at the Dublin meeting of the Conference, I pointed out that the same process might be advantageously employed for alkalimetric purposes, inasmuch as the volume of silver nitrate solution used in the titration indicates the proportion of alkaline cyanide present, but not a particle of any free hydrocyanic acid that may occur in the solution in consequence of the use of an insufficient amount of alkali. In the presence of such an excess of hydrocyanic acid, only the portion actually combined with alkali is indicated, and hence the proportion of alkali which has entered into combination with the acid may be as readily calculated from the volume of the silver solution required as that of the cyanogen. In the paper alluded to I explained the various advantages of this process over the usual methods of alkalimetry, and showed that alkaline carbonates can thus be accurately determined at an ordinary temperature with the same ease and precision as caustic alkalies. It is a noteworthy fact that, whereas, hydrocyanic acid is incapable of decomposing alkaline carbonates, the decomposition is brought about in a most complete manner and without the aid of heat in the presence of silver nitrate, owing to the great tendency of hydrocyanic acid to form soluble and perfectly neutral double cyanides of silver and alkalies. While engaged in my recent experiments with the United States Pharmacopœia process for determining the strength of hydrocyanic acid, the use of magnesia in the place of soda, as directed in that process, suggested to me the probability that even the carbonates of the alkaline earths may be decomposed by hydrocyanic acid in the presence of nitrate of silver, and that this titration might perhaps also with advantage be extended to their determination. Experiments in this direction are now in progress, and the results will be communicated in due course.

The President said, considering the importance of hydrocyanic acid as a remedy, and its highly poisonous character, every contribution to existing knowledge respecting tests for this substance must be welcome, and the Conference would, therefore, appreciate Mr. Siebold's work in that direction. Mr. Cripps had stated that it was only his impression that the one process for estimating the strength of hydrocyanic acid was preferable to the other, and that he intended to continue his work. He had no doubt he would do so, unless he saw that the matter was already in excellent hands. He was very glad to know that Mr. Siebold was carrying on his researches into these reactions in the direction he had indicated, and the result of those researches, whatever it might be, would be most welcome.

A vote of thanks was passed to the author.

Mr. John Williams said he had for a great many years paid some attention to this question of hydrocyanic acid testing, and had always looked upon it that Liebig's test, at present recognized by the British Pharmacopœia, was a very great advance over any previous test, because neither hydrochloric acid nor any other mineral acid interfered with it. He considered that the process now given in the American Pharmacopœia, in which magnesia was used, was a distinct retrogression, going back to the days before Liebig's genius had discovered the beautiful test which had been applied so successfully to hydrocyanic acid. The truth was that the hydrocyanic acid of commerce always did and must contain a preservative of some kind, and that preservative was generally hydrochloric acid. If prepared without that it would change so rapidly and continuously that it would never be reliable after being kept for a very short time. The cause was easily explained: there was ammonia in the atmosphere and alkali in the glass of the bottle, and any alkaline condition whatever rapidly caused this change and the destruction of the hydrocyanic acid; therefore, the addition of a small quantity of a mineral acid ought not to be looked upon as in any way an adulteration, but simply as a preservative, and as such it was most valuable; but it was most important that there should be a test by which the hydrocyanic acid itself and its strength could be determined without reference to this mineral acid put in as a preservative. That was done in the present B.P. process, and would not be done by the new American test. Therefore, he entirely contended against the adoption of the American test in preference to that now used. It might be contended that hydrochloric acid ought not to be put into hydrocyanic acid; but that was another question altogether, and his experience was that it was necessary to add either that or glycerine, or some other substance to act as a preservative.

Mr. Dott thought it was unnecessary to boil off the hydrocyanic acid in order to test for hydrochloric, because cyanide of silver was soluble in nitric acid, whilst chloride was not.

Mr. Naylor had always felt extremely nervous in using Liebig's method for the determination of hydrocyanic acid, and for the last two or three years had entirely abandoned the method for the one suggested by Dr. Hannay. In that process mercuric chloride was used, the only objection to which was the instability of the volumetric solution of mercuric chloride.

Mr. SCHACHT said he had hoped to hear further explained the exact reason why Mr. Cripps found the United States Pharmacopœia process objectionable, and that the reason would have been the comparative difficulty of determining the moment at which the chromate of silver began to fall. His own experience he did not profess to be equal to that of the scientific chemists around him, but was merely that of a pharmacist who systematically endeavoured, before allowing his dispensing bottle to be filled with dilute hydrocyanic acid, to be quite sure it was of the proper strength, but so far as he had tried it he had been perfectly satisfied with the British Pharmacopœia process. The smallest particle of a drop of the nitrate of silver solution would certainly show the moment at which the operation must cease, and the most delicate determination of the strength of the solution was in that way easily arrived at. On the other hand, when he had attempted to estimate with chromate he had found that that exact particle of a drop in the experiment he could not arrive at nearly so easily. The first deposit of chromate of silver he generally found required a little time. He would not say the process was not accurate, but it was certainly not so instantaneous. He had always to give a little repose to the solution before the first evidence of the chromate of silver appeared, so that in his hands the process never arrived at that beautiful delicacy which was obtained by the British Pharmacopœia process.

The PRESIDENT asked Mr. Schacht if he had found it necessary not only to render the mixture alkaline, but to maintain its alkalinity.

Mr. SCHACHT said he had observed that point most carefully since attention was directed to it by Mr. Siebold, who pointed out that it should be just in excess of the quantity which was ultimately found necessary to convert the whole hydrocyanic acid into alkaline cyanide.

Mr. TANNER said he could corroborate what Mr. Schacht had stated with regard to the difficulty of determining the end of the reaction when chromate of potassium was used. It appeared to him absolutely necessary that a considerable time should be allowed to satisfy oneself that the reaction was perfect; not so with regard to Liebig's process. The determination there was sharp and decided, and there was no doubt left in the mind of the operator when the end of the process was arrived at. It was very necessary to take the precaution that the solution should remain alkaline, but it was also necessary that it should not contain too great an excess of alkali.

Mr. A. C. ABRAHAM said, some few years ago a paper appeared in the *Pharmaceutical Journal*, in which it was stated that the quantity of alkali was of great importance. Liquor sodæ was a cheap thing, and there was no fear of not using enough if they knew it was necessary; but if one got false results by using too much it was of great importance. The next time, therefore, he had occasion to test this preparation he made several experiments; he used 10 cubic centimetres of hydrochloric acid, 10 cubic centimetres of liquor sodæ, and got a certain result; then he used double and treble the quantity of liquor sodæ, and the results were practically absolutely identical, showing that there was no fear of getting false results by using anything like moderate excess. Ten cubic centimetres were considerably more than was required, but that was the quantity he used to the best of his recollection. One objection to the Pharmacopœia process had not been alluded to, which was common to all the volumetric tests of the Pharmacopœia; the quantities used were directed to be taken by weight, and those quantities were inconvenient. It would be much more convenient if the direction was to take, say 10 cubic centimetres of a liquid requiring so many cubic centimetres of a volumetric solution, and would save an immense amount of trouble. He had calculated out the quantities in this way for the Pharmacopœia estimations, and found it amply repaid him for the trouble.

Mr. WHITLEY WILLIAMS said, in making titrations with a nitrate of silver solution in which chromate of potassium was used as the indicator, he had usually found that the degree of neutralization of the fluid mattered very little if the alkali present happened to be bicarbonate. The ordinary alkaline bicarbonate of soda or potash might be in any reasonable excess whatever, in fact in excess far beyond what any one would think of using, without danger. He thought the use of magnesia in the American process was quite a chimerical advantage.

Dr. SYMES thought there was some little contradiction between the statement of Mr. Tanner that an excess of alkali was prejudicial to the result, and that just made by Mr. Abraham, but he thought Mr. Abraham must have started with a large excess, and having done so his results would probably correspond when he had a little larger excess. If he had prepared it with the bare quantity necessary, and then with the soda in very large excess, he was inclined to think the results would be different.

Mr. A. C. ABRAHAM said he had used smaller quantities, but still the results were the same.

Mr. SIEBOLD said he perfectly agreed with Mr. Williams in everything he had said; and if that gentleman's remarks seemed to contradict some of the statements in his (Mr. Siebold's) paper, such contradiction was only an apparent and not a real one. He did not wish by anything he had said to replace the B.P. process by that of the United States Pharmacopœia; he had simply tested the relative accuracy of the two methods and had arrived at the conclusion that, if the precautions he had named were properly observed, the results of the U.S.P. process were at least as accurate and trustworthy as that of the British Pharmacopœia. It was certainly an advantage in the latter that the presence of chlorides did not interfere; but on the other hand the larger volume of silver solution and the use of magnesia in the place of soda might fairly be considered as compensating advantages. How greatly the use of an insufficient proportion of soda impaired the result he had amply shown in a previous paper, as well as the extent of the inaccuracy brought about by an undue excess of alkali. Having the injurious effect due to both causes in his mind, Mr. Naylor said he had always used the B.P. process with a certain amount of nervousness; but he (Mr. Siebold) did not think there was any real cause for that, since mere testing with litmus paper at the end of the titration would at once settle the question whether or not an insufficient amount of alkali had been used, and as regards an excess of the latter, the inaccuracy of the result due to this cause was so trifling that, for all practical purposes, it might be ignored, unless the excess of the alkali used was unreasonably large. The use of magnesia, however, in the place of soda, as directed in the American process, would entirely remove this last-named source of error. Mr. Dott remarked that it was unnecessary to boil off the hydrocyanic acid in order to test this acid for hydrochloric acid, as the silver precipitates of the two acids behaved differently towards nitric acid. But as silver cyanide was only soluble in strong boiling and not at all in cold dilute nitric acid, he (Mr. Siebold) did not consider this difference as affording a satisfactory means of detecting hydrochloric in hydrocyanic acid. The difficulty of observing the first change from yellow to red, which Mr. Schacht had experienced in titrations with silver nitrate where potassium chromate was used as an indicator, had never given him any trouble; but he knew of others who had the same difficulty. This might be accounted for by the difference in the degree of sensibility towards slight colour changes in the eyes of different observers.

Mr. A. C. ABRAHAM asked whether cyanide and other impurities were not liable to be found in commercial soda, which might have produced the discrepancy some people noticed.

Mr. SIEBOLD said he had performed all his experiments with pure sodium hydrate and did not know to what extent commercial caustic soda might be contaminated with cyanide, the presence of which would certainly impair the result.

A paper was then read entitled—

Iodine in Cod Liver Oil.

BY EDWARD C. C. STANFORD, F.C.S.

"It is proposed to verify the statement in Garrod's 'Materia Medica' that cod liver oil contains 0·06 per cent. of iodine." See "Blue List."

If this statement were true cod liver oil would be one of the richest sources of iodine with which we are acquainted. At present the marine algæ form the only commercial European source of iodine. The largest quantity of iodine found in the deep sea tangle or stems of *Laminaria digitata* amounts in the fresh plants to about 0·1 per cent. The quantity obtained when this plant is burned into kelp seldom reaches 0·05 per cent. The average yield from laminaria drift on the large scale is 0·025 per cent., but many thousands of tons of seaweed have been made into kelp and worked for iodine, which have not yielded more than 0·005 per cent., and some even less than this, so that we have to deal on the large scale with a material, and constantly to test samples, containing very small percentages of iodine. I mention this in connection with the process daily employed for many years in estimating small amounts of iodine in our laboratory, and which has also been employed in obtaining the results from cod liver oil to be published in this paper.

Much difference of opinion has arisen amongst former observers with regard to iodine in cod liver oil, and the statements of results are extremely conflicting, some chemists having failed to find iodine at all, others only in some specimens of this oil. Other chemists again have estimated the proportion of iodine as much higher than the quantity above indicated; and it has been assumed that this element represents an important factor in its medicinal value.

In a well known work on materia medica the editors remark that the state of combination in cod liver oil "may, perhaps, tend to develop a peculiar action of iodine and bromine, and endow them with an efficacy not otherwise attainable."

The following results have been published at various times by the authorities quoted:—

	Iodine per cent.
Dorvault found in cod liver oil . . .	0·150
Kaie found in cod liver oil	0·180
Joseph found nearly ½ per cent. . . .	0·487
Machenroden found	0·162 to 0·324
Grager found in light brown oil . . .	0·0846
Dr. de Jongh found in pale oil . . .	0·0374
„ „ pale brown . . .	0·0406
„ „ brown	0·0295

All these are extremely high and improbable.

Mr. Mitchell Bird (*Pharm. Journ.*, [2], i., p. 546) gives results of analyses of six varieties of cod liver oil, which are much nearer what I believe to be the truth. The method and the results differ considerably from mine, although we are both agreed in the fact that we have found iodine in all the specimens examined.

The percentage results are as follows, the iodine being calculated as potassium iodide:—

	As KI		As Iodine.
1. Cod liver oil, Norway . .	·0021		
2. Cod liver oil, Norway . .	·0018	average	
3. Cod liver oil, Norway . .	·0016	·001775	·001355
4. Cod liver oil, Norway . .	·0016		
5. Cod liver oil, Newfoundland	·0012	average.	
6. Cod liver oil, Newfoundland	·0014	·0013	·000993

He used 5000 grs. of the oil for each experiment and saponified with alcoholic solution of caustic potash, burned the soap formed and dissolved out the salts; after saturating the solution with sulphuric acid and separating the potassium sulphate deposited, he employed the starch test, setting free the iodine with nitrite of potassium and sulphuric acid, and comparing the colour with standard solutions of potassium iodide. My method is different; it is a delicate process of very general application and one that I adopted some years ago, having discarded all others in its favour. I will describe it here as applied to kelp, one of the most troublesome and various of all commercial substances to sample and test.

To insure an accurate sample about 100 lbs. are carefully picked from a cargo of say 100 tons, and ground up. Of this 100 grains are taken to estimate the moisture, and another 100 grains to estimate the soluble matter, the potash and the iodine. The kelp is treated with about 4 ounces of hot water, which dissolves little or none of the oxysulphides; this operation is repeated, the residue washed, and the solution made up to 5000 grains measure. Of this one-tenth part or 500 grains measure, equal to 10 grains of kelp, is taken for estimating the iodine, so that we never operate on more than one-tenth of a grain of iodine, generally one-twentieth, often one-hundredth. In fact, if the amount present exceeds one-tenth of a grain, we always dilute the solution. One hundred grains measure of bisulphide of carbon are added, and a few drops (1 to 3) of nitrosulphuric acid* dropped in. The testings are performed in large even tubes and compared with graduated standard solutions of potassium iodide treated in the same manner. By this method $\frac{1}{2500000}$th part is easily detected and measured, and up to $\frac{1}{1000000}$th part the estimation is very accurate. If the iodine in a seaweed or other organic substance is to be determined, it is carbonized in a small iron retort or crucible, and the charcoal treated in the same way. Burning to ash, however carefully done, involves a considerable loss of iodine, more than is generally supposed. For instance, a sample of seaweed ash exposed for twenty-four hours in an open crucible over an ordinary Bunsen burner will not retain a trace of iodine at the end of that time. We invariably carbonize the material in preference to burning to ash, in order to retain all the iodine and to easily extract the salts. Some of these specimens are extremely difficult, indeed, almost impossible, to burn to complete ash, on account of the large proportion of fusible salts present. In estimating the small quantities of iodine necessary in our analyses we are really limited to colour tests. I have long discarded starch, as it introduces an organic substance very liable to change, and in many circumstances unreliable. Moreover, in my hands it is not so sensitive as that with bisulphide of carbon. The solution is not perfectly transparent, and the indications not so sharp. The colour is spread over the whole liquid, and when dilute can only be seen by looking down the length of the tube, whereas in the bisulphide of carbon test it is removed out of the solution and concentrated in a sixth of the volume at the bottom of the tube. The comparison of the two methods is very marked. In testing a solution of potassium iodide containing only $\frac{1}{2500000}$th part of iodine, the maximum effect is immediate, and another advantage is that the iodine can be easily separated from its solution in bisulphide of carbon. We usually recover the latter by treating it with zinc in the presence of water. The specimens of cod liver oil experimented on, for which I am indebted to our mutual friend and former President, Mr. Reynolds, were taken in quantities of 5000 grains each, saponified with 1000 grains of caustic soda, pure and free from iodine, then carbonized in a large porcelain crucible; the resulting charcoal was treated with hot water and made up to 5000 grains measure. One-tenth of this or 500 grains was found quite sufficient to detect the presence of iodine and to estimate it. Three experiments were made, taking 500 grains, 2500 grains and 1000 grains respectively, with pretty concordant results. The mean results are appended.

In the first experiment the solution was tested at once in the manner indicated. In the second the solution

* The nitrosulphuric acid is made by treating starch with nitric acid, and passing the nitrous fumes into sulphuric acid, 1·843 sp. gr. to saturation. The mixture keeps very well.

was neutralized with hydrochloric acid in the presence of the carbon bisulphide, no iodine was eliminated until the nitrosulphuric acid was added. In the third the solution was neutralized with hydrochloric acid before the addition of the test solutions. Little difference was noticed. The following six specimens were selected:—

No. 1. Cod liver oil, pale.
No. 2. Cod liver oil, Norway.
No. 3. Cod liver oil, manufactured by Carr and Sons, Berwick-on-Tweed.
No. 4. Cod liver oil, English.
No. 5. Cod liver oil, Newfoundland.
No. 6. Light brown cod liver oil.

The mean proportions of iodine found were per cent.—

No. 1.	0·000410	Mean percentage of iodine. 0·000322.
No. 2.	0·000434	
No. 3.	0·000276	
No. 4.	0·000138	
No. 5.	0·000315	
No. 6.	0·000360	

I also estimated the iodine in fresh cod liver; the fishmonger informed me that it is not yet in season, but the result is here appended. Five thousand grains were treated in the same manner as the oil. Having stated on a former occasion (B. Pharm. Conference, Liverpool) that the oil vomited by the fulmar (*Fulmaris glacialis*)* of St. Kilda, and which, though obtained from a bird, has the reactions of a fish liver oil, contains iodine, I have also estimated this amount. Five thousand grains were treated in the same way as the cod liver oil.

Cod liver oil dragées are stated to be made of cod liver from which the oil has been removed; an analysis of these is also appended. One thousand grains or 173 of the dragées were employed saponified and with 200 grains of caustic soda. These are extremely rich in iodine, and would form a valuable source of that element if they can be procured cheap enough to contend with the present low prices. I notice, however, that a box of 250 dragées sells at 5*s*., and is considered (by the maker) to be equal to 6 pints of oil, so that the quantity employed would be equal to 83 ounces or 36,312 grains, or about seven times the quantity of oil used in the other experiments. It contains one hundred and eighty seven times the proportion of iodine.

	Per cent.
Fulmar oil contains iodine	0·000095
Cod liver fresh contains iodine . .	0·000817
Cod liver oil dragées contain iodine .	0·056366†

It will be noticed that the fresh cod liver contains more than double as much iodine as the mean percentage in the oil. Mr. Gate has kindly sent me an estimate of the yield from his experience of ten years' average of oil from cod liver; it is about 45 per cent., taking the best time, December. The inference is that the liver without the oil would contain a much higher percentage of iodine, as shown indeed in the dry dragées. And I shall not be surprised to find as much in the fish. This point is under investigation.

Scotch herring has been said by "Jonas" to contain iodine, and this is also under investigation.

This morning I have received the results of the analysis of fresh cod, herring, and herring brine.

5000 grains of fresh cod were treated with .	500 grains caustic soda.
‡5000 grains of salt herrings were treated with	" "
‡5000 grains of herring brine were treated with	" "

Fresh cod fish contained ·00016 per cent. iodine dry = ·000829.
Scotch herring salted contained ·00065 per cent. iodine.
" brine " ·00012 " "
The cod fish contained 80·7 per cent. water.

In the fresh cod fish the analyst for the first time in these experiments was troubled with a large quantity of sulphides, and in this case only was not satisfied with the indication from 500 grains measure, and was obliged to use the larger quantity.

It will be seen that the herring contains four times the amount of iodine contained in the cod fish, and more than in any of the samples of cod liver oil; if, therefore, the iodine be the medicinal element, you should recommend Scotch herring salted; it is very cheap at present.

I find the subject becoming interesting, and, indeed, alarming to the iodine maker, and intend examining other varieties of fresh fish, for I expect to find iodine in all, and, if so, every man who eats fish will become his own iodine eliminator. Specimens of true genuine unmixed whale, seal, and bottlenose oil have been sent me by my friend, Captain John Gray, a celebrated Peterhead whaler, to whom the Arctic regions are a kind of "Winter Garden," and these are under examination, but I cannot yet report the results.

Since the publication of the paper, the following results have been obtained, the respective oils having been treated in the same manner as the cod liver oil:—

	Per cent.
Whale oil, cold drawn, contains iodine	·00001
Bottle-nose " "	·00010
Seal " "	·00005

The PRESIDENT, in proposing a vote of thanks to Mr. Stanford, said it was very satisfactory that so great an authority on iodine should have attacked this subject, and handled it so thoroughly.

The vote of thanks was passed unanimously.

Mr. EKIN did not think the experiments Mr. Stanford referred to were necessarily antagonistic to the results of his experience with regard to the delicacy of the starch test, the conditions being so distinctly modified that they would more than account for any difference in result. It would be remembered that his experiments were directed to the detection of very minute quantities of nitrites in potable water, and the reverse conditions under which Mr. Stanford searched for iodine were very different. He (Mr. Ekin) found time an important element in the delicacy of the test.

Mr. STANFORD said he had no doubt that testing for nitrites with iodide of starch was an extremely delicate indication, but that was not so with the solutions he had to do with, the solutions for cod-liver oil being not unlike those ordinarily dealt with. No doubt in iodide of starch it was necessary to give some time, whereas in his experiments the results were immediate—in fact, they were rather tied up to immediate results.

A paper was next read on—

THE TREES YIELDING BENZOIN.

BY E. M. HOLMES, F.L.S.

The benzoin which enters into English commerce includes four varieties, named respectively Sumatra, Palembang, Penang and Siam benzoin. These exhibit certain characteristic appearances by which they are easily recognized, and three of them, namely, Sumatra, Penang and Siam benzoin, are probably derived from three distinct plants. The botanical source of Sumatra benzoin was determined by Dryander, and an account and figure of the plant were published by him in the *Philosophical Transactions*, for the year 1787, lxxvii., p. 303, but the trees which yield the other varieties have as yet never been identified with certainty. The Penang benzoin is similar in appearance to the Sumatra kind, but it has an odour which is quite distinct and resembles

---

* *Pharmaceutical Journal*, Nov. 1870.

† In the published analysis of these by Professor Garreau the iodine is estimated at 0·154 per cent., *i.e.*, richer than any other known organic substance.

‡ Two determinations were made, one with 500 grains and another with 4500 grains, and the mean taken.

that of storax. It is in all probability not produced by *Styrax benzoin*; but we have as yet no accurate information concerning the botanical source of Penang benzoin. The authors of 'Pharmacographia' point out that it may perhaps be the produce of *Styrax subdenticulata*, Miq., since this tree, which occurs in West Sumatra, has the same name, "Kajoe Kéminjan," as *S. benzoin*, and Miquel remarks of it *an etiam benzoiferum*? That these two species should receive the same native name in Sumatra is not surprising since the leaves are very similar in shape and appearance and the fruit of *S. subdenticulata* apparently only differs from that of *S. benzoin* in being obovate instead of globular and depressed.

Palembang benzoin resembles the Sumatra sort in odour and differs from it chiefly in its much greater transparency and in yielding, as I am informed, a larger percentage of benzoic acid. It frequently contains moisture and if recently imported specimens are placed in a bottle they soon become mouldy. Concerning the tree which yields Siam benzoin, nothing definite has hitherto been ascertained, although as long ago as 1859, Mr. D. Hanbury wrote to Sir R. H. Schomburgh, asking him to investigate the origin of the resin, and to find out whether the tree which yielded it was really *Styrax benzoin*. Nor have subsequent inquiries been more successful. The only account extant of the mode of collection of Siam benzoin is that given by Sir R. H. Schomburgh, who was British Consul for some years at Bangkok. He, however, never visited the region producing benzoin and could therefore only give information at second-hand. He represents that the bark is gashed all over and that the resin which exudes collects and hardens between it and the wood, the former of which is then stripped off. The authors of 'Pharmacographia,' remark that it is evident that all Siam benzoin is not thus obtained. Schomburgh adds that the resin is much injured and broken during its conveyance in small baskets on bullocks' heads to the navigable parts of the Menam river, whence it is brought down to Bangkok.

The state of our knowledge of Siam benzoin being thus imperfect, it occurred to me to write to Mr. R. Jamie, of Singapore, to ask him for information on the subject. This gentleman takes great interest in all that relates to pharmacy, and has, I believe, been a liberal contributor to the Museum of the North British Branch. A few weeks ago I received from him a box of specimens for the Museum of the Pharmaceutical Society, containing amongst other interesting and valuable donations some sections of the trunk of the Siam benzoin tree, and herbarium specimens of the leaves, but unfortunately neither flowers nor fruit; also specimens of the Sumatra benzoin tree with leaves, flowers and fruit. In addition to these specimens he has contributed some interesting information, which I have taken this early opportunity of laying befere you. With regard to the Siam benzoin plants Mr. Jamie writes:—

"My friend, Captain Hicks, of Bangkok, kindly procured them after very great difficulty from his friend living in the district where the gum benzoin trees are found, and he writes as follows:—'According to your request I had fifteen gum benjamin plants brought over from Suang Rabang, one of the northern Laos states tributary to the King of Siam, but after a deal of shifting and removing baggage on bullocks, twelve of them withered up; however, I have succeeded in getting three of them brought to Chung-mai; these I now send you. The one in the flower pot seems to be thriving remarkably well, but the other two in bamboo joints I have my doubts about. I also send you some sections of wood with the bark attached, and here and there you will find the gum sticking on the wounds and incisions made by the natives. The flowers, I am sorry to say, I could not get, as the trees have already flowered. From reliable information the tree is indigenous in all the northern Laos states, but grows luxuriantly in Suang Rabang and all along the belt of mountains in this province.'

"In the months of April and May the leaves begin to wither and fall off, and the natives then make incisions in the bark, and after a short time a lot of milky substance exudes and soon hardens; the gum then dries on the incisions and falls to the ground, which is swept daily and watched so that no earthy matter gets mixed up with it.

"The tree attains from 3 to 6 feet in circumference, and has a long trunk throwing out branches on the top; after six years' growth it can be bled. The flowers are attached to the small branches close to the leaves and begin to flower in June. The tree throws out shoots from the roots, and can be propagated by cuttings. The natives also say that after the flowers fall off, in a short time a lot of young plants spring up.* The gum is a considerable article of traffic, in fact a monopoly, fetching a good price in the Bangkok market. It is used generally for fumigating sick rooms and making scented water. Large quantities generally find their way to Bangkok, being brought overland on oxen to Sawaryaloke, Pitchai, and other Siamese provinces, and are exported to Europe by several mercantile firms."

Of the three young plants above mentioned, one was given by Mr. Jamie to the Curator of the Singapore Botanical Gardens to forward to Kew, a second was planted in Mr. Jamie's own garden, and the third died.

The twig which I now exhibit was taken by Mr. Jamie from the young plant in his garden. The specimen sent to Kew is still living and seemed to be in a healthy state when I saw it a fortnight since. Judging from the appearance of the plant at Kew and from the leaves sent by Mr. Jamie, the Siamese benzoin tree is probably a distinct species, although nearly allied to *S. benzoin*, Dry. The leaves are rather thinner, the lateral veins are fewer in number and the veinlets more prominent beneath, but it is necessary to wait until flowers and fruit are obtained before the exact species to which it belongs can be ascertained. Mr. Jamie has now the two growing together in his garden, and remarks in his letter, "Judging from what I have seen of the two kinds growing together, they are different."

I have compared the specimens of the Styrax benzoin tree from Mr. Jamie's garden, with Dryander's original specimen in the British Museum, and they correspond exactly.

Concerning this tree Mr. Jamie writes:—"The Singapore grown tree is thought to be from Palembang,† it is about 30 feet in height, and the branches are all at the top. The circumference of the trunk is from 14 to 16 inches. It flowers in March and the fruit does not take long to mature, then it falls off, producing seedlings in abundance at the foot of the tree. How old this tree may be is rather difficult to determine, but it must be over thirty years at the least."

The tolerable certainty that in a short time flowers and fruit of the Siam benzoin tree will be obtainable, and that the source of the drug can then be definitely set at rest, must be my excuse for bringing incomplete information before you. I need none for bringing the admirable specimens presented by Mr. Jamie under your notice.

The President, in moving a vote of thanks to Mr. Holmes, said the Conference ought also to thank Mr. Jamie for the specimen which had enabled Mr. Holmes to contribute his paper.

The President drew attention to a curious specimen of adulteration of beeswax, in which a coating of good wax had been apparently cast round a core of inferior quality.

The Conference then adjourned for luncheon.

* This evidently means that the seeds quickly germinate, as is the case with those of the Sumatra benzoin tree.

† If so, then, it supports my supposition that Palembang and Sumatra benzoin are produced by the same tree.

On resuming, the following two papers were read—

SESAME OIL: REPORT ON ITS SUITABILITY FOR PHARMACEUTICAL PURPOSES.

BY MICHAEL CONROY, F.C.S.

This is one of the subjects suggested by the Executive Committee of the Conference for investigation, and a reference is given in the "Blue List" to Flückiger and Hanbury's 'Pharmacographia,' wherein we find it stated that "good sesame oil might be employed without disadvantage for all purposes for which olive oil is used;" and a footnote in the same work further states that "for pharmaceutical uses, the larger proportion of olein and consequent lesser tendency to solidify should be remembered." These recommendations, coupled with the fact that it is one of the least alterable of the fixed oils, being much superior to olive in this respect, seemed to me to entitle the subject to further consideration, and the trouble of a few experiments with the view of solving the question.

The chief point to be observed in experimental work is to ascertain that the article operated upon is genuine; and with this in view the sesame oil used in these experiments was obtained from a reliable source, and it was further carefully examined by the usual tests for impurities. It was a pale, yellowish-coloured oil of sp. gr. ·921, possessing a bland, sweet, nut-like taste, with neutral reaction. Concentrated sulphuric acid converted it into a deep brownish-red jelly. The addition of 2 per cent. of a cooled mixture, in equal parts, of strong nitric and sulphuric acids caused it to acquire a deep green colour, rapidly changing into deep brown; and to other well-known tests it answered equally satisfactorily.

The principal use of olive oil in pharmacy is in the preparation of plasters, liniments and ointments, and to test the suitability of sesame oil for these, the following experiments were put in hand, and samples of the results are on the table.

1st. A small batch of lead plaster was prepared by the usual process, using sesame instead of olive oil. Combination took place as with olive oil, and occupied about the same length of time, but towards the end the plaster considerably darkened in colour, although steam was reduced and ample water present. The plaster, however, became fairly white by "pulling," but all attempts to make and retain it in the form of rolls were futile; and although the sample before you was made more than a month ago, it is still quite soft, and is not likely ever to set firmly. In respect to adhesiveness it is quite equal to that prepared with olive oil.

2nd. Liniment of ammonia was next tried, the result being a combination quite equal to that prepared with olive oil, and though a little thinner in consistency, it did not show any séparation after standing several days.

3rd. Liniment of lime. Specimens were made with sesame and olive oil, both with the same lime water, freshly prepared, and of full strength; the result being, with sesame oil, a liniment much thinner than the one prepared with olive oil, and which separated considerably on standing, while that made with olive oil kept well.

4th. With the official ointments into the composition of which olive oil enters, excepting ointment of nitrate of mercury, no difference was observed in the substitution of sesame oil. In the case of the nitrate of mercury ointment, however, the result was an unsightly orange-coloured preparation that in a few days became still more unsightly by working up in the jar and further darkening in colour.

It is, therefore, very evident that this oil cannot replace olive for the chief pharmaceutical uses, since plaster made with it will not set sufficiently to be portable, either in the form of rolls or when spread for use; neither can it satisfactorily be used for lime liniment, because of its tendency to separate. These defects are undoubtedly due to the large amount of olein contained in this oil, and consequently lesser proportion of the more solid glycerides; and it is very singular that these defects are what chiefly recommended the oil to the authors of the 'Pharmacographia,' namely, the "larger proportion of olein and consequent lesser tendency to solidify."

Where, however, no chemical combination takes place, and where simply a bland sweet oil, possessing good keeping properties is required as an ointment basis, perhaps no better could be chosen, and on this account I consider it much more suitable as a substitute for almond oil in the preparation of ointments. Samples of the principal ones contained in the British Pharmacopœia have been prepared, and are on the table, which, to my mind, are quite equal in every respect to those prepared with almond oil.

SESAME OIL: ITS SUITABILITY FOR PHARMACEUTICAL PURPOSES.

BY THOMAS MABEN, PHARMACEUTICAL CHEMIST.

The literature relating to sesame oil is very meagre, and in 'Pharmacographia' alone do we find anything like a satisfactory description of the article and its uses. The learned authors of that work state that the oil "might be employed without disadvantage for all the purposes for which olive oil is used," and it is with the view of indicating the reliability or otherwise of this opinion, that I have, acting on the suggestion contained in the "Blue List," undertaken the preparation of this report.

Sesame oil differs little in its physical characters from either olive or almond oils. It has not the tinge of green which all but the finest specimens of the former process, and is of a rather more decided shade of yellow than the latter, but generally speaking the difference in colour is not very marked. The odour of a fine specimen of sesame oil is very slight, while the taste is at first sweetish and bland with a peculiar after-flavour. Olive oil becomes grainy through the deposit of a crystalline fatty body at 5° C., but the olein does not solidify till about −5° C. Sesame oil congeals at −5° C., and almond oil is liquid till −20° C. is reached. The difference in the congealing points is doubtless due to the percentage of olein, of which almond oil "consists almost wholly" ('Pharmacographia'), sesame oil contains 76 per cent. (*Ibid.*), and olive oil, 72 per cent. (Braconnot). According to the best authorities, however, the percentage of olein varies according to circumstances; and, in like manner, different samples of the same oil differ in density, as is evident from the fact that hardly two authors agree in giving the same specific gravity for any one oil. The following table shows at a glance the relative specific gravities:—

	'Pharmacographia.'	A. H. Allen.	Other Authorities.	The Author.
Sesame oil .	·919 (23° C).	·923 to ·924	·932 . . .	·923
Almond oil .	·920 . . .	·916 to ·920	·917 to ·920	·919
Olive oil. . .	·916 (17·5°C.)	·914 to ·917	·910 to ·917	·918

From these figures it will be seen that olive oil is the least dense, while sesame oil is the heaviest. 'Pharmacographia' gives a very low specific gravity for sesame oil; but this may probably be accounted for by the difference in the temperatures at which the observations were taken, and by the fact that the oil made use of by Flückiger was extracted with ether, whereas the sesame oil of commerce is obtained by expression. Taking into consideration the physical properties generally of the three oils, it seems on *à priori* grounds quite probable that sesame oil would make a good substitute for either olive or almond oil, and I have in this investigation taken account of most of the galenical preparations in which these are employed.

Let me remark in passing that this similarity in appearance has led, according to some authorities, to the extensive use of sesame oil as an adulterant of almond oil, and probably also of olive oil. This sophistication may be detected in the case of almond oil by the application of a test mentioned in 'Pharmacographia.' "The oil shaken with (a mixture of equal weights of) sulphuric and nitric acids takes a fine green hue, as shown in 1852, by Behrens, who at the same time pointed out that no other oil exhibits this reaction." This coloration may be made use of in testing almond oil for sesame with perfect success, provided we bear in mind a fact not mentioned by Flückiger, viz.: that the green rapidly changes to a red brown. Pure olive oil takes on, with the same reagent, a shade of green, which might easily be mistaken for the green produced by a mixture of almond with 5 or 10 per cent. of sesame, were it not that the former is permanent, while the latter almost immediately passes into the red brown referred to. In the case of suspected olive oil, this reaction may be supplemented by Mr. Conroy's nitric acid test. Nitric acid when heated with seed oils till the action ceases produces a distinct red colour. When heated with olive oil, its only effect is (apparently) to change the oleic acid to elaidic acid which solidifies on cooling. This is a valuable test, giving indications even with very small percentages of foreign seed oil; but unfortunately different shades of colour are produced by different oils, and unless we are certain of the presence of a particular adulteration the colour is almost sure to mislead, though probably not to a very great extent. As this report has reference more to the use of sesame oil for pharmaceutical purposes than to its abuse as an adulterant, it is unnecessary to go further into the question of tests.

The two classes of preparations in which oils are chiefly used are the plasters and the ointments. In preparing these it must be remembered that there is a larger percentage of olein in sesame than in olive oil, and the proportions of the different ingredients must be regulated accordingly, otherwise the particular plaster or ointment will be too soft.

Plasters.—*Emplastrum plumbi* being the basis of nearly all the plasters, it may be taken as the type of this class of preparation, Lead plaster is essentially a soap and is prepared by heating together plumbic oxide and oil in the presence of water, the result being that the glycerine separates while the fatty acids combine with the metal to form the oleomargarate of lead. This plaster can be successfully prepared with sesame oil, the only modification in the process being the allowance of a larger quantity of oxide of lead, as just referred to. Prepared with olive oil, lead plaster is nearly white, very friable, and only slightly adhesive; prepared with sesame oil, it is darker in colour, much less friable, and much more adhesive. By itself the former cannot be used for adhesive plaster, the requisite "stickiness" being obtained by mixing with it a small quantity of resin and also a little soap. This forms *Emplastrum resinæ* and when spread on calico is the sticking-plaster of the shops. Though very adhesive, this is somewhat irritating on inflamed surfaces and liable, in homely phraseology, to "canker" a wound, and if sesame lead plaster were used alone, or with a smaller proportion of resin, it would in my opinion prove an excellent substitute.

Most of the plasters of which *Emp. plumbi* is the basis are, like itself, apt to become brittle when kept for a time. Belladonna and other plasters which are frequently kept ready spread crack disagreeably, and are not so adhesive as when recently prepared. The use of sesame oil for these also is an advantage.

Ointments.—Sesame oil is perfectly applicable for most of the British Pharmacopœia ointments, whether it takes the place of olive or almond oil. Spermaceti, resin and simple ointments are as elegant alike as regards colour, odour or consistency, as any prepared according to the Pharmacopœia, and so far as I have been able to judge quite as durable.

Some ointments are apt to change and become unfit for use, such as those of acetate of lead, iodide of cadmium, oxide and iodide of mercury, etc., and it is hardly probable that the use of sesame oil will arrest the usual course in their case, but after the lapse of several months, I find each of them quite sweet and good.

An ointment somewhat difficult to prepare and also to keep is *Ungt. hydrargyri nitratis*. Seed oils do not usually make a good preparation, owing to the presence of some peculiar reducing agent, which tends to decompose the mercury salts in the ointment. This decomposition is accomplished much more rapidly by some oils than by others; rape oil, for example, acting quickly, while sesame oil acts somewhat slowly. The action also goes on more energetically at a high than at a low temperature. In the case of rape oil, ointment prepared at 80° C. will keep good for a few days, perhaps even a month, but sooner or later it will inevitably go wrong. If, however, the temperature at time of preparation be raised to 100° C., decomposition takes place at once. On the other hand, ointment prepared with sesame oil at 100° C. keeps good for several months, but ultimately it becomes decomposed; while if the initial temperature be 150° C., decomposition will be immediate. I am at a loss to account for the reaction which takes place. From what we know of the action of nitric acid on seed oils, we would naturally expect the ointment to be red. It is, however, of a greenish hue, so that probably the nitric acid is made use of in another direction. Whatever be the cause of the reaction it is evident that sesame oil is quite unsuitable for the preparation of this particular ointment.

On a general review, we may conclude that in the case of plasters a superior preparation may in some instances be obtained by the use of sesame oil in place of olive oil; and that there is no reason why it might not be employed as a substitute for both olive and almond oil in the preparation of the B.P. ointments, with the single exception of *Ungt. hydrargyri nitratis*.

The President, in proposing a vote of thanks to Mr. Conroy and Mr. Maben, said those two gentlemen did not come to quite the same conclusion, but probably Mr. Conroy's objection would be met by Mr. Maben's suggestion to use more base where chemical reactions took place, as in certain of the liniments and plasters. They also differed slightly in the specific gravity of the oils, but no doubt different samples would differ in that respect.

A vote of thanks to the authors was passed.

Mr. Willmott said he gathered from what had been read that the sesame oil, although preferable in some instances, was not recommended as being generally superior to olive oil, whilst in some cases it was evidently inferior. He would simply suggest that in those cases where it had been considered equal or superior to olive oil some further time should elapse before any conclusion was arrived at.

Mr. Tanner said he had worked somewhat in the same direction, and could fully confirm what Mr. Conroy said as to sesame oil in the preparation of emplastrum plumbi. It made the plaster too soft if made in the proportions given in the Pharmacopœia. That objection seemed to have been met by Mr. Maben by using a larger proportion of lead oxide, but his experience was that there were other objections. The lead plaster made with sesame oil not only had an entirely different odour, but the odour was very disagreeable, and when the plaster was spread rancidity took place in a few days. So rapid was this action that he had known large quantities of this plaster when spread become so heated in twenty-four to forty-eight hours that it was considered dangerous to pack it. With reference to ung. hyd. nit., Mr. Conroy appeared to have an ointment which became first an orange and then an objectionable brown colour. He had found that it turned orange at first, and in a few days changed to red, and remained that colour for three or four months. Sesame oil, therefore, was not calculated to take the place of olive oil in the most valuable of pharmacopœial preparations. In linimentum ammoniæ it certainly seemed preferable.

Mr. Conroy said he had tried the experiment of adding a further amount of base, but still found the plaster soft, and he could not see how the use of a larger percentage of base would make the difference. With regard to the specific gravity, the one he had given was from the sample on the table, which he had every reason to believe was perfectly genuine. He did not think that a further length of time was necessary in testing this oil as compared with olive oil, because that also became rancid. The difference of odour mentioned by Mr. Tanner would not be much objection, because he did not think people cared about that in a plaster. The rancidity he mentioned was very likely due to the softer nature of the plaster. He was surprised at the colour obtained by Mr. Tanner, which was probably due to some other seed oil being present.

(*To be continued.*)

Parliamentary and Law Proceedings.

Alleged Poisoning by "Oil of Amber and Juniper."

At Crediton, on October 17, an inquest was held, before Mr. F. Burrow, District Coroner, relative to the death of Robert Ware, a labourer, who was found dead in bed on the previous Sunday, at Folley, near Crediton. The son of the deceased said that his father was suffering from lumbago, and on the previous Saturday he took some medicine he had from Mr. Tanner, just before going to bed. Witness saw him with the bottle, and his father told him that he took five drops. Just before getting into bed he said "Good night," and nothing more. Witness woke up in the middle of the night, and, seeing the lamp burning, said to his father, "Aren't you going to put out the light?" He did not speak, and witness got out and put out the light. He did not awake until 10 a.m. on Sunday morning, when he found his father was dead.

Mr. J. A. Edwards, surgeon, said he was called, and went to the residence of the deceased. He examined the body, and found no marks of violence, but dark patches of congested matter. On learning that the deceased had taken some medicine, he examined the bottle produced, labelled "Oil of amber and juniper." He was informed that the deceased had been taking it since the Monday previously, in doses of 4 or 5 drops. Witness never heard of the internal application of amber, but knew it was used sometimes externally for paralysis or rheumatism. On referring to an old work he found it recorded as being used internally as a stimulant; it was generally used as an embrocation. Witness was informed by the son of the deceased that he took on Tuesday night 19 or 20 drops. He (witness) thought the cause of death was asphyxia, produced by overdoses.

Police Constable Burd said that Mr. Tanner, the chemist, told him that the deceased had only twopennyworth, and his instructions were that he was to take only 4 or 5 drops for a dose.

The Coroner said it was most extraordinary that the bottle was not labelled "Poison," and that no instructions were on the label.

The Jury returned a verdict that death ensued through misadventure, from the deceased having taken an overdose of oil of amber and oil of juniper.

The Coroner thought that the bottle should have been labelled.

Several of the Jury were of the same opinion, and considered that Mr. Tanner should have been more careful in sending out medicine, as well as in giving proper instructions as to how it was to be taken.—*Exeter and Plymouth Gazette.*

Poisoning by Sulphate of Copper.

An inquest was held on October 26, at the Leeds Town Hall, before Mr. J. C. Malcolm, the Borough Coroner, on the body of Sarah Wetherell (52), wife of a labourer.

The husband said he left home on Saturday night about eight o'clock, and returned at eleven. When he got into the house he found his wife lying on the floor apparently asleep. Thinking she was under the influence of drink, he merely lifted her into bed and went to bed himself. When he awoke on Sunday morning his wife told him that in the dark she had drunk a cupful of a solution of sulphate of copper, or blue vitriol, in mistake for water. Mr. Clayton, surgeon, was called in, but the woman gradually grew worse, and died on Thursday.

A verdict of "Died by misadventure" was returned.—*Leeds Mercury.*

Obituary.

BENJAMIN HUMPAGE.

Another "Founder" of the Pharmaceutical Society, and one whose face was familiar to many of its members, has passed away in Mr. Benjamin Humpage, of Turnham Green. The deceased gentleman was the fourth son of the late Mr. Edward Humpage, Surgeon, of Stroud, Gloucestershire, to whom he was apprenticed and served his time. He then went as assistant to a chemist in the City of Gloucester, and subsequently came to London, where he became assistant in the shop till lately owned by Mr. Pedler, near Temple Bar.

Mr. Humpage afterwards proceeded to Bristol and opened, in 1830, a shop for himself in North Street, which subsequently became the property of the late Mr. W. W. Stoddart. Failing health compelled him to leave Bristol, and he returned to London, where he became well known as a medical transfer agent and valuer, with offices in Chancery Lane, while at the same time he carried on business as a pharmacist in Judd Street, Brunswick Square. The demand for his services as medical agent increased as his uprightness of character and keenness of perception were recognized; but in 1867 his health again became affected and he then removed to Turnham Green (or, as it is now called, High Road, Chiswick), where he continued in business up to the time of his death at the ripe age of 76 years.

The above bare facts do not convey any idea of his useful, well-spent life. He lived and acted up to the maxim that "whatever is worth doing at all is worth doing well;" and his bright and happy-looking face and genial greeting were household words among his friends.

Mr. Humpage was one of the earliest to join the Pharmaceutical Society and on two occasions was elected an auditor. He always manifested a strong interest in the proceedings of the Society, and many who had not the privilege of personal friendship with him will retain pleasant memories of his appearances at the annual meetings, where his good natured presence and sensible though somewhat emphatic oratory always tended to soothe any acerbities that might have arisen in discussion.

Notice has also been received of the death of the following:—

On the 2nd of October, Mr. George Gilbert, Chemist and Druggist, Waterloo Ville. Aged 68 years.

On the 12th of October, Mr. John Bray, Pharmaceutical Chemist, High Street, Mile Town, Sheerness. Aged 43 years. Mr. Bray had been a Member of the Pharmaceutical Society since 1863.

Liquid Extract of Cinchona.

Sir,—I observe that Mr. Heathfield, in your issue of October 20, claims to have a knowledge of the method originally adopted by Mr. Richard Battley in the production of his Liquor Cinchonæ. After describing the method as consisting in the treatment of bark with cold water, not by mere "digestion and evaporation," but by a "process of manipulation and elimination," he says that "no spirit was added at the completion." He claims for Mr. Battley that he "attained the object in view, viz., that of separating and securing nearly the whole of the medicinal properties of the bark," and says "I have little doubt that if the successor of the late Richard Battley continues, as is presumable, the same process, the preparation will long hold its own against all comers." Not content, however, with thus commending this particular preparation, which is well known in commerce as a proprietary medicine, he does not hesitate, in terms which, taken alone, are somewhat equivocal, but considered with the context are unmistakable, to condemn the corresponding preparation of the British Pharmacopœia. He says, "in the year 1830 I was working with Mr. Battley in his laboratory, and I can certify that the extractum cinchonæ liquidum of the British Pharmacopœia has no more relation to the liquor cinchonæ introduced by Richard Battley, as then and there prepared, than has the extractum opii liquidum to the liquor opii sedativus of the same discoverer." He goes even further and says that the framers of the Pharmacopœia have much aided in bringing the pharmacy of the cinchona bark into a muddle, and suggests that this has arisen from their not having gone to the right source for their information. "In justice to another," he very properly observes, "it is not for me to recapitulate the operations" of the process, but "did they apply, before completing their work, to those who were acquainted with the matter in all its details?"

An answer to this question will be found, not only in a published statement by Dr. Farre, who for many years occupied a prominent official position in the London College of Physicians, but in a communication from Mr. Richard Battley, which appears in the tenth volume of the *Pharmaceutical Journal*, page 129. Dr. Farre, in his 'Abridgment of Pereira's Materia Medica,' distinctly says that the formula for liquid extract of cinchona was furnished by Mr. Battley himself to the London College. And Mr. Battley gives, for the benefit of all comers, a detailed description of his process. He says "I introduced in 1818 the form of liquor, or inspissated cold infusion, evaporating the cold infusion at a temperature not exceeding 160°, to the specific gravity of 1200, and afterwards, to preserve this liquid extract from decomposition, adding to it as much rectified spirit as will reduce the specific gravity to 1100." This is precisely the process given in the Pharmacopœia, and unless we credit Mr. Heathfield in preference to Mr. Battley, it is the process which the latter adopted.

The framers of the Pharmacopœia had, therefore, no occasion to apply to Mr. Battley's successor, or to his former assistant, for information which, as the former would naturally, and the latter very properly, say "in justice (to myself or) to another, it is not for me to recapitulate the operations."

This is one of the difficulties the framers of the Pharmacopœia have to contend with, that those who are most able to render assistance may have interests in an opposite direction. I should be sorry to suppose that such interests would be allowed to interfere with the exercise of a duty which devolves upon pharmacists throughout the country, to assist in the production of a good Pharmacopœia.

The liquid extract of cinchona of the British Pharmacopœia has been much criticized. I have no doubt it admits of improvement. If so, in what direction and how? This is one of many questions which pharmacists may assist in answering, and in doing so they would not only tend to justify their claim to the recognition and support they receive from the Legislature and the public, but at the same time they would be furnishing matter for professional and scientific discussion and publication, from which they individually, and all, would benefit.

T. Redwood.

Sir,—In the *Pharmaceutical Journal* for September, 1850, there is a paper by Mr. Battley detailing his method for making his liquors.

He says:—"I have been led to adopt as a rule for the maceration of most substances, twice their weight of cold distilled water, adding for each subsequent maceration as much additional distilled water as the amount of infusion drained off or expressed."

He says further on:—"I introduced in 1818 the form of liquor, or inspissated cold infusion, evaporating the cold infusion at a temperature not exceeding 160° to the specific gravity of 1200, and afterwards, to preserve this liquid extract from decomposition, adding to it as much rectified spirit as will reduce the specific gravity to 1100."

I trust this will disperse the mists hanging round the subject.

18, *Borough High Street, S.E.* C. D. Parry.

Sir,—I would like to draw attention to what appears to me to be an error on the label of a preparation which has recently elicited considerable attention and discussion, namely, Battley's Liq. Cinchonæ. It occurs in the first sentence, which reads thus:—"One fluid drachm is equivalent to 1 ounce of the finest bark or 12 ounces of the decoction." Since 1 ounce of bark is sufficient to make 16 of decoction, and 1 drachm of Battley's is equal to 1 ounce of bark, 1 fluid drachm ought to be equivalent to 16 (and not 12 ounces as stated) ounces of decoction. But for two reasons it should be equal to more than 16 ounces. The first is that in preparing the B.P. decoction, much of the alkaloids is left in the bark. The second is because much of the alkaloids is deposited upon the decoction cooling, and therefore 16 ounces of this preparation is not equivalent to 1 ounce of the bark. I think I have now made it clear that 1 drachm of Battley's preparation, if it is really equal to 1 ounce of bark, should make more than 16 ounces of decoction.

I see by the Journal of October 20, that Mr. Heathfield assisted the late Mr. Battley in his experiments. Perhaps that gentleman will show that Battley's label is right, or that I am wrong. Being familiar with the preparation he would be able to give the necessary explanation.

One more question and I have finished. In diluting Liq. Cinchonæ, Battley directs soft and distilled water. In what way does it differ from hard and distilled or simply distilled water?

D. Cinchon.

Hymenodictyon Excelsum.

Sir,—It would doubtless be very inconvenient if the discussions at the Pharmaceutical Conference were to be continued in your Journal; but if there is not too much danger of that, I should like to add a sentence to what was said with reference to Mr. Naylor's paper on the principles of *Hymenodictyon excelsum*.

It is quite conceivable that the formulæ given for the alkaloid and neutral principle are correct empirically, in the sense that they are the simplest expression of the composition of the substances, as CN is of cyanogen. We may wait a very long time before we know the constitutions of hymenodictionine, and what I object to is just this, that a formula should be given even provisionally, which contradicts one of the best established laws of chemistry. The difficulty might be overcome by doubling the formulæ, but I would suggest as a preferable process, that Mr. Naylor should add an atom of hydrogen to each of his compounds, which would satisfy me, and agree just about as well with his analyses.

I have no wish to say anything hypercritical regarding a research, the value of which I fully appreciate.

93, *Abbey Hill, Edinburgh.* D. B. Dott.

Ungt. Hydrargyri Nitratis.

Sir,—Pharmacists owe a debt of gratitude to Mr. Willmott for his most valuable contribution to the literature of the ointment bases, and I regret that I was unable to attend the Conference so that I might have expressed my thanks along with others, and at the same time replied to his remarks on my paper on "Ungt. Hydrargyri Nitratis." With your permission I desire to refer briefly to these remarks now, and in doing so shall follow the order adopted by Mr. Willmott in his criticism.

Referring to what Mr. Willmott calls my "theory," I think that if he re-reads my paper he will find that anything in the paragraph on deterioration of the nature of a theory is based on data given in the previous part of the paper; the conclusion I come to being that should the ointment deteriorate "within a few months," even though every care had been taken in its preparation and preservation, "the presumption is that the oil was not pure." The context clearly shows that this is no broad theory, and not even applicable to all cases of early deterioration, but that it is limited to certain conditions. I do not gather from Mr. Willmott's paper that any experiments which he may have made lead to a contrary opinion.

I am quite at one with Mr. Willmott in the opinion that olive oil will under certain circumstances reduce mercurous nitrate, and there is no necessity to reheat citrine ointment* to prove this, but these circumstances are not present in the preparation of ung. hydr. nit. So long as nitric acid is in the slightest excess olive oil will not reduce the mercury salts, whereas the action of seed oils goes on whether the acid is present in excess or not.

Mr. Willmott states that olive oil ointments do not deteriorate for the reason that "a larger proportion of the acid is retained in its normal condition." In my opinion this is certainly not the sole reason. The proportion of acid undoubtedly exerts some influence as between one pure olive oil ointment and another, but as between an olive oil ointment and a seed oil ointment the difference is due not so much to the acid as to some active principle in the seed oil. A simple experiment will prove this. Let an olive oil ointment be prepared at a temperature above the boiling point of nitric acid, when, surely all the acid in excess will be evaporated, and let a seed oil (or a 10 per cent. seed oil) ointment be prepared under the boiling point of the acid and note the result.

With reference to the nitric acid, I quite agree with Mr. Willmott that all change would be prevented by increasing the quantity, provided the added acid be not driven off by increasing the temperature at preparation; but I fear the ointment would differ from the B.P. article in its therapeutic value. There is, however, no necessity to increase the quantity of acid ordered by the B.P.; if the oil is pure, the ointment will keep unchanged for a very long time, and if the oil is impure increase of acid will not prevent reduction taking place.

Mr. Willmott, referring to lard, states that its reducing power is even lower than that of oil, for with lard alone "there is no subsequent deterioration in point of colour." But according to his own showing citrine ointment, especially when recently prepared, cannot be mixed with lard "without quickly acquiring a leaden hue, owing to the reduction of the mercury." If this is so, some explanation of the apparent contradiction is evidently necessary. But it is not always so, as one ointment may be mixed with lard and yet preserve its colour, while another cannot be so diluted. The difference is simply this, that the former has been prepared at a lower temperature, the mercury exists in combination with the fats, and there is also an excess of acid, while the latter has been prepared at a higher temperature, and the mercury exists as nitrate, with very little, if any, excess of acid. The remedy for this reduction may, therefore, be found in the addition of a few drops of nitric acid to the ointment before mixing in the lard.

The meaning of the expression "prepared at" say 212° F., is simply this, that the acid solution is to be added when the fats are at that temperature, the initial temperature being the most convenient as a guide and really the only one at all practical. I am well aware that the temperature rises as the action proceeds, but I was not prepared for the great rise noted by Mr. Willmott. If this rise takes place in every instance, it would be utterly impossible by starting at 180° F. to prepare an ointment entirely soluble in ether; yet we know that Mr. Schacht did prepare such an ointment, while I myself have done so repeatedly. That it does not always take place I proved no later than yesterday. Operating with 2 pounds of ointment, I began to add the acid solution when the fats were at 180° F. The temperature rapidly rose to 220° F., but fell before the process was half over to 208° F., at which point it was stationary even when the frothing was at its highest. With a second quantity of 2 pounds I begun at 212° F., the temperature rose to 240° F., and then gradually fell to 218° F., at which it remained till the action had ceased. With smaller quantities (2 ounces or thereby) such as those I worked with when preparing my paper the temperature does not run up so high in either case.

Mr. Willmott has failed to notice that the effect of different temperatures of preparation is to yield ointments of different composition. Probably this was outside the scope of his paper, but the composition is essentially related to the temperature and they should be considered together. It is, however, unnecessary for me to enter into this point, as I have already indicated in my paper the opinions I have formed regarding it; but I simply mention it to show that there really is some ground for asking that a definite temperature should be stated in the Pharmacopœia, as it is quite possible that abundant frothing may take place and the temperature be still a long way under 250° F. If, however, Mr. Willmott believes that this temperature is reached when the "frothing up of the mixture" takes place, he can surely have no objections to the ultimate, *i.e.* the highest, temperature being fixed at not less than 250° F., with which I for one would be quite satisfied, as then we could rely on always producing a uniform ointment and one which would really contain nitrate of mercury.

Hawick. THOS. MABEN.

* Mr. Willmott states that I heated a specimen of ointment to 300° F. This is not so. The expression "this pure ointment retains its colour though heated to over 300° F.," refers to the original heat of preparation, and not to reheating, the latter being an experiment I never dreamt of. The mercury in citrine ointment would be reduced long before 300° F. was reached if reheating were attempted.

Inquirer.—It would depend upon whether the person had any claim to use the designations referred to, and also the purpose for which he sought to use them.

J. C. Husband.—The tree is a poplar, and the "weedy stuff" which stopped up the drain consists of fine rootlets from it that have penetrated through the clay at the joints in search of moisture.

F. J. D.—We cannot give you any information, as the date of the publication of the next edition of the British Pharmacopœia belongs to the "future of pharmacy."

T. P. J.—We believe that unless a person had practised veterinary surgery continuously for five years before the passing of the Act it would be necessary for him in order to become entitled to registration to pass the statutory examinations, particulars concerning which may be obtained from the Registrar, 10, Red Lion Square, W.C.

A. L. Smith.—A solution of sp. gr. 1·750 would contain 20·4 per cent. of P_2O_5.

M. P. S.—We do not know of a published formula for Locock's lotion for the complexion.

F. J. P. S.—The flocculent precipitate in the liq. sodæ arsenitis was most probably one of the fungi commonly met with in arsenical solutions.

E. E. M.—The method of preparing dialysed iron will be found in back numbers of this Journal.

W. J. Barnes.—(1) Magnesiæ sulphas was doubtless intended in this prescription, which would give ʒj for a dose. (2) This requires the addition of ℥j of vaseline to combine the ingredients in an ointment.

Puzzled Chemist.—The answer to your question might be affected by the circumstances of the case: the actual composition of the pills and the persons to whom they are sold. Certainly it would not be affected by the fact that the label is small or otherwise occupied. Concerning the general question you are recommended to read the "case" submitted to the Privy Council for its opinion in 1869, and the reply thereto (*Pharm. Journ.*, [2], x., 566).

E. C. S.—Any good work on arithmetic.

E. Elsey.—The Prussian Pharmacopœia is no longer official, having given place to the German Pharmacopœia; but neither of these includes "Pulv. Sennæ Co." Probably "Pulv. Liquritiæ Co." is intended, which contains sulphur.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Mason, Ince, Bolton, Siebold, Thompson, Associate.

THE CLASSIFICATION AND PROPERTIES OF RED RESINS KNOWN UNDER THE NAME OF DRAGON'S BLOOD.*

BY J. J. DOBBIE, M.A., D.SC.,

Assistant to the Professor of Chemistry, Glasgow University,

AND G. G. HENDERSON, B.SC.

Having recently, at the request of Professor Balfour, of Glasgow University, undertaken the investigation of a red resin brought by him from the island of Socotra, we were led for purposes of comparison to examine a large number of similar resins from various sources. One result of this investigation was to prove that several substances of distinct chemical properties have hitherto passed under the same name. Besides the red resins derived from *Pterocarpus Draco* and *Croton Draco* the existence of three different kinds of dragon's blood has long been recognized; one from the East Indies (*Calamus Draco*), one from the island of Socotra, and one from the Canary Islands (*Dracœna Draco*). While the first of these has been fully described, no essential characters are given by any of the authorities whereby the others can be distinguished from it or from one another.

Flückiger and Hanbury ('Pharmacographia') have evidently taken great care to obtain authentic specimens of the *Calamus* resin on which to determine its characters. The only point in which the specimens of resin undoubtedly from *Calamus* examined by us appear to differ from those examined by these authorities is the solubility in ether. According to Flückiger and Hanbury the *Calamus* resin is sparingly soluble in ether, whereas we found it freely soluble. But there is a marked discrepancy on this point in all the published accounts of the resin. Thus according to Wiesner it is difficultly soluble, Hager ('Handbuch der pharmaceutischen Praxis') partially soluble; Herberger, soluble, but not so easily as in alcohol; Hirschsohn (*Russ. Zeit. Pharm.*, xvi., 1, 33, 65, 97), completely soluble. This and numerous other discrepancies render it probable that different experimenters have not always worked with the same substance. And when we came to compare the published accounts of dragon's blood with the substances actually sold under that name or exhibited as such in our museums, we found still greater difficulty in reconciling the descriptions with the observed properties.

We resolved, therefore, to collect as many varieties as possible of resins passing under the name of dragon's blood and compare them closely with one another. Through the kindness of Professor Balfour, we obtained from Mr. Holmes of the Pharmaceutical Society's Museum, from the Kew collection, and from the Warrington collection a large number of specimens, of which it may be well before proceeding further to give a list together with a note of their appearance and a copy of the label attached to each.

From the Kew Collection.

1. "Dragon's blood. India Museum. No locality." In lumps; colour of powder, dingy brick-red.

2. "Dragon's blood. *Calamus Draco*, Bombay. India Museum." In lumps; colour of powder, dingy brick-red. Contains about 9·5 per cent. of insoluble matter.

3. "Heraduccan, Singapore. India Museum." In lumps; colour of powder, dingy brick-red.

4. "Dragon's blood, Penang. India Museum." In small fragments; colour of powder, dingy brick-red. Contains about 21 per cent. of insoluble matter.

5. "Dragon's blood, Punjab. India Museum." In lumps; colour of powder, dingy brick-red. Contains about 20 per cent. of insoluble matter.

6. "Resin called dragon's blood. Menier and Co." In lumps; colour of powder, light orange-brown (colour of limonite).

7. "Dragon's blood. *Calamus Draco*, Singapore." In lumps; colour of powder, brick-red (colour of hæmatite). Contains about 12 per cent. of insoluble matter.

8. "Dragon's blood, Sumatra. Exhibition, 1851." In lumps; colour of powder, brick-red (colour of hæmatite).

9. "Dragon's blood. Different qualities obtained from fruits of *Calamus sp.*, Djambi and Siak, Sumatra." In lumps; colour of powder, dingy brick-red.

From the Pharmaceutical Society's Museum.

10. "Portion of agglomerated sticks. Dutch East Indies. Paris Exhibition, 1878." In sticks; colour of powder, light carmine-red.

11. "Dragon's blood. India Museum. Labelled Sumatra." In lumps; colour of powder, brick-red.

12. "India Museum. No locality given. Probably *Calamus*." In lumps; colour of powder, dingy brick-red.

13. "Paris Exhibition, 1878. From Pontianak. Djernang Sanpit. Catalogue, No. 547. Probably *Calamus*." In sticks; colour of powder, carmine-red.

14. "Stick in palm-leaf from Pontianak, Dutch East Indies. Indian Department, Paris Exhibition, 1878. Catalogue, No. 547. Probably from *Calamus*." In sticks; colour of powder, carmine-red. Contains about 4 per cent. of insoluble matter.

24. "Dragon's blood from *Dracœna Draco*. Gerarde Jose de Nabrega, Funchal, Madeira." In small fragments; colour of powder, cinnabar-red. Contains about 6 per cent. of insoluble matter.

From the Warrington Collection.

15. "Lump dragon's blood." Colour of powder, brick-red.

16. "Dragon's blood, said to be *Calamus*." In lumps; colour of powder, brick-red.

17. "Stick dragon's blood, *Calamus*." Colour of powder, dull pink.

18. "Finer stick dragon's blood." Colour of powder, scarlet.

19. "Lump dragon's blood." Colour of powder, scarlet.

20. "Lump dragon's blood in palm leaf." Colour of powder, scarlet.

21. "*Croton erythrina*. Dragon's blood resin, Brazil. Dr. T. Peckolt, Rio." In small lumps; colour of powder, brick-red.

22. "Smaller stick of dragon's blood in palm leaf." Colour of powder, brick-red.

23. "Larger stick of dragon's blood in palm leaf." Colour of powder, brick-red.

* Read at an Evening Meeting of the Pharmaceutical Society of Great Britain, November 7, 1883.

From Professor Balfour.

25. "Dragon's blood from *Dracæna Cinnabari*, Balf. fil., Socotra." In drops; colour of powder, cinnabar-red. Contains about 3·4 per cent. of insoluble matter.

On examining this list it will at once be evident that the resins known as dragon's blood differ widely from one another, not only in their degree of purity, but also in their appearance; and it will be seen from what follows that specimens labelled as having come from the same locality must, in reality, in some cases, have been derived from very different sources. It is even questionable if the term dragon's blood is properly applied to some of them, unless that term is to include all commercial varieties of red resins.

We first classified the specimens roughly according to their more prominent characters. They are all, with the exception of No. 21, which is derived from *Croton erythrina*, and is not usually described as a dragon's blood, freely soluble in alcohol, ether, oil of cloves and glacial acetic acid; the residue left in each case, which, as already mentioned, is very variable in amount, usually consists of vegetable tissue, sand, etc. There is, however, a marked difference as regards the solubility of the resins in other reagents, especially in chloroform, carbon bisulphide and benzene, and all the specimens admit readily of classification according to their behaviour when treated with these solvents. All the resins we have examined may be arranged in the four following groups. First, those which are entirely soluble in chloroform, carbon bisulphide and benzene; secondly, those which are soluble in chloroform, but insoluble in carbon bisulphide and benzene; thirdly, those which are soluble in chloroform and benzene, and *partially* soluble in carbon bisulphide; and fourthly, those which are insoluble in all three reagents. In the following table the specimens are arranged in the classes to which they belong:—

CLASS I. Resins soluble in chloroform, carbon bisulphide and benzene.*	CLASS II. Resins soluble in chloroform, insoluble in carbon bisulphide and benzene.	CLASS III. Resins soluble in chloroform and benzene, *partially* soluble in carbon bisulphide.	CLASS IV. Resins insoluble in chloroform, carbon bisulphide and benzene.
6. —	10. Dutch East Indies.	3. "Heraduccan," Singapore.	1. —
7. *Calamus Draco*, Singapore.	14. Pontianak, probably from *Calamus*.	4. Penang.	2. *Calamus Draco*, Bombay.
8. Sumatra.	17. *Calamus Draco*.	9. Fruits of *Calamus*, Sumatra.	5. Punjab.
11. Sumatra.	22. —	18. —	12. Probably *Calamus*.
	23. —	19. —	15. —
	13. Djernang Sanpit, Pontianak.	20. —	16. Said to be *Calamus*.
			24. *Dracæna Draco*, Madeira.
			25. *Dracæna Cinnabari*, Socotra.

In this list we have repeated the source or locality assigned to each resin, and it will be seen at a glance, especially at the fourth class, that a widely different source has been assigned to resins really identical with one another, and probably all derived from the same species, at all events from the same genus, while on the other hand the "calamus" resin occurs in all four classes. It was pointed out to us by Mr. Holmes, with regard to the resins exported from Bombay and said to be from *Calamus*, that they were probably imported into India, in the first instance from the east coast of Africa, and may have been derived from *Dracæna sp.* growing on the African coast or in the island of Socotra. The soundness of the classification which we have given and which is based primarily on solubility was entirely confirmed by an examination of the physical properties of the resins and of their behaviour towards various reagents. It would be useless to enter into details with regard to each resin in the list. We shall, therefore, confine ourselves to a general account of their properties and reactions, premising that the members of each group, as far as examined, show the closest agreement with one another. When carefully purified by solution in ether and reduced to powder, the resins of Classes I. and III. have a deep brick-red colour, those of Class II. a pink, and those of Class IV. a vermilion colour. In alcoholic solution a corresponding difference of colour is observable, Classes I. and III., being orange, Class II. pink-red (raspberry colour) and Class IV. blood-red. When heated, the resins of Classes I. and III. melt at about 80° C., and when the temperature is raised to their decomposing point give off highly irritating, red-coloured fumes; those of Class II. melt about 100° C. and give off aromatic non-irritating fumes, and those of Class IV. at about 60° C. and give off aromatic irritating fumes. All the resins dissolve to a slight extent in boiling water, those of Class IV. being rather more soluble than the others. The aqueous as well as the alcoholic solutions have an acid reaction. The behaviour of the resins of the different classes when treated with various reagents may be most easily exhibited in tabular form. The table is printed at the top of the next page.

The behaviour of the alcoholic solutions under treatment with various reagents, especially acetate of lead, is also characteristic. The resins of Classes I. and III give with acetate of lead a brownish-red precipitate, those of Class II. a lilac coloured precipitate, and those of Class IV. a mauve coloured precipitate, the precipitates being in all cases soluble in excess of alcohol, but insoluble in boiling water, ether, carbon bisulphide, benzene and chloroform. Hydrochloric acid dissolves all the resins to a slight extent, those of Class II. being somewhat more freely soluble than the others; ammonia reprecipitates the resins from the hydrochloric acid solution. The results of the analyses contained in the following table further confirm the classification which we have adopted. It is always a matter of difficulty to obtain resinous substances in a state of sufficient purity to admit of reliable analyses being made, but the results we obtained agree exceedingly well with one another and enable us to place confidence in the formulæ which we have assigned to the resins. Before burning the resins we purified them by dissolving repeatedly in ether

Table of Reactions.

	Class I.	Class II.	Class III.	Class IV.
Caustic soda . .	Almost insoluble in strong cold soda. Soluble in boiling soda to an orange-red fluid.	Readily soluble in strong, cold soda with beautiful purple colour, which changes to orange-yellow on dilution or boiling.	Almost insoluble in strong cold soda. Soluble in boiling soda to an orange-red fluid.	Soluble in cold soda with an orange-red colour.
Ammonia (·880) .	Slightly soluble in cold ammonia. Gives a reddish-yellow solution when heated, a portion being apparently insoluble.	Readily soluble in cold ammonia with a splendid purple colour.	Rather more soluble in cold ammonia than the resins of Class I.	Readily soluble in cold ammonia with a blood-red colour.
Lime Water . .	Insoluble in cold, and almost insoluble in boiling lime-water.	Soluble in cold lime-water with a purple-pink colour, which changes to orange-red on boiling.	Insoluble in cold, and soluble with difficulty in boiling lime-water.	Soluble in cold lime-water with a blood-red colour, which changes slightly on boiling.
Sodium Carbonate	Insoluble in cold sodium carbonate. Soluble in boiling sodium carbonate to an orange-red fluid, smelling like rhubarb.	Soluble in cold sodium carbonate with a mauve-pink colour, which changes to orange-red on boiling.	Insoluble in cold sodium carbonate. Soluble in boiling sodium carbonate to an orange-red fluid, smelling like rhubarb.	Soluble in cold sodium carbonate with a blood-red colour, which changes to orange-red on boiling.

Note.—When treated with caustic soda the resins effervesce, and a peculiar odour, like that of rhubarb is given off. Ammonia forms a clear mixture with alcoholic solutions of all the different classes.

and then precipitating from alcoholic solution with water, having previously heated the resins for several days at a temperature sufficient to expel volatile matter, of which traces are present in all of them.

Table of Combustions.

	Class I.		Class II.		Class III.		Class IV.	
	1	2	1	2	1	2	1	2
C	71·03	70·79	68·18	68·22	70·32	69·41	72·80	72·41
H	6·45	6·42	6·00	6·04	6·01	6·04	6·03	6·07
O	21·52	22·72	24·82	25·74	23·67	24·55	21·17	21·52
	100·00	100·00	100·00	100·00	100·00	100·00	100·00	100·00
					3	4	3	
				C	73·10	71·89	72·16	
				H	5·81	6·56	6·11	
				O	21·09	21·55	21·73	
					100·00	100·00	100·00	

From these numbers we calculated for the resins of Classes I. and IV. the formula $C_{18}H_{18}O_4$. A substance having this composition would have a combining weight of 298 and contain 72·48 per cent. of carbon, 6·04 per cent. of hydrogen, and 21·48 per cent of oxygen—numbers which agree very closely with those determined by actual experiment, especially with the resins of Class IV. In the case of the resins of this class the formula calculated from the results of combustion was confirmed by analysis of the lead salt, three determinations of which gave respectively the numbers 25·33, 25·27 and 25·17 as the percentage of lead. On the assumption that this resin is a monobasic acid the composition of the lead salt would be $(C_{18}H_{17}O\ )_2Pb$, containing 25·84 per cent. of lead, a number which agrees very closely with that obtained by experiment. The resins of Class II. seem to have a somewhat different composition. If we assume their formula to be $C_{17}H_{18}O_5$ and calculate back to the percentage composition, we obtain the numbers C. 67·54, H. 5·96 and O. 26·50. We found it impossible to obtain consistent results in the case of the resins of Class III., the reason of which we shall presently explain.

Numerous analyses of dragon's blood are given by Johnstone (*Phil. Trans.*, 1859, 134; 1340, 384), and others. It is uncertain which variety of red resin Johnstone worked with, but his analyses agree tolerably closely with those of the resins of our first and fourth classes, to which the varieties most frequently met with seem to belong.

The resins of our third class are undoubtedly mixtures of two distinct resins which differ widely from one another in appearance and properties, although we were unable to separate the two portions sufficiently well to admit of reliable analyses being made. Johnstone found in one kind of dragon's blood which he examined two red resins, to one of which he assigned the formula $C_{20}H_{20}O_4$, and to the other the formula $C_{20}H_{21}O_4$.

Our results may be summed up as follows. There are at least four distinct kinds of red resin presently sold as dragon's blood, or labelled in collections under that name. One variety is brick-red in colour, melts at about 80° C., gives off red-coloured highly irritating fumes when decomposed by heat, dissolves readily with an orange-red colour in alcohol, ether, chloroform, carbon bisulphide and benzene, is insoluble or only slightly soluble in cold caustic soda, ammonia, lime water and sodium carbonate, and dissolves with difficulty when boiled in these reagents. Its alcoholic solution has an acid reaction and gives a brown-red coloured precipitate when mixed with a solution of lead acetate. Its composition may be represented by the formula $C_{18}H_{18}O_4$. This is undoubtedly the resin of *Calamus Draco*, some of the specimens which were examined having their origin well authenticated.

A second variety is of a beautiful carmine-red colour, melts about 100° C., gives off non-irritating fumes when decomposed by heat, dissolves freely with a pink colour in alcohol, ether and chloroform, but is insoluble in carbon bisulphide and benzene, dissolves readily in cold caustic soda, ammonia and sodium carbonate, and much more readily than the foregoing in lime water. Its alcoholic solution has an acid reaction and gives a lilac-coloured precipitate with lead acetate. Its composition may be represented by the formula $C_{17}H_{19}O_5$. The source of this resin is quite uncertain. We have no means of determining whether it is identical with any hitherto described variety of red resin. The specimens examined are marked as having come from the Dutch East Indies, but beyond this we know nothing of their origin.

A third variety is of a vermilion colour, melts about 80° C., gives off aromatic irritating fumes when decomposed by heat, dissolves with a blood-red colour in alcohol and ether, but is insoluble in chloroform, carbon bisulphide and benzene, dissolves readily in cold caustic soda, ammonia, lime water and sodium carbonate. Its alcoholic solution has an acid reaction and gives with lead acetate a mauve-coloured precipitate. Its composition may be represented by the formula $C_{18}H_{18}O_4$. This is the resin from species of *Dracæna*. One of the specimens examined is from *Dracæna Cinnabari*, Socotra, and as it was gathered by Professor Balfour there can be no doubt as to its origin. Another specimen is from *Dracæna Draco*, and its origin is also well authenticated. The other specimens examined are marked some of them *Calamus*, but there can be little doubt that this is a mistake, and that all the resins having the properties just enumerated are derived from species of *Dracæna*. It seems certain then that the resin derived from *Dracæna sp.* is totally different in property from that derived from *Calamus sp.*

The fourth variety is a mixture, in varying proportions, of a reddish-brown coloured resin, freely soluble in carbon bisulphide, and a light brick-red coloured resin, nearly insoluble in carbon bisulphide. The two portions also differ considerably as regards their solubility in ether, benzene, and other reagents, the dark portion being in all cases the less soluble of the two. Since, however, it dissolves to a slight extent in all reagents we found it impossible to effect a complete separation of the two portions. The portion freely soluble in carbon bisulphide is probably identical with the resins of our first class, while the other portion seems to be a distinct resin.

Much discussion has taken place with regard to the presence of a volatile acid in dragon's blood. It seems certain that none of the varieties of this resin contain benzoic acid; at all events we failed to obtain an extract from any of them with petroleum ether, in which benzoic acid is freely soluble. We tested for cinnamic acid by sublimation, and found it present in the resins of the first and third classes, but not in those of the second and fourth classes. To ascertain the delicacy of this method we made a preliminary experiment with artificial mixtures containing 1 per cent. of cinnamic acid, and found that the acid could be separated out by sublimation from very small quantities of such a mixture. Probably the error as to the presence of benzoic acid arose through confounding it with cinnamic acid, or possibly from working with a resin in which benzoic acid had been formed by partial oxidation.

Several valuable investigations upon the decomposition products yielded by dragon's blood, when subjected to destructive distillation and to the action of various oxidizing agents, have been conducted by Hlasiwetz and Barth, and others. Though probably the different kinds of resin will be found to yield nearly the same products, it is unfortunate that the characters of the different varieties had not been established before these investigations were undertaken, as it must be uncertain, unless each specimen was examined separately, whether or not the experimenters always had the same variety in hand.

[*The discussion on this paper is printed at p.* 372.]

THE PREPARATION OF LARD FOR USE IN PHARMACY.*

BY PROFESSOR REDWOOD.

I have read with much interest the paper on "Ointment Bases," communicated by Mr. Willmott to the Pharmaceutical Conference at its recent meeting, but the part of the subject which has more particularly attracted my attention is that which relates to prepared lard. Reference is made by Mr. Willmott to lard prepared in different ways, and it appears from the results of his experiments that when made according to the process of the British Pharmacopœia it does not keep free from rancidity for so long a time as some of the samples do which have been otherwise prepared. The general tendency of the discussion, as far as it related to this part of the subject, seems to have been also in the same direction; but neither in the paper nor in the discussion was the question of the best mode of preparing lard for use in pharmacy so specially referred to or fully discussed as I think it deserves to be.

When, in 1860, Mr. Hills, at a meeting of the Pharmaceutical Society, suggested a process for the preparation of lard, which consisted in removing from the "flare" all matter soluble in water, by first thoroughly washing it in a stream of cold water after breaking up the tissues and afterwards melting and straining the fat at a moderate heat, this method of operating seemed to be generally approved. It was adopted by men largely engaged in "rendering" fatty substances for use in pharmacy and for other purposes for which the fat was required to be as free as possible from flavour and not unduly subject to become rancid. It became the process of the British Pharmacopœia in 1868. In 1869 it formed the basis of a process, which was patented in Paris and this country by Hippolité Mège, for the production of a fat free from taste and odour, and suitable for dietetic use as a substitute for butter. Mège's process consists in passing the fat between revolving rollers,

* Read at an Evening Meeting of the Pharmaceutical Society of Great Britain, November 7, 1883.

together with a stream of water, and then melting at "animal heat." This process has been used abroad in the production of the fatty substance called oleomargarine.

But while there have been advocates for this process, of whom I have been one, opinions have been now and then expressed to the effect that the washing of the flare before melting the fat, was rather hurtful than beneficial. I have reason to believe that this opinion has been gaining ground among those who have carefully inquired into the properties of the products obtained by the various methods which have been suggested for obtaining animal fat in its greatest state of purity.

I have had occasion during the last two or three years to make many experiments on the rendering and purification of animal fat, and at the same time have been brought into communication with manufacturers of oleomargarine on the large scale; the result of which experience has been that I have lost faith in the efficacy of the Pharmacopœia process. I have found that in the method now generally adopted by manufacturers of oleomargarine, which is produced in immense quantities, the use of water, for washing the fat before melting it, is not only omitted but specially avoided. The parts of the process to which most importance is attached are,—first, the selection of fresh and perfectly sweet natural fat, which is hung up and freely exposed to air and light. It thus becomes dried and freed from an odour which is present in the freshly slaughtered carcase. It is then carefully examined and adhering portions of flesh or membrane as far as possible removed; after which it is cut up and passed through a machine in which it is mashed so as completely to break up the membranous vesicles in which the fat is enclosed. The magma thus produced is put into a deep jacketed pan heated by warm water, and the fat is melted at a temperature not exceeding 130° Fahr.

If the flare has been very effectually mashed the fat may be easily melted away from the membranous matter at 120° F., or even below that, and no further continuance of the heat is required beyond what is necessary for effecting a separation of the melted fat from the membranous or other suspended matter. Complete separation of all suspended matter is obviously important, and therefore filtration seems desirable, where practicable; which, however, it is not on the large scale.

My experiments tend to indicate that the process just described is that best adapted for the preparation of lard for use in pharmacy. There is, however, a point connected with this or any other method of preparing lard which is deserving of more attention than it has, I believe, usually received, and that is, the source from which the flare has been derived. Everybody knows how greatly the quality of pork depends upon the manner in which the pig has been fed, and this applies to the fat as well as other parts of the animal. Some time ago I had some pork submitted to me for the expression of opinion upon it, which had a decided fishy flavour, both in taste and smell. This flavour was present in every part, fat and lean, and it is obvious that lard prepared from that fat would not be fit for use in pharmacy. The pig had been prescribed a fish diet. Barley meal would, no doubt, have produced a better variety of lard.

[*The discussion on this paper is printed at p.* 374.]

TERRA DI SIENA, OR TERRA BOLARE E GIALLA.*

These earths, known also under the names of ochre, bole, umber, etc., are considered by some mineralogists to be ferruginous clays, by others minerals of iron. They are chiefly found in large quantities in the communes of Castel del Piano and Arcidosso (Monte Amiata).†

The yellow earths and bole found on this mountain are true lacustrine deposits, found amid the trachytic rocks, of which it is principally composed. They lie under, and are entirely covered by, the vegetable soil. Varying in compactness and colour, they are termed yellow earths when of a clear ochreous tint, and "terra bolare," or bole, when of a dark chestnut colour. Each deposit consists, for the greater part, of yellow earth, beneath which bole is found in strata or small veins. The mineral being very friable its excavation is easy, and is generally conducted in open pits. The different qualities are separated during the process; the bole, which has the higher commercial value, being the more carefully treated.

After the first separation the bole is further classed into first, second, third, and intermediate qualities—"boletta," "fascia," "cerchione," etc. Its most important characteristic is termed, in commercial language, "punto di colore," or tint. The value of the bole rises as its tint deepens. Thus bole of the third quality is lighter than that of the second, and the second than that of the first. After number three come the "terra gialla."

The yellow earths, after excavation, are exposed to the open air for about a year, by the pit side, without classification. The bole, on the contrary, is placed in well-ventilated storehouses to dry for about six months. This diversity of treatment is owing to the fact that exposure to the elements brightens the colour of the yellow earths and raises their value, while it would damage the bole, by turning its darker tint first into an orange yellow, and, if continued, into an ordinary yellow earth. It also loses in compactness and crumbles up under exposure.

In addition to the "punto di colore," the size of the pieces influences the commercial value of the bole, which increases with their volume. Thus the classification is "Bolo pezzo," "Bolo grapolino," and "Bolo polvere." The yellow earths are classed as "Giallo in pezzi," "Giallo comune," and "Giallo impalpabile," but in these cases the impalpable is worth more than the common yellow.

The production of the Siena earths may be calculated at about 600 tons per annum, of which sum 50 tons are calcined and the rest sold in their natural condition. The value of the trade may be estimated from 100,000 to 150,000 lire. A company (limited), for the working and sale of the yellow earths and bole of Monte Amiata, was formed at Siena in 1872, with a capital of 100,000 lire.

CANADIAN HONEY.‡

The large profits hitherto realized by bee-keepers have induced many others to go into the business, and, consequently, competition is now very keen. It has been said that the quality of honey has suffered thereby, and that the relationship between honey and glucose is of a too intimate kind, but these statements are not borne out by fact. Bees feed on glucose with avidity, and can be made to become mere carriers of this substance to the hive, but this course cannot be economically followed, as dysentery is induced, and the bees are lost. Glucose may be mixed with honey after the latter is taken from the hive, and in warm weather it is difficult

* From a Report by Mr. Consul-General Colnaghi on the Trade and Commerce of the Province of Siena.

† These communes, both on the western slopes of Monte Amiata, are situated in the province of Grosseto. I have included bole among the products of the province of Siena on account of the name, and because the company working the deposits has its headquarters in the city of Siena.

‡ From the *Canadian Pharmaceutical Journal*, September, 1883.

to detect, but when cold weather sets in, such honey will not crystallize, or "cand," as it is technically termed, and the glucose readily separates and prevents solidification.

There are three leading varieties of Canadian honey, named after the food of the bees in the localities where the honey is collected. These are white clover, basswood or linden, and thistle. They are equal in value, but clover honey has perhaps the preference. It is rather darker in colour than the other kinds. Buckwheat honey is produced here to some extent, but is principally confined to the Erie coast, and is used by bee-keepers for feeding purposes, being too dark in colour, and rank in odour, for table use.

Now-a-days all honey is extracted without heat, by means of a machine constructed on the centrifugal principle, the comb being uninjured. It is replaced in the hive, and, in about four days, if the "flow" is good, it is again filled by the bees, ready for treatment. In this way the same comb will last for perhaps two seasons, when, if it is dark, dirty or broken, it is melted and made into "foundation" by a machine devised for that purpose. This foundation is completed by the bees, which put on the finishing touches, and are thus relieved of all the heavy work, devoting their time to pure business. Attempts have been made to reverse matters, so that instead of the bees making wax for man, man makes wax for the bees. Paraffin has been tried as a foundation, and is received with all thankfulness, but, alas, when the heat of summer comes, the foundation melts and the house becomes a ruin. From this it will be seen that beeswax is now seldom or never collected, except for the use of the bees themselves, and Canadian wax may practically be said to be out of the market. The present supply is principally obtained from Africa, where the bee is yet unused to the refinements of civilization.

IMPROVED METHOD FOR PREPARING SCLEROTIC ACID, THE ACTIVE PRINCIPLE OF ERGOT.*

Sclerotic acid (Acidum Sclerotinicum), which was first isolated from ergot by Professor Dragendorff and Dr. Podwissotzky, and which constitutes the active ingredient of the drug, has now been in use for about eight years, and though its effects were often found to be feeble, yet it has not been entirely abandoned, it being still considered by the best authorities to be the really valuable constituent. The occasional unsatisfactory action is rather due to the fact that the substance is supplied by manufacturers in an impure condition, deeply coloured, and containing variable quantities of water, all of which naturally interfere with its uniform action.

To remove these defects, and to place in the hands of practitioners as uniform a preparation as possible, Dr. Podwissotzky has improved his method of preparation as follows:

Four hundred grams of powdered ergot are heated for three or four hours on a steam-bath with 1 litre of distilled water and 60 grams of diluted (1:7) sulphuric acid, then pressed, and the residue again extracted with 500 c.c. of distilled water for two hours in the same manner. The liquid is expressed, united with the first, the whole heated to 70° C. (158° F.), and treated with neutral acetate of lead until this ceases to yield a precipitate. This reagent throws down the erythrosclerotin as an insoluble violet-lead compound. (Erythrosclerotin yields precipitates with metals, earths, and alkaline earths; if freed from these substances it is soluble in alcohol with red colour. After an extract of ergot has been freed from erythrosclerotin, it no longer gives a precipitate with acetate of lead.)

After the liquid, together with the precipitate, has been warmed for one hour more on the water-bath, it is filtered, and the excess of lead removed from the filtrate by hydrosulphuric acid. The sulphide of lead having been separated by filtration, the straw-yellow liquid is evaporated on a water-bath (if at all possible, in a vacuum apparatus) to a syrupy consistence (to about 150 c.c.), or better still until a coffee-brown colour shows itself at the margin of the residue in the dish. (This is a sign of the *beginning* decomposition of the sclerotic acid; the dark colour, when once produced, cannot be removed.)

The residue is now briskly stirred up and mixed with $1\frac{1}{2}$ litre of absolute alcohol, whereupon the sclerotic acid will separate in ten or twelve hours. The alcohol is then poured off, another half litre of absolute alcohol poured on, with which the mass is thoroughly kneaded in a mortar. Finally, it is removed and dried over caustic lime and sulphuric acid. By repeated kneading and working with absolute alcohol, the product may be rendered dry enough to be reduced to powder.

The yield is 12 to 14 grams, and the sclerotic acid thus obtained is best preserved over lime and sulphuric acid. Or, the product may be preserved in absolute alcohol, and may also be transported or shipped in the latter.

The product is quite light coloured, not deeper than gum arabic, but it cannot be obtained entirely free from calcium and potassium salts.

While Bonjean's as well as Wernig's ergotin, when used hypodermically, produce (often?) irritation or inflammation of the connective tissue, the latter does not occur with sclerotic acid. However, a solution of the last-named does not keep long, and to obviate this, some have been in the habit of combining it with salicylic acid. This being, however, but little soluble, and sometimes separating in form of fine needles, which themselves may cause irritation, Dr. Podwissotzky recommends to use thymol-water (1:1000) for solution. In this form, the remedy has been used successfully in the Insane Asylum at Dorpat, and is also commonly dispensed by the pharmacists of the city.

When treated with alkalies or alkaline earths, sclerotic acid *loses its effects completely*, a gum-like body being then formed, while ammonia is given off.

INLAND PARCELS POST.

COLLECTION OF PARCELS BY RURAL CARRIERS.

We have been requested to publish the following:—

"Commencing on the 1st November, rural carriers, whether on foot or mounted, will be required to accept parcels from the public for dispatch wherever they now collect letters, and the collection of parcels is subject to the following regulations:—

"'(*a.*) A rural carrier on foot must not accept, from any one person, a greater weight of parcels than 7 lbs. in the aggregate, unless he shall have received notice, on the previous day, from such person of his intention to send a greater weight.

"'(*b.*) A mounted rural carrier is not required to accept a greater weight in the aggregate than 21 lbs. from any one person unless similar notice shall have been given to him.

"'(*c.*) Such notice may also be given by the sender at any post-office on the route of the rural carrier, and the postmaster of such office will inform the rural carrier.

"'(*d.*) A parcel handed to a rural carrier must be within the prescribed limits of weight and size, and must bear stamps to the full amount required for postage, the sender being held responsible that these conditions are complied with.

"'(*e.*) A rural carrier may, at the request of the sender, weigh or measure a parcel, or check the postage, when his doing so does not interfere with the proper performance of his duties, but the sender must understand that the rural carrier is not responsible for the correctness of the weight, size or postage, as this responsibility rests with the office at which the rural carrier hands in the parcel. The rural carrier may, however, refuse to accept a parcel which, beyond all doubt, is above the limits of weight or size.

"'(*f.*) A rural carrier unable to accept more parcels must explain the reason to the person who offers the parcel, and must report the circumstance at the next sub-office on his route, and also to the postmaster of the terminal office.'"

The Pharmaceutical Journal.

SATURDAY, NOVEMBER 10, 1883.

Communications for the Editorial department of the Journal, books for review, etc., should be addressed to the Editor, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to Mr. Elias Bremridge, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, Messrs. Churchill, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

THE WEIGHTS AND MEASURES ACT.

An annual report by the Board of Trade on its proceedings and business under the Weights and Measures Act has been issued during the past week, which although somewhat shorter and less exciting than some of its predecessors deals with one or two topics of interest to all persons in the habit of using weights and measures for the purposes of trade, whilst it is accompanied by an appendix of considerable scientific value. The report itself once more reflects in several places the powerlessness of the Board under the Weights and Measures Act to exercise authority, its function in this direction being limited to tendering advice in respect to subjects of complaint and inquiry. One of the questions that have been under the consideration of the Board relates to the practice of inspectors in respect to conical glass measures. It is stated that whilst in some of the principal districts of verification inspectors refuse to verify and mark for use in trade glass measures that contain more than a certain number of graduations or subdivisions—how many is not stated—in other districts inspectors pass them so overcrowded with graduations that in the opinion of the Board the intention of the Act is defeated and the use of accurate measures discouraged. A suggestion has therefore been communicated by the Board to the local inspectors that glass measures with an excess of graduations should not be verified, and it is hinted that it is a matter of grave doubt whether a local inspector would be justified in passing for use in trade measures graduated with more than the limited number of denominations marked on the Board of Trade conical glass standard measures. Another subject which has been brought under the notice of the Board, by the local authority of Glasgow, is the question of empowering inspectors to adjust weights and measures brought to them to be verified and found to be incorrect, and to charge a fee for the operation. It has been urged that although the Act takes no cognizance of adjustment, it is much more convenient that the inspector should adjust weights and measures found defective by him, otherwise it might become necessary to carry them to and fro several times before they were passed as agreeing with the standards. The fact of this representation is simply reported without comment, and it is easy to perceive that any such provision could hardly be made absolute, but would have to be surrounded with safeguards for the protection both of the public and the inspectors. Other representations that have been made to the Board concerned the desirability that uniformity should be established in the fees taken by different local authorities for stamping weights and measures under the Act, and also a grievance felt by some inspectors that they are not empowered to extend their testings to packages of goods which are alleged to contain a specific weight or measure.

Some doubt having arisen as to the standard kilogram in the possession of the Board of Trade, it was deemed advisable that a comparison of this unit of metric weight with some other authoritative standard should be made. Here some little difficulty occurred, as the original standard of metric weight, the "kilogramme des archives," has been admitted by the highest authorities to be incorrect, and the foreign standard possessing the greatest authority is that recently made and verified under the direction of the Comité International des Poids et Mesures, on which committee this country is not represented. By the courtesy of the President, however, this standard was made available for the comparison, and the English standard kilogram, which, when originally constructed in 1842, was found to be 1·563 milligrams too light, now proves too be 2·0178 milligrams deficient. It may be hoped that as the Board of Trade acknowledges its previous indebtedness to the results of the scientific researches carried out under the directions of this Committee our Government will see the propriety of contributing towards the payment of the expenses incurred, since it is hardly dignified for Great Britain to continue seeking *in formâ pauperis* boons so closely associated with its commercial interests. Another useful piece of work that has been done by the Board is to carry into effect the provision in the Act of 1878 to avoid the continual use, and probable constant wear, of the imperial standard of weight, by having made an accurate copy of the imperial standard pound. The new copy is similar in form and material to the standard, with the exception that a small proportion of iridium has been mixed with the platinum, as it was considered desirable that it should consist of a rather harder metal than the original. It is intended that this copy shall in future be used instead of the standard in all ordinary weighings conducted by the Standards Department. The Board of Trade has also had the opportunity during the past year of assisting the United States Government by making a comparison of the United States standard of length—a yard—with the British yard standards deposited in the office; the result was that the United States standard proved to be 0·000022 inch longer than the British. A second application from the same Government had to do with a doubt raised as to the ancient measurement of land in a city of the United States, involving the question when the present foot measure was established in that country and whether it may have appreciably differed at any time from the foot measure of Great Britain. The subject is not without historical interest and is discussed in a memorandum that will be attractive to persons of metrological and antiquarian proclivities. It must, however, suffice here to say that although it is difficult to give the precise date at which the present standard foot was introduced into the United States it is considered to be quite clear that it does not and never has differed appreciably from the third part of the English standard yard.

The Report also shows that the Board of Trade recognizes the necessity of keeping abreast of the progress of science by giving a formal sanction to and thus establishing new units of measurement as they are required. The enormous development in the practical application of electrical science to lighting and other purposes, which found legislative recognition last year in the Electric Lighting Act, has necessitated the adoption of some uniform unit of measurement of electrical energy, and it is stated that in the provisional orders under this Act a unit has been taken which is equivalent to the "energy "contained in a current of one thousand ampères "flowing under an electromotive force of one volt "during one hour." Whilst, however, the unit of measurement may be looked upon as thus settled, no practical meter of electricity capable of use in commerce and daily life has yet received official sanction. The attention of the Board has also been called to an analogous subject in the defects in the existing rules for testing gas meters as well as the want of a uniform standard of light, and it expresses the opinion that on these and other points legislation is desirable.

We have already spoken of the scientific value of the appendix to the Report, and this is especially manifest in a series of tables for the calculation of densities and expansions, which have been drawn up for future use in the Standards Office in consequence of the tables hitherto in use not having been found in accord with the most recent scientific research. These new determinations will no doubt be looked upon as a boon by many investigators, since the series includes tables showing the maximum pressure of aqueous vapour at different temperatures, ratios of densities of water and air, corrections necessary when weighing a gallon or a litre of water at different temperatures in glass or brass containing vessels, a table of the specific gravities of nearly one hundred substances, and several tables relating to the coefficients of expansion of a number of metals, glass and other substances at different temperatures. There is also a table of suggested allowances for variations of the barometer for use in petroleum testing. It will be evident, therefore, that the present Report shows no falling off in the quality of the work done by the Standards Department of the Board of Trade.

Reference is made in the Report to a decision under the Weights and Measures Act in the Appeal Court at Edinburgh, which seems to be open to remark in respect to the ground of the decision of one of the judges, which might prove misleading. The point in dispute was whether a "glass" is to be deemed a definite quantity. Lord YOUNG held that if a man asks for a "glass" he is in a sense buying by measure, but it is not by any known measure, local, customary or imperial. We think, however, it should be borne in mind that under the 19th section of the Act even local and customary measures are made illegal, and any person who sells by any denomination of weight or measure other than one of the imperial weights or measures, or some multiple or part thereof, is made liable to a fine. The Lord Justice Clerk was of opinion that in the sale of beverages by the glass the contract was one by price and not by measure, and this seems to us to be the sounder view of the case.

The first Evening Meeting of the North British Branch of the Pharmaceutical Society for a new session will be held in the Society's Rooms, 119A, George Street, Edinburgh, on Wednesday evening next, the 14th inst., at half-past eight o'clock, when the President of the Branch (Mr. John Nesbit) will deliver an address, and a paper, entitled "Hints to Young Pharmacists," by Mr. George Burrell, will be read.

* * *

The School of Pharmacy Students' Association will recommence its meetings on Thursday evening, the 15th inst., when the chair will be taken at 8 p.m. by the President, Professor Attfield, and an address will be delivered by Mr. Joseph Ince, the subject of which will be "Science, its Abuse and Use." At this meeting, also, the election of officers for the present session will take place. As most of our readers are aware, one of the principal objects of this Association is the encouragement of original investigation in pharmaceutical subjects by the members, and to afford aid in this direction a Research Fund has been established. We have reason to believe that there are those who are desirous of helping to augment this Fund; we would therefore mention that as it is maintained solely from the balance from the subscriptions of members, this purpose can be best attained by joining the Association, all past and present students of the School of Pharmacy being eligible for membership.

* * *

On Thursday, the 1st inst., the Edinburgh Geological Society celebrated its jubilee year by a Conversazione in the Museum of Science and Art, which was attended by representatives from no less than forty-seven societies existing in Scotland, among whom were the President (Mr. Nesbit) of the North British Branch of the Pharmaceutical Society and several members of the Council. In the course of the evening an able and interesting address was delivered by the Duke of Argyll on the Uniformitarian Theory.

* * *

An extraordinary crime is reported to have been perpetrated in a pharmacy in Strassburg early in the morning of the 23rd of October. About on o'clock the assistant on night duty went downstairs to the shop in consequence of the ringing of the night-bell by a person who said he wanted a prescription made up. Shortly afterwards the principal was surprised by the sounding of an electric bell in his room, and upon descending he found his assistant dreadfully mutilated and at the point of death. It is conjectured that the assistant, seeing the pretended customer in the act of raising an axe, tried to escape by running to a back room and touched the electric bell as he passed; but it would appear that the assassin was too quick for him and struck him down with repeated blows. The murderer, unfortunately, got clear away, taking the till with a small sum of money in it. M. Lienhardt, the victim, was forty-two years of age and leaves a widow and two children, for whom a fund is being raised.

* * *

The *Glasgow Medical Journal* for November contains a note on a case of lightning stroke, by Mr. J. Yule Mackay, which is made doubly interesting by a capital photograph, showing the curiously ramified markings produced upon the skin of a boy's arm by the action of the electric fluid. Similar cases have been previously reported; but we believe this is the first time that a permanent record of the marking has been secured, and we note with interest that this perpetuation is due to the intelligent promptitude of Mr. William Gunn, pharmaceutical chemist, of Dunse, the father of the boy, who had a photograph taken within four hours of the accident, before the phenomenon had had time to disappear.

* * *

Some time since a druggist residing in Brooklyn, who had been annoyed by boys mischievously ringing his night-bell and running away, let his anger get the better of his discretion, and lying in wait with a stick until the next ring came rushed out and thrashed—a customer! The consequence has been an action for damages, which were laid at two thousand dollars; only fifty dollars have, however, been awarded.

* * *

On Saturday evening last an extensive fire broke out in a warehouse in Buchanan Street, Glasgow, and we are sorry to notice that before it was extinguished the premises occupied by Messrs. Thomas Davison and Son, Chemists and Druggists, were involved in the conflagration.

* * *

The sessional arrangements of the Society of Arts include six series of Cantor Lectures, which will be delivered in the following order:—(1) "The Scientific Basis of Cookery," by Mr. W. Mattieu Williams; (2) "Recent Improvements in Photo-Mechanical Printing Methods," by Mr. T. Bolas; (3) "London Houses," by Mr. R. W. Edis; (4) "The Alloys used for Coinage," by Professor W. Chandler Roberts; (5) "Some New Optical Instruments and Arrangements," by Mr. J. Norman Lockyer; and (6) "Fermentation and Distillation," by Professor W. Noel Hartley. The Juvenile Lectures are to be on "Crystals and Crystallization," and delivered by Mr. J. Millar Thomson.

* * *

At the meeting of the Chemical Society held on Thursday evening next, papers will be read on "The Estimation of Starch," by C. O'Sullivan, and on "The Products of Decomposition of Solutions of Ammonium Nitrite," by G. Stillingfleet Johnson.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, November 7, 1883.

Present—

MR. MICHAEL CARTEIGHE, PRESIDENT.

MR. SAMUEL RALPH ATKINS, VICE-PRESIDENT.

Messrs. Andrews, Bottle, Butt, Churchill, Gostling, Greenish, Hampson, Hills, Radley, Richardson, Robbins, Savage, Schacht, Squire, Symes, Woolley and Young.

The minutes of the last meeting were read and confirmed.

The Council went into committee for a short time to discuss some matters arising out of the minutes. On resuming,

Mr. SYMES, referring to the motion which he brought forward at the last meeting respecting an exhibition, said he should not, of course, attempt to raise that question again, but it had occurred to him since, that as new cases had been fitted up in the examination room which would probably relieve the cases in the Museum of some of the articles contained in them, a modified form of Mr. Schacht's original proposal for exhibiting pharmaceutical apparatus might be carried out. He would suggest that the Library and Laboratory Committee should consider the subject.

The PRESIDENT said he would bring the subject before the Committee at its next meeting.

Mr. GREENISH said the Curator had already obtained permission to appropriate a portion of the Museum to the exhibition of novelties.

The PRESIDENT said the Curator's application did not refer particularly to new apparatus, but that point should be considered.

Mr. SYMES said he had been informed by the Curator that when pharmacists visited the Museum they often asked what there was new, and were not always satisfied with seeing new drugs or plants with long names, but were anxious to know what was moving in connection with pharmacy.

Mr. SCHACHT suggested that the Committee might consider the desirability of parting with some of the old pieces of apparatus which might not be of much service.

DIPLOMAS.

The following, being duly registered as Pharmaceutical Chemists, were respectively granted a diploma stamped with the seal of the Society:—

Evans, Evan James.
Jones, Frank.
Longtoft, William.
Ord, Septimus William.
Pirie, William.
Puckey, Courtenay.

ELECTIONS.

MEMBER.

Pharmaceutical Chemist.

Evan James Evans, of Clevedon, having passed the Major examination and tendered his subscription for the current year, was elected a "Member" of the Society.

ASSOCIATE IN BUSINESS.

William Wrench Blades, of Wandsworth, having passed the Minor examination, being in business on his own account, and having tendered his subscription for the current year, was elected an "Associate in Business" of the Society.

ASSOCIATES.

The following, having passed the Minor examination and paid as Apprentices their subscriptions for the current year, were elected "Associates" of the Society:—

Baxter, William ....Bromley.
Briggs, George William ....Bulwell.
Clayton, George ....Manchester.
Cole, William ....West Cowes.
Doubleday, Frederick William..Norwich.
Fletcher, Francis Round ......Netherton.
Harold, John Patrick ....London.
Hedley, Charles Alfred ....South Shields.
Jackson, Harold ....Manchester.
Loeffler, George Berthold ......London.
Mann, William.................. ..Leicester.
Marshall, Sam ....Hyde.
Maxton, William ....Edinburgh.
Mitchell, Thomas Maxwell......Leeds.
Mowat, John Watt ....Coatbridge.
Nobbs, Arthur Perkins ....Newport, I.W.
Notcutt, William Brighty ......London.
Owen, David James...............Swansea.
Price, Charles Cleaver............Bristol.
Price, Henry Thomas ....Shrewsbury.
Pumphrey, Arthur ....York.
Reade, Leonard James ....Wolverhampton.
Rutherford, Fredk. Arthur R. ..Bristol.
Sharp, John ....Galashiels.
Sharp, Stephen.....................Heywood.
Smout, Charles Lickfold.........London.
Turner, John Edward.......... ..Woodbridge.
Wokes, Thomas Siminson ......Hull.
Woodruff, Albert Edward ......Sandwich.
Wrenn, William Albert ....Penge.

APPRENTICES OR STUDENTS.

The following, having passed the Preliminary examination and tendered their subscriptions for the current year, were elected "Apprentices or Students" of the Society:—

Burnett, Augustus Frederick...Highbridge.
Huskisson, Owen Dudley ......London.
Jackson, John Thomas ....Scotforth.
Lewis, Thomas ....Llancain.

Several persons were restored to their former status in the Society upon payment of the current year's subscription and a fine.

Mr. SCHACHT asked why the amount of the fine of one of the gentlemen who was to be restored to membership was greater than the others?

The PRESIDENT said because he had been longer in arrear.

The Council went into committee to further discuss this question.

REPORTS OF COMMITTEES.

FINANCE.

The report of this Committee was received and adopted and various accounts were ordered to be paid.

The PRESIDENT gave a summary of business that had been transacted in connection with the investments in freehold ground rents.

Mr. ROBBINS said it might be satisfactory to the Council to know that other societies were following the same course with regard to investments. He found that during the last year the Society of Arts had sold out stock and invested the money in freehold ground rents.

BENEVOLENT FUND.

The report of this Committee included a recommendation of the following grants:—

£10 to a former member, aged 64, suffering from chronic illness.

£10 to the widow of a registered chemist and druggist, who has had two previous grants.

£10 to the widow of a registered chemist and druggist.

£10 to a registered chemist and druggist.

Several applications the Committee declined to entertain, and one had been deferred for further information.

The report and recomendations were received and adopted.

LIBRARY, MUSEUM, LABORATORY, AND HOUSE.

Library.

The report of the Librarian had been received, including the following particulars:—

Attendance.		Total.	Highest.	Lowest.	Average.
July	Day	561	38	7	21
	Evening	122	10	1	5
August	Day	61	10	0	2
September	Day	57	9	1	5 nearly

Circulation of books.	No. of Entries. Town.	Country.	Total.
July	150	111	261
August	62	43	105
September	52	100	152

Carriage paid:—	£	s.	d.
July	1	13	5
August	0	14	7½
September	1	9	1

The Librarian had also reported that in making the annual inspection of the Library, he had found that the undermentioned books were missing:—

Bentley's Elementary Botany.
New Remedies, vols. 9–10.

The tenth volume of the Journal of the Chemical Society, reported missing some years since, had been returned to the Library. Three volumes, lost while on loan, had been paid for by the borrowers.

The undermentioned donations to the Library had been received, and the Committee recommended that the usual letter of thanks be sent to the respective donors:—

Riverius (L.), Practice of Physic, 1678.
From Mr. T. GREENISH.

Martindale (W.), and W. W. Westcott, The Extra Pharmacopœia, 1883.
From Mr. H. K. LEWIS, Publisher.

India, Revenue and Agricultural Department, Collection of Papers on Bee-keeping in India, 1883.
From H.M. SECRETARY OF STATE FOR INDIA.

Méhu (C.), Sur la redissolution des pigments de l'urine, 1883.

Sutton (F.), Manuel systématique d'analyse chimique volumétrique, 1883. From Dr. MÉHU.

Institution of Civil Engineers, Charter, By-laws, and list of members, 1883. From the INSTITUTION.

Working bulletins for the Scientific Investigation of the Newer Materia Medica, vol. 1, 1883.
From Messrs. PARKE, DAVIS and Co.

Flückiger (F. A.), Pharmakognosie des Pflanzenreiches, 2e Aufl., 3e Lief, 1883. From the AUTHOR.

Plugge (P. C.), Über die Warscheinlichkeit einer Veränderung des Strychnins in dem thierischen Organismus, *etc.*, 1883. From the AUTHOR.

Chicandard (G.), La fermentation panaire, 1883.
From the AUTHOR.

Schär (E.), Die wichtigsten Genussmittel fremder Völker, 1877–8.
— Die Farbstoffe des Alterthums und der Neuzeit.
— Die ältesten Heilmittel aus dem Orient, 1877.
— Botanischer Congress (Abtheilung: Chinarinden) und Austellung pharmaceutisch wichtiger Pflanzenproducte zu Amsterdam, im April, 1877.
— Über verschiedene Reactionen der Kupferoxydsalze bei Gegenwart von Cyanverbindungen, 1869.
— Nachtrag zu den Beobachtungen über die Guajak-Kupfer-Reaction, 1870.
— Über die Knollen von Flüggea japonica, 1874.
— Notizen über Cubebencampher, 1875.
— Bemerkungen zu der Salzsäure-Reaction bei der Prüfung des Arrow-Root, 1875.
— Über Cortex Quebracho, 1881.
— Notizen über Oleum folior. Cinnamom. ceylan., 1882.
— Chemische Bemerkungen zur Berieselungsfrage.
— Die Chemie in Dienste der öffentlichen Gesundheitspflege, 1877. From the AUTHOR.

The Committee recommended the purchase of the undermentioned books:—

Martindale (W.) and W. W. Westcott, Extra Pharmacopœia, 2nd ed. 2 *copies.*

Haldane (R.), Workshop Receipts, 2nd series.

Dragendorff (G.), Plant Analysis, translated by H. G. Greenish.

Landolt (H.) and R. Börnstein, Physikalisch-chemische Tabellen.

Bentley (R.), Elementary Botany.

The Librarian had presented his report on the sixth annual meeting of the Library Association of the United Kingdom, held in Liverpool, September 11 to 14.

Curator's Report.

The Curator had reported the attendance in the Museum during July to have been:—

	Total.	Highest.	Lowest.	Average.
Morning .	415	32	3	16
Evening .	95	10	1	6

The following donations to the Museum had been received, and the Committee recommended that the usual letter of thanks be sent to the respective donors:—

Herbarium specimens of the Siam Benzoin tree, without flowers or fruit. Sections of the trunk of the Siam Benzoin tree.

Herbarium specimen of the Sumatra Benzoin tree, with leaves, flowers and fruit.

Flowers and immature fruit, preserved in spirit, of the Sumatra Benzoin tree and dried mature fruit of the same tree.

Leaves of the Gamboge tree, both male and female, and flowers and immature fruit of the same preserved in spirit, and sections of the trunk of the tree.

Fruits of the Balsam of Peru tree grown in Singapore, and a specimen of the oil distilled from the seeds.

Specimens of both Black and White Rasamalas.

Specimen of Camphor made from *Blumea balsamifera.*

A piece of the wood of Liquidambar Altingia.

Sample of Minyak Tangkawang or Vegetable Tallow from Borneo.

Seeds of the Vegetable Tallow tree from Sarawak.

Seeds of the Vegetable Tallow tree from Pontianak.

From Mr. R. Jamie, Singapore.

A fine collection consisting of 145 specimens of Japanese drugs; a specimen of Ogea Gum; also specimens of drugs from Sierra Leone.

From the Director of the Royal Gardens, Kew.

Twelve specimens of Brazilian Drugs.

From Messrs. Christy and Co.

Poisonous points prepared from the seeds of *Abrus precatorius.* From Mr. Boverton Redwood.

Specimens of genuine *Ledgeriana* bark (C. *Calisaya*, var. *Ledgeriana*, How.), and of Red Bark, illustrating the paper in the *Pharmaceutical Journal* on Red Bark grown at different altitudes.

From Mr. J. E. Howard, F.R.S.

Specimens of the fruits, leaves and flowers of *Chailletia toxicaria*, a rat poison used in West Africa.

From Dr. W. Renner.

Specimen of a fragrant resin with the odour of Angelica, from the Solomon Islands.

From Mr. R. Reynolds, of Leeds.

The Professors had attended the Committee and reported satisfactorily of their respective classes.

The Committee had considered the question of appointing an assistant to the Curator and recommended that a person should be engaged who would make himself generally useful, rather than one of scientific attainments, and that the appointment should be left in the hands of the President and Curator, subject to an approval by the Committee at the next meeting.

The question of commutation of arrears of subscriptions had also been considered, and the Committee recommended that no alteration be made in the instructions given to the office.

On the motion that the report be adopted—

Mr. Schacht proposed to discuss the question referred to in the last paragraph and began to state the information which the Committee had received from the Assistant Secretary on the subject, when it was proposed and carried that the Council go into committee to discuss this topic.

On resuming, the report and recommendations of the Committee were adopted.

GENERAL PURPOSES.

The report of this Committee included the usual letter from the Solicitor reporting the progress made with cases which had been put in his hands. A penalty of £5 and costs had been paid into court by

F. Bradley, 161, York Street, Hulme, Manchester.

Several new cases of alleged infringement of the Pharmacy Act, had been brought before the Committee and in most of them it was recommended that a prosecution be instituted. A case of appeal from the Registrar's decision refusing to place a certain name on the Register had come before the Committee, and had been deferred for further investigation.

Pharmacy Acts Amendment Bill.

A Deputation from the Executive Committee of the Chemists and Druggists' Trade Association had waited on the General Purposes Committee, which consists of the whole Council, in order to communicate its views with regard to the proposed Pharmacy Acts Amendment Bill. The Deputation consisted of—

Mr. John Harrison, President.
Mr. W. G. Cross, Vice-President.
Mr. Thomas Barclay.
Mr. A. H. Mason.
Mr. Owen Jones.
Mr. G. H. Laird.
Mr. George Walker.
Mr. W. F. Haydon, Secretary.

This report was, as usual, considered in committee. On resuming, the report and recommendations were received and adopted.

REPORT OF EXAMINATIONS.

October, 1883.

ENGLAND AND WALES.

	Candidates.		
	Examined.	Passed.	Failed.

9 University of Cambridge.
1 " Durham.
3 " Edinburgh.
1 " London.
2 " Oxford.

EVENING MEETING.

Wednesday, November 7, 1883.

MR. MICHAEL CARTEIGHE, PRESIDENT, IN THE CHAIR.

The second Evening Meeting of the session was held on Wednesday, the 7th inst., at half-past eight o'clock.

The minutes of the last meeting having been read and confirmed, a paper was read on—

THE CLASSIFICATION AND PROPERTIES OF RED RESINS KNOWN UNDER THE NAME OF DRAGON'S BLOOD.

BY J. J. DOBBIE AND G. G. HENDERSON.

The paper is printed at p. 361, and gave rise to the following discussion:—

Professor BAYLEY BALFOUR said dragon's blood was a substance of practically little importance at the present day, but it was frequently referred to by the older writers and travellers,—Marco Polo, for instance,—and it was considered in those days as a panacea. It was formerly an important article of commerce in the East, and also between the Portuguese and the Canary Islands. Now, however, it was very little used, except perhaps for colouring tooth powders, and he believed coachbuilders also used it as a colouring matter. If, however, it was not of much practical importance it had a considerable interest from the antiquarian and botanical point of view, because the true dragon's blood was obtained from plants of the genus *Dracœna*, etc., and the species which yielded it were only found in a few localities, and these at wide intervals over the surface of the globe. There were many kinds of dragon's blood in commerce, as had been pointed out, but the genuine specimens were all obtained from some member of the genus *Dracœna*. One kind very much in commerce was the red dragon's blood, obtained from the *Calamus*, a species of palm, but it was quite different from that obtained from the *Dracœna*. The oldest mention of this substance was by Dioscorides, who referred to a substance which he called "kinnabari," as being brought from the island of Dioscoris, which had been identified with the island of Socotra. Socotra was at the extreme north-east corner of Africa, and had been identified by M. Marriette as the Islands of the Sea referred to in Scripture. M. Marriette had found on a Theban monument a representation of the ambassadors of one of the old queens of Egypt, who were sent to a place called To Nuter, and he had identified the Archipelago of To Nuter with the Island of Socotra. Curiously, however, this island, although so well known in ancient times, seemed to have dropped out of knowledge, and at the present day hardly one in a hundred knew where it was. A few years ago he went to examine the fauna and flora of the island, and brought back with him amongst other things specimens of dragon's blood. This "kinnabari," which Dioscorides mentioned, was obtained from a species of *Dracœna* that grew on the island, belonging to the family of the Liliacæ. All the species of that genus did not yield a resin, but four only, which belonged to a very peculiar type of the family, a very old type which branched very freely and formed a thick trunk, and of which there were very few representatives at the present day. He had drawings of the tree and also a number of the leaves which he would pass round. The peculiarity of this species was that not only did the trees branch freely but the leaves were curiously stiff and sword-like, and it formed a very thick stem. Many would no doubt have heard of the famous dragon's blood tree of Orotava in Teneriffe. The resin was used by the Guanchos for the purpose of embalming. The genus *Dracœna* was peculiar amongst all monocotyledonous plants from the fact that the stem showed a great secondary growth in thickness, arising from a formation of new tissue. The *Dracœna* of Orotava attained the height of about 60 ft., and a circumference of 48 feet; unfortunately, it was blown down in 1868. The resin was secreted from the stem in the form of tears, exuding naturally from small cracks or crevices, and forming a large red mass. In Socotra it exuded most abundantly immediately after the rainy season. [A specimen was shown exhibiting the resin adhering to the tree.] The natives of Socotra collected it by chipping off the resin with a knife into a small bit of skin placed against the tree; and there were different qualities collected. First of all there were the large tears, which was the best form and most expensive, which they called *edah amsello.* Naturally, in breaking it off small portions became detached, which were collected, and formed a small powdery dragon's blood known as *edah dukkah*; and thirdly, in order to prevent any loss, they melted the refuse into cakes, which were afterwards broken up into smaller masses and called *edah mukdehah.*, which was the cheapest kind. This was the true dragon's blood as collected in the Island of Socotra, which was meant by Pliny and many other old authors. That obtained in the Canary Islands was of much the same character, but the species of tree was quite different, being known as the *Dracœna Draco*. For a long time it was considered the only dragon's blood tree; but not many years ago, when Miss Tinne made an expedition into the interior of Africa, she went up to the source of the Bahr el Ghazal River and discovered there another branching *Dracœna*, which yielded a kind of dragon's blood. She brought home specimens, which were described as *Dracœna Ombet*, but no resin had been obtained from that tree. Dr. Schweinfurth also brought the same tree from Suakim and there was no doubt that it was a distinct resin-yielding tree; though as yet the character of the resin had not been determined. Later, Hildebrand, in travelling to Zanzibar, found on the Somali Coast another species of resin-yielding *Dracœna*, which he brought home and it was described as *Dracœna schizantha*; but the resin had not yet been examined. There were thus four distinct species of *Dracœna*, all yielding apparently a distinct resin. The only resins, however, of which they possessed specimens were from the Canary Islands (*Dracœna Draco*) and from Socotra (*Dracœna Cinnabari*). It was very curious that four trees should be found all belonging to this peculiar old type of vegetation, existing in such different places, and that was one of the most interesting facts concerning the distribution of plants in these regions. One of the most interesting subjects of botanical speculation was the origin and development of the flora on the highlands of Africa. It might be known to some that at the Cape and on the West Coast about Angola, and also in the north-western parts and in the Canary Islands, as well as in the highlands of Abyssinia, Nubia and Somali, there were found a number of plants which closely resembled one another; in some cases they were specifically alike, and in others generically; and it was an interesting problem to account for the extraordinary distribution of these genera and their absence in the intermediate localities. One could not account for it by the fact that the intermediate land had not been properly explored, because these plants were only found on the higher lands, and the only explanation seemed to be, that these were the remains of a very old African flora, which once peopled the greater part of the continent, at a time when the climate was very much colder than at present. As the ice in the ice age gradually receded northward and the climate got warmer, these plants were gradually driven upwards to higher regions and both northwards and southwards, and the result was that at the present day, on the high peaks of South Africa, in the Canary Islands, and in the other places he had mentioned, the remains were found of the old flora which, by climatic changes, had been gradually driven out and replaced by more tropical plants. As yet no *Dracæna* had been found in South Africa, but it would not be surprising if one were found on the higher lands there. He might also recall to the recollection of the meeting that the Island of Socotra, which though it lay in the pathway of civilization had yet been so long unknown, yielded a very important drug, the Socotrine aloes. It was supposed by many to take its name from the island, though others derived it in a different way; but there was no doubt that the true Socotrine aloes came from Socotra, though it was not until four years ago, when he visited the island, and was able to obtain and bring home specimens, that the plant which yielded it had been properly described. The plant had been named *Aloe Perryi* by Baker, who identified a leaf brought home by Commander Perry some years previously, and there were several plants now to be seen growing in Kew Gardens. Another important point in connection with this island was the occurrence upon it of a great number of myrrh and olibanum trees. The sources of true myrrh and olibanum had been long disputed; the true myrrh plant was now pretty well ascertained, but there was little doubt that amongst the myrrhs sent into the markets in the East, a great number were spurious. There had also been a great deal of discussion as to the locality of Sheba, the queen of which paid the visit to Solomon and as to the Islands of the Sea; but this identification by Marriette of the Island of Socotra with the Archipelago of To Nuter, as being the place where the Queens of Egypt sent ambassadors to procure myrrh and olibanum, would tend to show that probably Socotra may have been one of the great myrrh and olibanum-producing countries, whence the ancients procured those substances; it was interesting, therefore, to ascertain whether there were any botanical support for that view. It was found that in Socotra there were a great number of myrrh and olibanum plants. The olibanum-yielding genus (*Boswellia*) had hitherto been considered to contain only four species, but in Socotra three special species were found, so that the island contained more species of that genus than any other area of like extent. In the same way the genus *Balsamodendron*, the myrrh-yielding plants, had three distinct representatives in Socotra, and there were probably two more, so that it must in past times, when the commerce with adjacent countries was greater than at present, have supplied many of the markets of the East with these substances.

Professor Bentley desired to offer his thanks to Professor Bayley Balfour for the interesting account he had given of the botany of the species of *Dracæna*, which yielded either the Socotrine dragon's blood or those which they had reason to believe yielded a red resin, which, perhaps, although not altogether authenticated, would be found to be essentially the same in character with that which had been described to-day from the Island of Socotra. They were also much indebted to Professor Balfour for being the first to authenticate the real source of that very important drug, Socotrine aloes; and his investigations generally with regard to the Island of Socotra, of which he had given a short abstract, showed how thoroughly he had explored it. It was quite true that dragon's blood was not a subject of much practical interest, being very little used, at least, in this country, but it was a substance of which they had the very earliest records, finding it mentioned as a matter of commerce between the Arabians and Chinese, along with such substances as olibanum, myrrh and liquid styrax. It was rather remarkable that even at that time the Chinese were the great users of dragon's blood, and at the present day he believed this was still the case. They did not get it now, however, from the *Dracæna Cinnabari* of Socotra, but from Sumatra, where it was derived from the *Calamus*. Practically, the only kinds of dragon's blood of which they had any special knowledge were those from *Calamus* and *Dracæna*. There were a great number of the specimens in different museums which had no authentication, and it was very doubtful whence they were derived. There were one or two interesting chemical facts with regard to these resins. It was generally stated that all kinds of dragon's blood contained iron, and he should like to know whether the gentlemen who had investigated these resins had tested for iron. But the matter of greatest interest was the benzoic acid. It had always been said that *Calamus* dragon's blood contained benzoic acid, and one of the tests given by which to distinguish the Socotrine dragon's blood from that of Sumatra was that the Socotrine resin did not evolve benzoic acid when heated. That was the test given in most works of repute, such as Flückiger and Hanbury's. The investigations of the authors of the paper now under discussion proved, however, that dragon's blood contained no benzoic acid. It also appeared from the present paper that the specimens in Class I., which appeared to be well authenticated, and which probably all came from the *Calamus*, contained cinnamic acid. The specimens in the fourth class were said to come from *Calamus Draco* (Bombay) and from the Punjaub: and these, as well as two well authenticated species, the *Dracæna Draco* and *D. Cinnabari*, contained no cinnamic acid. It thus appeared that the resins of *Calamus Draco* from Bombay and the Punjaub were said to contain no cinnamic acid, while that of *Calamus Draco* from Sumatra did contain that acid. He thought that could easily be accounted for, as it was pointed out with regard to the resins exported from Bombay, and said to be from *Calamus*, that they probably came first from the east coast of Africa. He should have said there could be no doubt about it. He believed it was mentioned by Hanbury without question that the so-called Bombay kind was obtained from Africa, and probably from Socotra. In Professor Balfour's interesting paper at the British Association he had referred to the commerce between the Island of Socotra and Zanzibar, and from Zanzibar many articles of commerce went to Bombay, so he thought there could be little doubt that the variety which was said to be from *Calamus Draco* was really from a *Dracæna*, and if so that explained the discrepancy. He should not be at all surprised to hear that authentic specimens from *Dracænas* would have no cinnamic acid, whilst those from *Calamus* would be found to contain it.

Mr. Umney said it was quite unnecessary to apologize for this very interesting paper, and the remarks Professor Balfour had been kind enough to make, on the ground that dragon's blood was so little used. It was quite true it was little used in medicine, but it was largely used in the arts; certainly, at least 50,000 pounds weight reached this country annually. This only showed how little was really known of dragon's blood, and he must say that when one saw the large piles which were exposed weekly for sale, it almost made one ashamed to handle a thing of which he knew so little. The meeting was much indebted to the gentlemen who had investigated the chemistry of the matter and also to Professor Balfour, who had brought forward such interesting facts in connection with its botanical distribution.

Mr. Holmes said he was sure that if Mr. Hanbury had been alive he would have been exceedingly delighted with this paper, having paid considerable attention to the subject of dragon's blood, as might be gathered from the remarks in the 'Pharmacographia.' Professor Balfour had shown that of the dragon's blood there were four different classes, two of which were obtained from plants of which nothing whatever was known, whilst at the same time he had cleared up the difficulties which even Mr. Hanbury was obliged to acknowledge for want of further information with regard to the properties of the dragon's blood from the *Dracænas*. The fact that the dragon's blood from all the *Dracænas* which are known to yield the resin had very similar properties, so that they could all be put into one group, was also an addition to our knowledge of the subject. One point came out in the first table, which was of some importance. Mr. Umney had shown that dragon's blood was largely imported into this country, but in Class IV. it was pointed out that some Socotra dragon's blood had gone to India, and as far as the Punjaub, showing that although it might not be much used here as medicine, it was probably largely so used in India. The collection in the Indian Museum, a portion of which had been handed over to the Pharmaceutical Society, contained a large number of specimens of dragon's blood, showing that it was much used in various districts in India.

Professor Bentley said he believed it was used in this country for staining marble.

Mr. Umney said it was also used by French polishers.

Mr. Moss said Professor Balfour had made one or two interesting remarks on Socotrine aloes, and he should like to ask him if he could say how it was that now-a-days they never met with the deep-coloured Socotrine aloes they were accustomed to ten years ago, aloes which broke with a beautiful glassy fracture, translucent and red at the edges. That which they now met with usually came in monkey or goat skins and broke with a dull fracture. If it were not in those skins it was in an almost liquid state. He was surprised to hear Professors Bentley and Balfour speak of dragon's blood as being of so little consequence, for probably neither of those gentlemen had a piece of polished mahogany in his house which did not owe a great deal of its beauty of colour to this substance.

The President then proposed a vote of thanks to the authors of the paper, who, he said, had done an immense amount of work in examining these specimens; they were, therefore, especially grateful to these officers of the University of Edinburgh for investigating these resins. When he came to the botanical part of the subject he felt personally it was a great mistake that he was a pharmacist, and not a botanist, for he should like to wander over the world looking for fresh specimens, and at all events endeavouring to add to the sum of botanical knowledge. He must, therefore, include in the vote of thanks, Professor Balfour, who had given the meeting so much interesting information, and also the Royal Geographical Society, which had kindly lent them a map for illustrating the Professor's remarks.

Professor Bayley Balfour, in thanking the Society for the kind way in which the communication had been received, desired to say that the only way to obtain further information was to impart that which one possessed, and he was much indebted to Mr. Umney and Mr. Moss for what they had said as to the importance of this substance. With regard to aloes, he could not give any very definite information, but he might say that he witnessed the collection of it on the island, which was a very simple process. A small depression was made in the ground, in which was placed a small piece of goat's skin; then a number of aloe leaves were cut off and laid round, with the cut edges projecting into the depression, and in two or three hours the juice had all exuded and filled the little cup thus made. The juice was then transferred to a larger vessel of goat's skin, and in this state was termed *tâyef rhiho*, or watery aloes, and having been kept for a short time, was exported in that state to Mascate and Arabia. He must say that his information on these points, having to be obtained through interpreters, might not be quite accurate in all details. A certain kind of aloes, again, was kept for about a month in skins, during which time the watery part evaporated, and it got into a more viscid consistence and was then known as *tâyef geshushah*, and was exported somewhere else. After it had been kept still longer, say about six weeks from the date of collection, it became quite dense, though not solid, and was then known as *tâyef kasahul*, which was considered the best. He obtained from the Sultan three skins of aloes in different stages, and though he was three weeks on the journey home, he still found the watery aloes quite fluid, and put it into large bottles, in which he found a large yellow deposit at the bottom, possibly consisting of aloin. The other two skins he had left as they were, and on looking at them the other day he found they were quite hard and solid. If the subject was of interest to pharmacists, he should be happy to send specimens for examination. If any members of the Pharmaceutical Society could suggest any way in which these specimens could be utilized he should be only too glad.

The next paper read was on—

The Preparation of Lard.

BY PROFESSOR REDWOOD.

The paper is printed at page 364, and gave rise to the following discussion:—

The President said this was a practical subject, referring to a substance of great importance in pharmacy, and the problem seemed to be whether lard was not best prepared without coming in contact with water.

Mr. Willmott was very glad that his experience of prepared lard, which he communicated to the Conference at Southport, had been the means of eliciting from Professor Redwood the interesting paper he had now given. The method referred to as being adopted by manufacturers of oleomargarine was to an extent identical with what he had advocated, a simple process of melting and straining. There was first the careful selection of the fat, then the separation of the adhering membranes, then the complete bruising up of the mass, and lastly, the melting at the lowest temperature possible and straining through fine tow or a double layer of the finest flannel. He remembered thinking at the time that this was amply sufficient for the purpose intended, but Professor Redwood said filtration seemed desirable where practicable; he presumed filtration through paper was intended, and at the Conference Meeting Professor Attfield referred to a certain separation of material brought about by the filtration of fats. The question seemed to arise, under what conditions was this separation effected, and how did it compare with the process of filtration now proposed. Apart from that point, he thought as regards stability the method given by Professor Redwood was the best which could possibly be adopted. One thing seemed tolerably clear, that the less heat the fat was subjected to, the better, as a rule, was the result.

Mr. Martindale said he had not had much personal experience in this matter, but he had seen the manufacture of lard on a large scale in the North of England some time ago. The process consisted in cutting up the flare and acting upon it by means of steam, so that the scrap which was left behind was rendered almost crisp. The strained melted fat was poured into warm water and stirred, after which a considerable sediment fell to the bottom, consisting of albumen and other substances. The liquid fat was drawn off into bladders at a level above that of the water. That manufacturer supplied very large quantities of very pure lard. Reasoning from analogy one would think that that process still left the lard somewhat hydrated, which he did not think was good, but he knew from experience that it did keep well. That reasoning would lead one to suppose that leaving even a trace of water in contact with fat was bad, that it always tended to cause the fat to become rancid, as it did cod liver oil, for example, and probably if the lard had been thoroughly dehydrated by gentle heat it would have been better. There was something taken out of lard by this process which seemed to be only done by water and which was useful on the manufacturing scale.

The President said it seemed to him that the question lay within a very small compass. He should gather that Mr. Hills, and those who thought with him that water was convenient, reasoned that it was desirable to get rid of a certain unpleasantness which there was about fresh flare, and, instead of leaving the outside to purify itself by exposure to the air for a time, they thought it desirable to wash the internal fat. A good many years ago he had himself made some experiments in that direction, not on a large scale, and the results obtained were pretty much this, that if fresh flare were kept a few hours until it was quite sweet to the smell, then put under an ordinary press and "smashed," and the fat afterwards melted out at the lowest possible temperature, a result was obtained that was all that could be desired. One would naturally suppose that contact with water was not a desirable thing for any fat. He thought the result of Mr. Willmott's paper at the Conference and this one from Professor Redwood would be to suggest a process which would improve the character of this preparation. He concluded by proposing a vote of thanks to Professor Redwood, which was carried unanimously.

Provincial Transactions.

NOTTINGHAM AND NOTTS CHEMISTS' ASSOCIATION.

The opening meeting of the above Association was held at the George Hotel, on Wednesday, October 24. There was a fair attendance of the members present. The President, Mr. Councillor Fitzhugh, F.C.S., occupied the chair.

It was reported that the Pharmaceutical Chemistry Class had begun its meetings at the University College under the superintendence of Professor Clowes, D.Sc., F.I.C. Twenty-seven associates had given in their names. The average attendance had been twenty-three. Several of the masters present testified to the good work the class was doing, and the great amount of assistance it would be to the young men in their preparation for the Minor examination.

The Hon. Secretary, Mr. C. A. Bolton, reported upon the steps the Council had taken towards securing a suitable room for the young men to meet in, and a place where a museum and library might be opened for their use one night per week. Successful arrangements were stated to have been made with the Nottingham School Institute for placing the necessary cases in their rooms at a nominal rental. The meeting cordially ratified the action of the Council, and suggested that the room be fitted up as quickly as possible.

The question of the Society's votes at the coming election of annuitants was next considered, and after discussion of the claims of the various applicants the votes at the disposal of the President were instructed to be divided amongst five specified candidates.

The President announced that since the last meeting Mr. J. H. Atherton, F.C.S., one of the founders of the society and for some years its President, had died. The Council, in the name of the Society, had instructed that a letter of sympathy should be sent to the widow and family, the reply to which had been received, was read, and ordered to be entered on the minutes.

The President then opened a discussion upon Professor Attfield's Presidential Address at Southport, in which he was followed by Messrs. J. Wilford, A. E. Beilby, W. H. Parker, R. Jackson, C. W. Warriner, W. V. Holgate, and others. After a very long and animated discussion, the following resolution on the motion of the Secretary, seconded by Mr. W. H. Parker, was carried unanimously:—"That the best thanks of this Association be given to Professor Attfield, Ph.D., F.R.S., F.I.C., for his able, suggestive and comprehensive address delivered at Southport."

Twenty-two gentlemen were then proposed as associates.

OLDHAM CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

At a meeting of the members of the above Association held in their room, Church Institute, Mr. Charles Jones read a paper on "Botany."

The essayist during his remarks gave a very interesting description of a plant's existence from its seed germination to its maturity, he afterwards spoke of the different functions of each part of the same, and altogether the paper was most enjoyable.

A vote of thanks to Mr. Jones was proposed by Mr. Swinbourn, seconded by Mr. Lees, and passed unanimously. Mr. Martin, President, occupied the chair.

MIDLAND COUNTIES CHEMISTS' ASSOCIATION.

The annual meeting of the above Association was held on Wednesday evening, October 24, last, at 23, Burlington Chambers, New Street, Birmingham, when the following gentlemen were elected officers for the ensuing year:—President, Mr. J. Lucas; Vice-Presidents, Messrs. Brown and Barlow; Hon. Secretaries, Messrs. Thompson and Wright; Hon. Treasurer, Mr. J. Lucas; Auditors, Messrs. Arblaster and Haydon; General Committee, the officers of the Association together with Messrs. Austin, Barclay, Blackwell, Churchill, Dewson, Ellis, Gibson, Grieves, Hooper, Howes, Jones, Morris, Perry, Sanderson, A. Southall, W. Southall, Wakefield, Weaver, Wilcox and Wilkes.

The Secretaries reported that a revised price list with some improvements was in the press and would be ready in a few days; that arrangements had been made with Mr. Stokes Dewson to give a series of lectures for the Minor on two afternoons per week, provided a certain number of students would give in their names at once, and that a hope was entertained that next session, satisfactory arrangements will be made with the authorities of Mason's College to undertake the teaching of pharmaceutical students; that during the past session Mr. David Hooper, F.C.S., gave a very interesting lecture on "Courage," and that the same gentleman would lecture on December 12, next, on "Justus von Liebig: his Life and Works;" and that Mr. A. E. Robinson, F.C.S., had kindly consented to give a lecture on Wednesday, November 28, entitled "Michael Faraday: the Man and the Chemist." The thirteenth annual *soirée* will be held on January 25, 1884.

LIVERPOOL CHEMISTS' ASSOCIATION.

The second general meeting of the thirty-fifth session was held at the Royal Institution, on Thursday evening, October 25. The President, Mr. Edward Davies, F.C.S., F.I.C., in the chair.

The minutes of the previous meeting were read and confirmed, and the following donations were announced:—*The Pharmaceutical Journal*, from the Society; *The Canadian Pharmaceutical Journal*, from the Editor.

Messrs. W. R. Smith and T. R. McPhail were elected members.

There being no miscellaneous communications, the Predent called upon Mr. A. H. Mason, F.C.S., Vice-President, to read the paper of the evening, on the following subject:—"The Condition of Pharmacy: Should it be under State Control?" The paper, which was of considerable length, discussed the points raised in Professor Attfield's address and the subject of patent medicines. With respect to proposed legislation, the author expressed his opinion that the draft Bill to amend the Pharmacy Act did not emanate from a body which was representative of the chemists and druggists of the country.

M. T. F. Abraham said that with regard to the patent medicine duty, he agreed with the author of the paper that the term "patent," as applied to this class of medicines, was an absurdity and anomaly, conveying, as it did, to the public mind the notion that these medicines received the Government's sanction and approval. In opposition to the opinion given by Mr. Mason he considered that the Pharmaceutical Society might be fairly considered as representing the druggists of this country and that those who held aloof from voting for its members thereby gave their tacit acquiescence to the same. He concluded by proposing a vote of thanks to Mr. Mason for his paper.

Dr. Symes, in seconding the vote of thanks, remarked that Mr. Mason's paper was the first the Association had had, for some years past, bearing directly on trade interests, and he was sorry there were not more present to take an interest in what he would call the politics of pharmacy. He considered that a druggist had as good a chance of making a fair living as any other calling, provided, of course, he possessed the ordinary necessary qualifications, without which no one could expect success. He thought that the whole tendency of the recent address of Professor Attfield was to endeavour to secure a monopoly for the English chemist and druggist. He did not know any class of the community who had anything approaching the monopoly thus claimed for the druggist. The medical faculty had quite as important a claim for State protection as the druggists, and yet they did not attempt to secure the monopoly of the sole right of prescribing, so long as those exercising the same did not assume a title to deceive the public.

Mr. Conroy, in supporting the motion, took exception to Mr. Mason's remark that a copy of Professor Attfield's address should be sent to every member of Parliament. He thought this would be of little benefit, as it was a well-known fact that these gentlemen were amongst the principal supporters of the chief opponent of the druggists, namely, the stores. He could not help thinking that chemists had trespassed on other trades as much as anyone else, and therefore they should be the last to complain of others dealing in articles which in no sense could be considered as within their rights to control. He deprecated the idea of too much importance being placed on the replies from country chemists which had been received by Professor Attfield in response to his inquiries, and concluded by supporting the vote of thanks to Mr. Mason.

The President having put the motion, it was carried by acclamation.

SHEFFIELD PHARMACEUTICAL AND CHEMICAL SOCIETY.

A general meeting was held in the Society's Rooms, Market Place, Sheffield, on Wednesday evening, October 31. Mr. Preston, the President, in the chair.

The minutes of the last meeting were read and confirmed, and the donations of the current numbers of the *Pharmaceutical Journal* announced.

The President then called upon Mr. J. M. Furness to read his paper, entitled "Our Allegiance to the Pharmaceutical Society." We regret that the great pressure upon our space prevents the publication of this address *in extenso*, but the following abstract will indicate its character:—

Mr. Furness commenced his paper by saying that the abstention of so large a proportion of qualified persons from joining the Pharmaceutical Society raised the question as to what could be the cause of the estrangement, and whether the Society had failed to justify its existence as a corporate body in carrying out the principles for which it was established. In order to assist in forming a judgment upon these points, he gave a brief sketch of the origin, establishment and progress of the Society, which he said would be sufficient to make it apparent to all but the biassed, that the Society is worthy and demands the allegiance of all practitioners of pharmacy, and that the position of the eleven thousand who do not subscribe to its funds is not an enviable one, seeing that they are willing to receive everything and unwilling to yield anything. Mr. Furness then proceeded as follows:—"The Society exhibits no signs of decay, it displays no lack of zeal, but still shows a healthy vitality and sound vigorous constitution, and is capable of continuing the work of reform, improvement and progression of which it can show such a satisfactory record during the past forty-two years. It has become a publicly recognized and national institution with which no one need feel ashamed of being connected; it has proved beneficial to the public and creditable to ourselves. It has undoubtedly increased the respectability and importance of our calling and conferred social advantages and distinction upon its followers. From its labours have resulted complete registration of all the members of the body, with all its attendant importance and advantages. Local secretaries have been established throughout the country,—to watch its interests,—who are invaluable for gaining information on any given point, or when the whole body requires rousing into action. It has also always endeavoured to promote good feeling and fellowship among its members, and for this purpose has introduced several pleasant annual social gatherings in London to bring the members together; it has encouraged the formation of provincial Associations, such as this, throughout the kingdom, and its leaders promoted the British Pharmaceutical Conference, all of which have tended to many friendships and acquaintances being formed, and men in the same town, often near neighbours, and who never exchanged a friendly greeting, have been brought together and made friendly. A society which has, in such a brief period, accomplished objects like these among its many achievements, is a distinct gain and advantage to every individual practitioner of pharmacy, and, judging it by its own works, the Pharmaceutical Society claims the allegiance of all. It is, therefore, surprising that such apathy exists among the fraternity about joining its ranks, and that there should be only 5500 connected with the Society out of 17,000 entitled to enjoy its privileges and advantages is simply astonishing, and scarcely speaks well in favour of the perception of those members of the trade, who, while content to reap the advantages the Pharmaceutical Society can bring about and dispense, are also content to receive them as benefits dropped from above, or raised from below, as a matter of course, and requiring no recognition from them. The Society works for all in the trade, not simply for its members now, and this want of allegiance places the Council in an invidious position, seeing it has the government of the whole body in its hands, and only receives the support of about one-third of its constituency. Although it is endowed with considerable duties and responsibilities by the Legislature, it is in reality a voluntary Society, and it is a question well worthy of discussion whether allegiance to the Society should be made compulsory in any way, or whether we should wait patiently until the time comes when none are connected with the business, excepting such as have been under the influence and brought into contact with the Pharmaceutical Society by its examinations, when it is almost safe to predict that a different state of things will exist in the bright time that will dawn upon pharmacy if the Society continues its labours in the future as successfully and upon the same lines as in the past."

The President, in inviting discussion, said that Mr. Furness had travelled over a deal of ground in the half hour he had addressed them. There was plenty of matter for discussion, and as he felt some part of the paper was applicable to himself he should think about making amends. The remarks on the Benevolent Fund were specially worthy of notice, and he commended the fund to their favourable consideration.

Mr. Learoyd moved a vote of thanks, confessing, however, that he was disappointed with the paper. He came, he said, expecting to hear something to argue about, but there was nothing beyond what everybody knew and which was indisputable. He would reserve a statement of his views on some of the questions until the next meeting, when he proposed to read a paper.

Mr. N. E. Smith, in seconding the vote of thanks, said he was at variance with Mr. Learoyd. He considered there was plenty of matter for discussion in the paper; he had gained a good deal of information and had formed a much more favourable opinion of the Pharmaceutical Society than he had had before.

Mr. F. A. Dobson supported the motion of a vote of thanks. In his opinion, joining the Society should be made compulsory on all on commencing business; he could see little difference in this respect between themselves and solicitors who had to subscribe yearly to the Incorporated Law Society, and if they did not pay they did not secure registration, but were struck off the rolls. With reference to restrictions on the sale of poisons he thought the schedule ought to be abolished or considerably extended.

Mr. Furness replied to the discussion and thanked the members for their vote of thanks.

The following gentlemen were elected members of the Society:—Messrs. F. A. Dobson, Harrison, W. H. Maxey and H. R. Thatcher.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A meeting of this Society was held on Thursday, Nov 1, Dr. W. H. Perkin, F.R.S., President, in the chair.

The following certificates were read for the first time:—Messrs. C. J. Baker, F. A. Blair, L. Briant, R. Datta, R. G. Durrant, T. Hart, A. E. Harris, W. Irwin, S. Johnson, R. Jackson, H. C. Lee, W. H. Martin, C. E. Potter, B. M. H. Rogers, W. G. Whittam, H. A. Wetzel.

The President announced that no books would be issued from the Library during the present month, in consequence of the preparation of the catalogue; the books can be used for reference as usual.

The Secretary read the following papers—

On the Production of Hydroxylamine from Nitric Acid. By E. Divers.—Lossen, in 1865, prepared this substance by the action of tin and hydrochloric acid on ethyl nitrate. Maumené showed that ammonium nitrate might be substituted for ethyl nitrate. In 1872 the author found that sodium nitrate, and, indeed, nitric acid itself, could be used with excellent results. Since then the author has worked at the subject and his results are given in the present paper. The author gives a detailed account of the action of various metals on nitric acid alone and in the presence of hydrochloric or sulphuric acid. As an example, 58 c.c. of fuming hydrochloric acid were mixed with 5 c.c. of nitric acid (sp. gr. 1·42) and the mixture poured quickly on 35 grams of granulated tin placed in a flask filled with carbon dioxide. The flask was cooled by immersion in water; the ebullition soon ceased, and the solution was then poured off; 21 grams of tin were dissolved. The solution was diluted, the tin removed by sulphuretted hydrogen, etc., and the hydroxylamine in the filtrate determined by decinormal solution of iodine, sodium carbonate being added to keep the solution alkaline. About 4½ grams of nitric acid were thus converted (out of 5 grams) into hydroxylamine. The following is suggested as a good lecture experiment to show the formation of hydroxylamine. Pour some dilute sulphuric acid on zinc and then add a little nitric acid, in half a minute pour off the acid solution, add a large excess of potassium hydrate so as to dissolve the zinc hydrate, and then a very little copper sulphate solution. The characteristic yellow precipitate, proving the presence of hydroxylamine, will appear on stirring. The latter part of the paper contains a rather lengthy discussion on the nature of the reduction of nitric acid. The author gives the following summary of his results. Free nitric acid yields hydroxylamine when treated with tin, zinc, cadmium, magnesium and aluminium. In the presence of hydrochloric or sulphuric acid the quantity (with tin and zinc) may be considerable. Without a second acid only traces of hydroxylamine can be detected. There is no reason to believe that the action of the hydrochloric or sulphuric acid upon the metal is instrumental in forming hydroxylamine. The second acid serves to decompose nitrate as fast as it is produced. In this way (1) it holds the hydroxylamine in a state more stable than the nitrate; (2) it preserves the hydroxylamine from the destructive action of nitrous acid by preventing that formation of this acid which would otherwise result from the reaction between a metal yielding hydroxylamine and its own nitrate; and (3) it determines the reduction of all the nitric acid to hydroxylamine by supplying the hydrogen for reproducing it and so keeping it free to the last. Metals act upon nitric acid in one of two ways, and are accordingly divisible into two classes. One includes the metals, silver, mercury, copper and bismuth, which form nitrite, water and nitrate, but neither ammonia nor hydroxylamine, and do not convert their nitrate to nitrite. These metals decompose nitric acid into hydroxyl and nitroxyl, combining with these radicals to form hydroxide and nitrite, which by secondary reactions become water, nitrous acid and metal nitrate. These metals therefore separate nitrogen from oxygen (hydroxyl) in decomposing nitric acid; they do not in this decomposition separate hydrogen from oxygen, just as they do not do so in any other case. The other class of metals includes tin, zinc, cadmium, magnesium, aluminium, lead, iron, and the alkali metals. These metals form ammonia and generally also hydroxylamine: they do not yield nitrite or nitrous acid with free nitric acid, but they readily form nitrite by acting on their own nitrate. They exercise two actions; one upon the nitric acid, the other upon the hydroxylamine. They act first upon seven molecules of the acid, separating, in the form of hydroxylamine, the hydrogen of six of them by forming nitrate, and leaving the seventh converted into water and hydroxylamine. This action occurs without evident break into successive stages. The second action of these metals is that in which they combine with hydroxylamine to form metal ammonium hydroxide, which decomposes with water into metal hydroxide and ammonia. Nitrites have a constitution indicated by the name nitronates, *i.e.*, they have their metal directly united to their nitrogen. They have the same radical, NO_2, as nitrates have, these being its metal-oxyl compounds.

Professor Debus, while recognizing the great value of the paper as to its experimental work, could not agree with some of the theoretical conclusions; the statement that a metal attached itself directly to nitrogen in a nitrite seemed quite hypothetical.

Dr. Armstrong said there was so much to be learned as to the action of nitric acid that they were as yet hardly in a position to discuss its decompositions. There seemed to be very little doubt that pure nitric acid had no action upon silver, but that some nitrous acid was necessary to start the reaction.

On the Chemistry of Lacquer (Part I). A communication from the Chemical Society of Tokio by K. Yoshida. Japanese lacquer (Urushi) is the milky secretion of *Rhus vernicifera*. The tree is 9–12 feet and resembles the ordinary wax tree. Two varieties of urushi exist, "Kiurushi" and "Seshime urushi." The "Kiurushi" or raw lacquer is the best, being the natural juice which exudes from cuts in the stem; the seshime urushi being prepared by soaking branches and twigs for some months in water. The urushi is usually coloured with lampblack, vermilion, indigo, etc. The pure urushi is a thick, greyish fluid, having a characteristic sweetish odour, sp. gr. 1·0020 at 20° C. When exposed to moist air at 20° in thin layers it rapidly darkens in colour and dries up to a lustrous translucent varnish. Ishimaton, on February 18, 1879, gave some account of this lacquer to the Manchester Philosophical Society, and showed that it contained a resin, a gum, water and a small quantity of residue insoluble in ether, water and alcohol. The author extracted urushi with alcohol and obtained a peculiar acid, urushic acid, and a volatile poisonous substance. Urushic acid, $C_{14}H_{18}O_2$, is a pasty substance, soluble in benzene, etc., which does not dry up when exposed to moist air. The author has studied the action of bromine, strong hydrochloric acid and nitric acid, and has prepared the copper, lead and iron salts. The gum is identical with gum arabic. A mixture of gum and urushic acid does not harden on exposure to the air. The portion insoluble in alcohol and boiling water contains a peculiar nitrogenous substance, but it has, after boiling, no action on urushic acid; if, however, after extracting the urushi with alcohol the residue be treated with cold water, an extract is obtained containing a diastatic matter which effects the hardening of urushi. The author has made experiments as to the hardening of urushi in different gases; he finds that moist air and a temperature of 20°–23°C. are the most favourable conditions. After the hardening the urushic acid is found to be converted into a new substance, oxyurushic acid, $C_{14}H_{18}O_3$, quite insoluble in every substance tried. This body can be formed by the action of strong chromic acid on urushic acid.

The President said that the mode of action of the diastase did not seem very fully explained in the paper; it was curious that the lacquer varnish dried best in moist air, the reverse being the case with the ordinary varnishes in use in this country. In some experiments which he had made with an amber varnish he had found that sunlight had a great influence in promoting the hardening of the varnish.

On some Compounds of Phenols with Amidobases. By G. Dyson.—In a recent paper, Dale and Schorlemmer came to the conclusion that aurin combines with the amidobases, and prepared pure rosanilin phenate. The author has prepared and investigated this and several other similar compounds:—Aniline phenate, toluidine phenate, naphthylamine phenate, aniline β-naphthate, toluidine naphthate, rosaniline phenate, xylidine naphthate, rosaniline aurinate, aniline aurinate.

On the Alleged Decomposition of Phosphorous Anhydride by Sun-Light. By R. Cooper and V. B. Lewis.—In a paper read before the Southport Meeting of the British Association by the Rev. A. Irving, the author states that phosphorous anhydride, prepared by passing a slow stream of dry air over molten phosphorus decomposes when exposed to sunlight into amorphous phosphorus and phosphoric anhydride. The authors have repeated this experiment and analysed the sublimate obtained in the manner described by Irving; it consisted of 78·2 per cent. of phosphoric anhydride, 4·7 per cent, phosphorous anhydride and 17 per cent. of phosphorus. On exposing this white mixture to sunlight it became red, the phosphorus being converted into the amorphous variety. In another experiment the air after passing over the melted phosphorus bubbled through carbon disulphide. After some time the bisulphide was allowed to evaporate on blotting paper, when enough phosphorus was left behind to give dense fumes.

Professor Debus called attention to the fact that it was generally stated in text-books that phosphorous anhydride could be prepared by passing air over heated phosphorus.

The Society then adjourned to November 15.

CHEMISTS' ASSISTANTS' ASSOCIATION.

A meeting of this Association was held on Wednesday evening, October 31; Mr. Parkinson, President, in the chair, when a paper on "New Remedies" was read by Mr. J. F. Burnett, of which the following is an abstract:—

The essayist remarked that what he had to say was not the result of original investigation, but a series of facts compiled from various published sources which might prove interesting, as many pharmacists seemed to know very little of these recently introduced drugs. The drugs alluded to were as follows:—The bark of *Hamamelis virginica*, a remedy gaining a reputation as an astringent and likely to gain a permanent place in materia medica. Sassy bark, recommended by some as sedative in heart disorders, its action being somewhat similar to digitalis. The seeds of *Abrus precatorius*, not only considered interesting on account of the property ascribed to the infusion of producing ophthalmia, but also used as a standard of weight for Indian jewellers. *Piscidia erythrina* a third drug furnished by the Leguminosæ, possessing sedative properties similar to opium, but producing no objectionable after-effects. Kola nuts, very much vaunted now as a specific for intemperance, their property being usually ascribed to the caffeine they contain; their use as a clearing agent for putrid water was alluded to. Quebracho, becoming a favourite with many practitioners as a remedy for dyspnœa. At one time there were numerous substitutions in the market, so that this drug had only recently been fairly tried. A brief allusion was made to cascara sagrada, as being likely to perfectly supersede the other species of *Rhamnus* as a safe but certain laxative. Papaw juice was spoken of as a valuable aid to digestion, its active principle being papain. In conclusion the essayist hoped that what he had said would stimulate all the members of the Association to inquire more into these "new remedies," a further knowledge of which would, of course, make them better qualified for their position in life.

Specimens, sketches, etc., were exhibited to illustrate the paper.

A discussion followed, in which the President, Messrs. Braithwaite, Briggs, Cooper, Cracknell and Millhouse took part.

Parliamentary and Law Proceedings.

Alleged Poisoning by Canned Salmon.

On Thursday, Mr. S. F. Langham, the Deputy Coroner for Westminster, held an inquiry as to the circumstances attending the death of Julia Nunn, aged 17. It appeared from the evidence that the deceased became ill after eating some potted salmon purchased at a grocer's shop.

Dr. John Hunt, surgeon, of 1, St. George's Square, Pimlico, said he was called to see the deceased on Monday afternoon, the 13th ult., when she was in a serious condition, and had all the appearance of a person suffering from an irritant poison. He held a consultation with another medical gentleman, and they agreed that the girl was suffering from the effects of poisoned salmon. Four days later the patient showed symptoms of improvement; but she had a relapse, and died last Saturday morning. He made a *post-mortem* examination and found all the stomach, intestines and other internal organs in a state of extreme inflammation. Death had been caused by peritonitis, the result of taking poisoned salmon. On looking at the pot from which the salmon had been taken he found it to be denuded of its tin in many places. The tin was dissolved from the iron, and nitrate of tin (*sic*) having been formed, the salmon had become decomposed. In his opinion all such tins ought to bear a label to the effect that the food should be eaten directly the tin was opened. Experiments had been made, and the "nitrate of tin" found mixed with the fish had killed guinea pigs. It would be much better if food of this description were put into glass vessels.

The Jury returned a verdict that the deceased was poisoned by tinned salmon imported by Messrs. Lazenby and sold by Mr. Barrow.

The Coroner said he would communicate with Messrs. Lazenby with a view to their corresponding with the manufacturers of the compound.—*Times.*

Poisoning by a Liniment.

On Thursday, Dr. Danford Thomas held an inquest on the body of William Harris, a solicitor, aged 82, who died on Tuesday afternoon. According to the evidence of the son of the deceased, his father, who was very absent-minded, went into his dressing-room on Tuesday morning and took what he believed to be an aperient draught. Shortly afterwards he complained of a pain in his stomach. Dr. Norton was called in and found the deceased's tongue much blistered. The bottle which was supposed to have contained the draught was ascertained to have held a poisonous liniment, known as "nine oils," largely consisting of ammonia, and used by the deceased for skin disease from which he suffered. The deceased had long been in the habit of doctoring himself, and his dressing-room (the Coroner said) presented the "appearance of a chemist's shop in a state of confusion." The liniment was poured by the deceased from a large into smaller bottles for more convenient use.

Dr. Norton said that death was the result of the dose of liniment taken by the deceased.

The Jury returned a verdict of "Death from misadventure."—*Times.*

Reviews.

The Book of Prescriptions.* Sixth Edition. By Henry Beasley.

The various publications bearing the author's name are so well known that they scarcely need introduction. They show uniformly care and accuracy in their compilation; and the favour with which they have been received by the public is evidence that they have supplied a want.

The present volume contains upwards of three thousand prescriptions selected from the practice of the medical profession; the source of each drug is indicated, and brief pharmaceutical notes appended. The solubility, vehicle for exhibition, dose, incompatibles, and when necessary, the antidotes of each remedy are described.

To the young practitioner, therefore, such a compendium offers obvious advantages; while the pharmacist may gather much information from its pages. It is a handy and useful manual.

Workshop Receipts.† Second Series. By Robert Haldane.

The title of the book affords the best indication of its design. We have already important works bearing upon the industrial arts and allied sciences, which under the form of enlarged dictionaries or encyclopædias treat fully on manufacturing processes. The names of Brande, Ure and Muspratt will naturally occur to every reader in connection with this subject. But the growth of technical art has been so rapid, and so many minor interests have been created, that there remains ample room for less ambitious effort, which in its own way may be distinctly useful. There is a large amount of information indispensable to the artizan, the small manufacturer or the scientific amateur, which though scarcely worthy of being included in an elaborate treatise, yet might find a place with great advantage in some special reference work. To group together these outlying processes, and to describe them so that the reader may be able to apply them for himself, is the object contemplated by Mr. Robert Haldane. An opportunity has been offered to the writer, of which he has availed himself successfully, of introducing a number of recipes and hints based rather on the rule of thumb than on scientific principles. These are called generally trade secrets, and are often guarded by their possessors with jealous care. They are the results of long experience and their practical value cannot be ignored. The result is the volume now before us, in which the genuine workman will find many things worthy of his attention, and which the amateur may consult with equal pleasure and instruction. Amongst the more chemical topics will be found alcohol, the alkaloids, disinfectants, hydrogen peroxide and a new process for magnesia; the arts are represented by bleaching, dyeing, inks and pigments; pharmacy, by the preparation of essences, extracts and glycerine; the laboratory, by cements and lutes; while the amateur may turn to the sections of luminous bodies, or copying. Confectionery occupies a fair space, and there are a variety of other receipts belonging to the workshop, but hard to classify. By 'Receipts,' short abstracts are intended or descriptive notices, for the work in no way resembles a pocket formulary, and its contents are so well arranged and elucidated that the term compilation is not strictly accurate. Mr. Haldane has executed his task faithfully and well. A copious index is appended.

* London: J. and A. Churchill. 18mo. Pp. i.–xx., 1–593. 6*s*. 6*d*.

Correspondence.

Liquid Extract of Cinchona.

Sir,—In allusion to the observations of Professor Redwood, reported in your correspondence of November 3 I have no desire to set myself up as a censor of the British Pharmacopœia, nor do I consider that because I intimate that the extractum cinchonæ liquidum has little relation to the liquor cinchonæ cordifoliæ of the late Richard Battley, I can be regarded as condemning it. All I would be taken to mean is, that although it may be a substitute for, it is not the preparation made by Mr. Battley during the time I was working with him in his laboratory, when it acquired its speedy reputation amongst the most distinguished members of the medical profession. The remarks I referred to were made at the meeting in March last, by one who has had great experience in the pharmacy of bark, and I was, accordingly, led to quote them. If Professor Redwood will be so good as to refer, he will see that I did not declare "that the framers of the Pharmacopœia have much aided in bringing the pharmacy of cinchona bark into a muddle," but that following the quotation, which Dr. Redwood has not given in full, I added that they "had much aided this state of things." If Mr. Battley gave, "for the benefit of all comers, a detailed description of his process, and which is precisely that given in the Pharmacopœia," it would have been interesting if Dr. Redwood had put this at the meeting in March, when he stated that the preparation did not originate even with the pharmacists or medical men of this country. If Mr. Battley did, generously, give his form in all its details to the London College, why was the name changed to extractum cinchonæ liquidum, and if also, for the benefit of all comers, why have there been and why are there still so many feeble imitations, and where the occasion for so much debate?

Referring to my remark that I forbear, in justice to another, to recapitulate the steps of the process, Professor Redwood kindly suggests that I might have written, in justice "to myself." Not having the slightest interest, directly or indirectly, in the liquor cinchonæ cordifoliæ, I can dismiss this part of the matter for the Professor to digest.

A dead dog is better than a live lion, and I should wish that Mr. Battley's word for his process should be taken in preference to Heathfield's; yet, although the former truthfully stated facts, he did not disclose the whole of the operations; did not enter into some details of manipulation and elimination which, at least when I worked with him in his laboratory, constituted the essence and completeness of the preparation. I am not the champion of the late Richard Battley, nor of any other maker of his liquor cinchonæ; but it is just to his memory to touch upon the foresight and ability he displayed at a time when pharmaceutical skill was shrouded in the gloom of the dark ages, and to add that he introduced a medicine which rapidly gained general esteem, and which, whatever may have been his public utterances regarding it, has not yet made its appearance in any published formula.

Shortly referring to the inquiry of "D. Cinchon," it is not for me to contribute any expresssion regarding the label. I was not the composer of it, nor have I seen it for upwards of twenty years. The process which was adopted was of such a nature that a product was obtained very much stronger than any other liquid preparation of bark of the same specific gravity with which I have been acquainted, but I must ask your correspondent to refer to another source for a reply to his inquiry.

Wilson Street. W. E. Heathfield.

Ungt. Hydrargyri Nitratis.

Sir,—I am greatly obliged to Mr. Maben for the trouble he has taken in further elucidating his paper relative to the above Pharmacopœia preparation. In referring, in his letter, to my contribution on the ointment bases, he does not, I think, represent me quite correctly. I shall be glad, therefore, without wishing to prolong the discussion, or to encroach needlessly on your space, if you will allow me just a word or two in reply.

Mr. Maben says:—"Mr. Willmott states that olive oil ointments do not deteriorate for the reason that 'a larger proportion of the acid is retained in its normal condition.'" Now I do not "state" this; I simply say it will be convenient to adopt it as an hypothesis; and though I do not, and will not, contradict Mr. Maben's statement that, "as between an olive oil ointment and a seed oil (10 per cent.) ointment, the difference is due not so much to the acid as to some active principle in the seed oil;" it has yet, I think, to be shown that with an equal quantity of nitric acid present in the two cases (both ointments being kept in securely stoppered bottles), there would, in the long run, be much, if any, difference between them. In referring, in my paper, to nitric acid as preventing all change (whether pure oil be used or not), I speak of it as being, not simply "in excess," but as being increased to three-fifths of the weight of the oil and lard combined, a quantity, of course, quite inadmissible in any ordinary formula.

Again, Mr. Maben says:—"Mr. Willmott, referring to lard, states that its reducing power is even lower than that of oil, etc." I cannot find such a statement in my paper. I assume (and here again it is put as hypothetical) that lard exercises less power than even olive oil—not in "reducing" the mercury, but in breaking up the nitric acid in the presence of heat, and hence the more stable result. When the finished ointment is mixed with seven times its weight of lard on an ordinary slab, Mr. Maben will see at once that the conditions are entirely different. Squire, in his 'Companion,' speaking of the correctly prepared B.P. ointment, says:—"On being diluted with lard, it soon acquires a leaden colour." In such a case the addition of nitric acid as suggested by Mr. Maben, would scarcely, I think, be considered admissible.

As regards the highest frothing point, it must not be overlooked that my experiments were conducted in the height of summer, and consequently with materials subjected to, or, so to speak, under the influence of a steady July temperature. I can quite believe that a difference of several degrees may be accounted for in this way.

If I were to suggest any alteration in the present formula for ung. hyd. nit., it would be to take the proportions, pretty nearly, of oil and lard of the London Pharmacopœia with the increased quantity of nitric acid ordered in the British. When carefully manipulated, this produces a result satisfactory in all respects.

King's College Hospital. W. Willmott.

The Indication of Alkalinity in the Estimation of Hydrocyanic Acid.

Sir,—In my note on the estimation of hydrocyanic acid, the following clause is slightly in error—(paragraph 3): "No change occurs until the acid is wholly converted into sodium cyanide and the solution has become slightly alkaline, at which point a pale crimson colour appears." Owing to the presence of a little carbonate in the soda solution and the slow action of the acid thereon, the solution becomes slightly tinted before the acid is saturated; the alkali should therefore be added until the solution becomes decidedly crimson. With deficiency of alkali the colour disappears during titration.

A few trials will furnish an indication for future guidance.

Edinburgh. Peter MacEwan.

Tincture of Nux Vomica prepared from the Extract.

Sir,—I have been in the habit of making this tincture from the B.P. extract for about ten years, and unlike Mr. Tanner (vide *Pharm. Journ.*, October 13,) I have every reason to believe it a satisfactory mode of preparing the tincture, and for uniformity of strength far preferable to the B.P. formula, as tinctures made from extract cannot vary so much as when prepared from the crude drug.

Last week I made a quantity of the tincture by putting 48 grs. of extract into a 16-ounce bottle of spirit at 10 p.m., allowing it to stand until next morning, then shaking well, placing it aside for a couple of days, when the tincture had become quite clear and bright, with a slight sediment at the bottom of the bottle, which if collected might weigh about 2 grains. I have always considered this sediment the result of carelessly drying the extract, and I do not think such a small matter as this sediment should outweigh the more important point of uniformity of strength; the B.P. formula is so troublesome that few retail chemists make their own tinct. nux vom.

London. J. Hick.

The Supply of Drugs to the Public.

Sir,—I do not consider that the means proposed by Mr. George Nind to alleviate the unsatisfactory condition of supply and remuneration in the drug trade would prove at all satisfactory. In fact it is scarcely intelligible what he really means.

He commences with a suggestion having, he says, for its object "the bringing back the sale of medicines to the public to its legitimate distributors." Yet he proposes that these distributors should be anyone, grocer, oilman, huckster, store-keeper or draper, for surely he could not look upon the chemist, who merely examined the drugs and supplied the labels, as a distributor.

This may be, as he says, "a simple and easy manner of defining the responsibility of the chemist." But what chemist would like to undertake the responsibility? After examining a parcel of drugs what guarantee would the chemist have that the huckster really put that same drug into the packet that would eventually bear his (the chemist's) name? Then again, Mr. Nind mystifies us by his reference to the Parcels Post. If, as he says, "the sale of medicines is becoming more and more convenient if supplied in packets or bottles" (through the Parcels Post), why could not the sale be confined to chemists, instead of being conducted, as he advocates, by hucksters, etc.

I think too, that if, as Professor Attfield suggests, the spirit and letter of the existing Pharmacy Act were extended, the retail sale in open shop of most of the simple and compound medicines of the B.P. being carried on only by qualified druggists, unregistered persons being allowed to sell the few remaining drugs, if contained in duly secured packets bearing the name of a registered chemist, the condition of supply in the drug trade would be more satisfactory, and the remuneration also, the latter I think being greater than if the chemist examined drugs for hucksters and supplied them with labels. J. Kemble.

F. Barry.—We are unable to give you any information as to the comparative rarity of the two works, which are both in the library of the Pharmaceutical Society. The price that they would fetch would depend very much upon the idiosyncrasy of the buyer.

C. Ridgley.—The penal provisions are very sweeping in their character. According to 52 Geo. III. c. 150, sect. ii., any person who "shall utter, vend, or expose to sale, or offer or keep ready for sale, whether for foreign or home consumption, or buy or receive or keep for the purpose of selling by retail either on his, her or their own account, or on account or behalf of any other person or persons, any packet," etc., containing an article liable to pay duty as a patent medicine, which is not provided with the proper stamp, is made liable to forfeit for every offence the sum of £10.

J. H. H.—For information respecting "kairine," see vol. xiii., pp. 444, 994 and 1065.

Pharmakon (who should have sent his name and address) is recommended to apply to one of the nursing associations for information.

Communications, Letters, etc., have been received from Messrs. Pridham, Stanford, Gostling, Mayor, Wood, Moeller, Kenbaan, Kino, T. A. W.

OLEUM RUSCI.*

BY PETER MACEWAN.

During the past two or three years a demand has sprung up for oleum rusci, and considerable doubt has been expressed as to its nature and quality, articles of different characters having been supplied.

It would appear from the name that the article has some relation to butcher's broom (*Ruscus aculeatus*), but we learn from various sources that it is merely one of the synonyms of the empyreumatic oil of common birch (*Betula alba*). Thus the Danish Pharmacopœia, 1805, has the oil under these names, "Oleum betulinum, oleum rusci, oleum brusci," the latter being another name for the butcher's broom. These names are quoted in the Norwegian Pharmacopœia of 1854 under "Pix epidermidis betulæ albæ;" more recently we find that Hager uses the synonym for the birch tar oil, and the Dutch Society for the Advancement of Pharmacy have it as "Oleum betulæ rectificatum, oleum rusci."†

I can find no explanation of the association of the words "Ruscus" and "Bruscus" with this birch product, and can offer none, unless "Brzoza" (Polish for birch) may have been corrupted into "Bruscus" and thence into "Ruscus." At all events it is beyond dispute that oleum rusci is birch tar oil.

The oil has been long known as that used in currying Russia leather, to which it imparts the peculiar odour and lasting properties that are so much admired; it is chiefly made in Russia and Poland. The bark, and sometimes the rootlets and twigs, are subjected to dry distillation, the retort being of clay and connected by wooden pipes to a receiver placed in the earth. Hager states that this oil is a thickish liquid of a reddish-brown or brown-black colour, peculiar empyreumatic odour, and sparingly soluble in water, but soluble in alcohol and ether to a great extent. The redistilled oil of the Dutch Society is said to be a red-brown volatile oil, sp. gr. 0·800–0·987, soluble in an equal weight of alcohol and imparting an acid reaction to water. Birch bark has a mildly fragrant odour and by gentle heating yields a sublimate of birch camphor or betulin ($C_{36}H_{60}O_3$). This body, as obtained from the bark by exhaustion with alcohol, is odourless and tasteless, but when subjected to a high temperature (above 258° C.) it gives off vapours smelling strongly like Russia leather. This change will very probably be effected in the distillation of the empyreumatic oil from the bark, thereby accounting for its distinctive odour. Independently of its use in currying, the oil is held in high esteem by the Russian peasantry as a household remedy for all diseases, as well as by the medical practitioners in the treatment of skin diseases, rheumatism and the like; it is similarly used in Germany, whence it is exported. Its reputation has travelled to this country, but I am afraid that the remedy has not accompanied the reputation.

Through the kindness of Mr. Holmes, Curator of the Museum of the Pharmaceeutical Society, I have received a small portion of a veritable specimen brought from Russia by Mr. Greenish, of which Mr. Holmes gives me the following particulars:—

"Specimen 511 b" (Museum Catalogue) "is a black empyreumatic fluid, resembling in odour the liquid known as 'essence of smoke,' used for curing hams; after a mere trace of it has been rubbed on the hand an odour like Russia leather is perceptible. The fluid, when caused to cover the side of the bottle in thin layer, is black with a brown tinge. . . . I believe the pyroligneous oil of birch is sometimes prescribed under the name of 'ol. rusci.' . . . . Dr. Symes tells me that there is a brown oil of birch which he believes is only the dark oil redistilled." There is no doubt whatever that oil similar to Mr. Greenish's is extremely rare in this country, although the oil mentioned by Dr. Symes is readily procurable; but there are others which can only be called substitutions and sophistications, and of these I append particulars. I have only had small samples given me, and of these only No. 1 seems favourable for further investigation.

No. 1. Red-brown "redistilled oil," sp. gr. 0·941. Exposed for fifteen minutes on a water-bath it was reduced to half its original bulk. Residue resembled Mr. Greenish's specimen; betulin odour intensified, but more pyroligneous than the veritable specimen.

No. 2. Red-brown "redistilled oil," sp. gr. 876. (This oil is more fragrant than the genuine or No. 1, and suggests "doctoring.") On a water-bath, the greater part volatilized within ten minutes, leaving a small residue of an oily nature and strong pyroligneous odour.

No. 3. A thick tar, black and bituminous. Odour somewhat like huile de cade. This was not examined, Hager stating that very thick varieties should be rejected.

No. 4. An amber coloured oil, sp. gr. 0·891. Odour like that of common spirit of tar (ol. picis rect.). On the water-bath a small quantity was vaporized within ten minutes, leaving a mere trace of resinous matter destitute of betulin odour.

Owing to my portion of Mr. Greenish's sample being extremely small, I have only been able to take its sp. gr. roughly and found it to be 0·943: this, however, requires verification. On the water-bath it leaves a thick and tenacious black residue having the betulin odour. The only specimen which compares favourably with it is No. 1, which answers the description of the redistilled oil of the Dutch Society. It is much thinner than the genuine oil and the pyroligneous odour is stronger; but a trace of it, treated as directed by Mr. Holmes, gives a powerful betulin odour in the course of fifteen minutes. This variety is readily obtainable. From the behaviour of No. 2 I am inclined to think that it is a "made-up" oil, since the fragrance entirely disappears on the water-bath. No. 4 is the "ol. rusci" which has been so largely supplied to pharmacists, and several eminent dermatologists have formed their opinions of the value of the remedy from their experience with this variety. It is not surprising, therefore, that they have reverted in some cases to old-fashioned remedies such as huile de cade. This is to be regretted, for ol. rusci has been found useful in the hands of continental practitioners, and if a demand were here made for the genuine oil, means would not be wanting for obtaining it.

I cannot conclude without expressing my thanks to Mr. Holmes for his assistance, and to Messrs. Crowden and Hill for specimens.

* The greater portion of this paper was read before the Edinburgh Chemists' Assistants and Apprentices' Association, November 7, 1883.

† *Pharm. Journ.*, [3], xiii., 10.

THE NEW PHARMACOPŒIAS FOR THE UNITED STATES AND GERMANY.

(*Continued from p.* 342.)

SODIUM SALTS.—The total number of kinds of sodium salts included in the U.S.P., 1870 and 1880, the P.G., 1870 and 1880, and the B.P. is 27, and of these 24 are in the U.S.P. 1880. None has been omitted that was in the U.S.P., 1870, whilst on the other hand 9 have been added,—the benzoate, bisulphite, bromide, chlorate, iodide, pyrophosphate, salicylate, santoninate and sulphocarbolate. In fact there is really only one sodium salt in the other Pharmacopœias that is not in the U.S.P., 1880,—the valerianate of the B.P.; the other two kinds not included being natrium carbonicum crudum and natrium sulfuricum siccum, P.G. The P.G., 1880, includes only 16 kinds of sodium compounds: the hyposulphite, pyrophosphate and santonate of the P.G., 1870, having been omitted and the benzoate, bromide, iodide and salicylate added. It will, therefore, be seen that two out of the three that have been dismissed from the P.G., the pyrophosphate and santoninate, have now been included in the U.S.P., presumably to meet the requirements of medical practitioners of German origin in the United States, whilst the hyposulphite was official before. The following are principal characters of the sodium compounds in the U.S.P. or P.G., but not in the B.P.:—

Sodii Benzoas, U.S.P.; *Natrium Benzoicum*, P.G. —According to the U.S.P., the benzoate of sodium contains a molecule of water of crystallization, and is "a white semi-crystalline or amorphous powder, efflorescent on exposure to air, odourless or having a faint odour of benzoin, of a sweetly astringent taste free from bitterness and having a neutral reaction." In the P.G. it is said to be a white, anhydrous, amorphous powder, which in aqueous solution (1 in 10) has a subacid reaction. The U.S.P. gives the solubility at 15° C. as 1 in 1·8 of water and 1 in 45 of alcohol; in boiling water 1 in 1·3 and in boiling alcohol 1 in 20. When heated it melts, emitting vapour having the odour of benzoic acid, then chars and finally leaves a blackened residue having an alkaline reaction, which effervesces with acids and imparts a yellow colour to flame, not more than transiently red when observed through blue glass. An aqueous solution treated with dilute solution of ferric sulphate gives a flesh-coloured precipitate, which distinguishes it from sodium salicylate. The P.G. adds tests for the absence of carbonate, sulphate or chloride, and requires that the pasty crystalline mass that forms when an aqueous solution (1 in 12) is treated with hydrochloric acid shall be soluble entirely in ether.

Sodii Bicarbonas Venalis, U.S.P.—The U.S.P. admits a commercial salt, which according to the tests must correspond to at least 95 per cent. of bicarbonate of sodium.

Sodii Bisulphis ($NaHSO_3$), U.S.P. (new).—Opaque, prismatic crystals, or a crystalline or granular powder, slowly oxidized and losing sulphurous acid on exposure to air, having a faint sulphurous odour, a disagreeable sulphurous taste and an acid reaction. Soluble in 4 parts of water or 72 parts of alcohol at 15° C., in 2 parts of boiling water and in 49 parts of boiling alcohol. The iodine and starch test indicates at least 90 per cent. of pure bisulphite of sodium. Bisulphite of sodium is distinguished from the hyposulphite by the aqueous solution evolving sulphurous vapour and not becoming cloudy upon the addition of hydrochloric acid. It is not so stable as the sulphite and requires to be kept in stoppered bottles.

Sodii Bromidum, U.S.P. (new); *Natrium bromatum*, P.G. (new).—According to the U.S.P. in "small colourless or white monoclinic crystals, or a crystalline powder, permanent in dry air, odourless, having a saline, slightly bitter taste and a neutral or faintly alkaline reaction. Soluble in 1·2 parts of water or 13 parts of alcohol [sp. gr. 0·820] at 15° C.; in 0·5 part of boiling water or in 11 parts of boiling alcohol." The P.G. differs in giving the solubility as in 1·8 parts of water or in 5 parts of spirit (sp. gr. 0·830). Bromide of sodium crystallizes at ordinary temperatures in rhombic prisms with two molecules of water, but at a temperature above 30° C. it crystallizes anhydrous; it is this anhydrous form that is official in both works. Tests for the absence of bromate, iodide and more than a trace of sulphate or potassium salt are given. The U.S.P. test for chloride would allow 3 per cent., but that of the P.G. only 2¼ per cent. The P.G. also requires that when placed upon moistened red test paper bromide of sodium shall not immediately produce a blue colour.

Sodii Chloras, U.S.P. (new).—"Colourless, transparent tetrahedrons of the regular system, permanent in dry air, odourless, having a cooling saline taste and a neutral reaction." It has the advantage of being much more soluble than the corresponding potassium salt, dissolving in 1·1 parts of water or 40 parts of alcohol at 15° C.; in 0·5 part of boiling water and in 43 parts of boiling alcohol. When heated the salt melts and afterwards gives off a portion of its oxygen, finally leaving a neutral residue completely soluble in water. Tests are given for the absence of potassium, calcium, sulphate and more than traces of chloride. Chlorate of sodium requires to be kept in well-stoppered bottles and should not be triturated with readily oxidizable substances. It may be as well perhaps to repeat the caution that "natrium chloratum, P.G." is chloride of sodium.

Sodii Hyposulphis ($Na_2SO_3 \cdot 5\,H_2O$), U.S.P.—"Large colourless transparent monoclinic prisms or plates, efflorescent in dry air, odourless, having a cooling, somewhat bitter and sulphurous taste and a neutral or faintly alkaline reaction." Soluble in 1·5 parts of water at 15° C.; or, with partial decomposition, in 0·5 part of boiling water; insoluble in alcohol. When rapidly heated to about 50° C. the crystals melt; when slowly heated until they have effloresced and afterwards to 100° C. they lose all water (36·3 per cent.), and at a low red heat the salt is decomposed. The aqueous solution dissolves chloride or oxide of silver and discharges the colour of solution of iodized starch or of solution of iodine. The hyposulphite of sodium is distinguished from the bisulphite and sulphite by the aqueous solution when treated with sulphuric acid evolving the odour of burning sulphur and giving a white precipitate. Tests are given for the absence of sulphate or carbonate. This salt has been omitted from the P.G.

Sodii Iodidum, U.S.P. (new); *Natrium Iodatum*, P.G.—The U.S.P. describes iodide of soda as occurring "in minute colourless or white monoclinic crystals, or a crystalline powder, deliquescent on exposure to air, odourless, having a saline and slightly bitter taste and neutral or faintly alkaline reaction." The P.G. simply says; "pulvis siccus, albus, crystallinus, aëre humescens." Both these descriptions would exclude the crystalline tables obtained by crystallizing the salt at the ordinary temperature, as these contain one-fifth (2 molecules) of their weight of water and effloresce in dry air. The U.S.P. gives the solubility as in 0·6 part of water, or in 1·8 parts of alcohol at 15° C.; in 0·3 part of boiling water. The P.G. says it is soluble in 0·9 part of water or 3 parts of spirit at 15° C. Tests are given for the absence of iodate and the limits of bromide, chloride and sulphate.

Sodii Pyrophosphas ($Na_4P_2O_7 \cdot 10H_2O$), U.S.P.—This is another salt that has been omitted from the P.G. simultaneously with its introduction into the U.S.P., where it is required in consequence of a modification of the process for pyrophosphate of iron. It is described as in "colourless, translucent, monoclinic crystals, permanent in the air, odourless, having a cooling, saline and feebly alkaline taste and a slightly alkaline reaction." Soluble in 12 parts of water at 15° C., or 1·1 parts of boiling water; insoluble in alcohol. When heated it loses its water of crystallization, and then fuses, and upon again cooling forms a crystalline mass. Its aqueous solution gives with excess of solution of nitrate of silver a white precipitate and a neutral filtrate.

Sodii Salicylas ($2NaC_7H_5O_3 \cdot H_2O$), U.S.P. (new); *Natrium Salicylicum*, P.G. (new).—The U.S.P. describes this important salt as in "small white crystalline plates, or a crystalline powder, permanent in the air, odourless, having a sweetish saline and mildly alkaline taste and a feebly acid reaction." Soluble in 1·5 parts of water or 6 parts of alcohol at 15° C.; very soluble in boiling water and in boiling alcohol. The P.G. defines it as in white crystalline anhydrous scales, having a sweet saline taste and soluble in 0·9 part of water or in 6 parts of spirit at 15° C. The other characters are practically the same in both works. When heated the salt gives off inflammable vapours and leaves 30 to 31 per cent. of an alkaline residue that effervesces with acids. Perchloride of iron added to an aqueous concentrated solution produces a red-brown and to a dilute one a violet colour. Sulphuric or hydrochloric acid produces in an aqueous solution a white precipitate that is soluble in ether. Freedom from organic matter is indicated by it remaining free from colour when shaken with 15 parts of sulphuric acid. Tests are also given for the absence of carbonate, chloride and sulphate.

Sodii Santoninas ($2NaC_{15}H_{19}O_4 \cdot 7H_2O$), U.S.P. (new).—The introduction into the U.S.P. of santoninate of soda also has been simultaneous with its dismissal from the P.G. It is described as in colourless, transparent, tabular, rhombic crystals, slowly coloured yellow by exposure to light, slightly efflorescent in dry air, odourless, having a mildly saline and somewhat bitter taste and a slightly alkaline reaction. Soluble in 3 parts of water or 12 parts of alcohol at 15° C., and in 0·5 part of boiling water or 3·4 parts of boiling alcohol. At 100° C. it loses its water of crystallization (18 per cent.), and at a higher temperature chars and finally leaves an alkaline residue. Hydrochloric acid produces in an aqueous solution a crystalline precipitate which is soluble in chloroform and gives with alcoholic solution of potash a scarlet liquid that gradually becomes colourless.

Sodii Sulphis ($NaSO_3 \cdot 7H_2O$), U.S.P.—"Colourless, transparent monoclinic prisms, efflorescent in dry air, odourless, having a cooling saline and sulphurous taste and a neutral or feebly alkaline reaction." Soluble in 4 parts of water at 15° and in 0·9 part of boiling water; sparingly soluble in alcohol. When gently heated it melts and loses its water (50 per cent.) and at a red heat is decomposed, leaving an alkaline residue. Hydrochloric acid added to an aqueous solution gives rise to the odour of burning sulphur, but the solution does not become cloudy, which distinguishes this salt from the hyposulphite. The iodine and starch test corresponds to 90 per cent. of pure sulphite of sodium.

Natrium Sulfuricum Siccum, P.G.—Besides the ordinary hydrated sulphate of sodium the P.G. includes a dried salt, and it is this that has to be used whenever "natrium sulfuricum" is ordered in powders in a German prescription. It is prepared by exposing the coarsely powdered sulphate to a temperature not exceeding 25° C. until it has become completely pulverulent and then drying it at 40° to 50° C. until it has lost half its original weight.

Sodii Sulphocarbolas ($NaC_6H_5SO_4 \cdot 2H_2O$), U.S.P. (new).—"Colourless transparent rhombic prisms, permanent in the air, odourless or nearly so, having a cooling, somewhat bitter taste and a neutral reaction." Soluble in 5 parts of water or 132 parts of alcohol at 15° C.; in 0·7 part of boiling water and in 10 parts of boiling alcohol. When heated the salt loses its water and forms a white powder; then emits inflammable vapour having an odour of carbolic acid and leaves a residue weighing 36 per cent. of the original weight, a filtered solution of which, acidulated with nitric acid gives a white precipitate with solution of chloride of barium. A dilute aqueous solution of the sulphocarbolate is coloured violet by a 10 per cent. solution of ferric chloride.

(*To be continued.*)

KAIRINE AND KAIROLINE: NEW ANTIPYRETICS.*

BY PROFESSOR FILEHNE.

The first named of these bodies, an alkaloid lately built up synthetically by Dr. Otto Fischer, lecturer on chemistry in the University of Munich, seems to be one of the most important of the recent additions to the materia medica. It appears to be really an ideal antipyretic, controlling febrile temperatures without injuriously affecting the system in any way; its action is directed solely to the lessening of the production of heat.

Its chemical origin is interesting. Quinine, as is well known, is a derivative of chinoline, a circumstance which led to the employment of the latter as a substitute for the former. The large proportion of hydrogen present in quinine, together with the results of certain recent investigations, have led chemists to regard the quinine molecule not as based on chinoline simply, but on a *hydrated* chinoline. Starting, therefore, from hydrated chinoline, Drs. Fischer and Konigs endeavoured to obtain, by synthetical means, other bodies having the antithermic properties of quinine. By hydration and oxidation processes, by the addition of methyl or methoxyl groups to the hydrated chinoline molecule, these gentlemen have succeeded in forming an extensive series of bodies, and their experiments are still directed to the same object. These bodies have been handed over to Prof. Filehne for examination; and thus, since the beginning of 1881, have investigations been going on to determine the directions in which are to be sought chinoline derivatives having the desired antithermic properties. These long sought for bodies, having no local action, but having the power of reducing the temperature to the normal

* *Berl. Klin. Wochenscher.*, No. 45, 1882. Reprinted from the *Glasgow Medical Journal*, October, 1883.

point, seem to have been found in those hydrated chinoline derivatives whose N-atom, besides its connection with two atoms of carbon in the chinolin formula, is united to the carbon of a methyl group or of another alcohol radical. One of these bodies is the oxychinolinmethyl-hydride of Fischer, named shortly *kairine.* Its formula is $C_{10}H_{13}NO$, that of chinolin being C_9H_7N.

When it had been recognized that the essential element in the process was the addition of methyl to the N-atom in the hydrated chinoline, the chinolinmethyl-hydride (*kairoline*) of Konigs and Hoffmann, and the chinolinethyl-hydride of Wischnegradsky, were tried and also found to have antipyretic properties. Kairoline is built up in precisely the same way as kairine, except that one atom of H is replaced by HO. As the preparation in a pure state of both of these last mentioned substances is costly, as they are volatile and have an unpleasant taste, they have not been so much or so fully tried as kairine.

The *hydrochlorate of kairine* is a clear, crystalline, greyish-yellow powder, readily soluble in water, and having a salt-bitter or somewhat aromatic taste. To some its taste is pleasant; to others it is very unpleasant, necessitating the administration of the powder in wafers. Water should be drunk freely after the powder, especially if the drug is not absolutely pure. This substance has been tried in a series of acute and chronic febrile diseases (typhoid fever, acute articular rheumatism, septicæmia, tuberculosis, acute pneumonia), and in all its antithermic action was found to be constant.

As regards dose, it is stated that in *healthy* adults doses of 1–1·5 gram have no physiological action and no effect on the temperature; further, they produce no unpleasant effects, such as headache, ringing in the ears, sickness, etc. In adult patients, or in debilitated subjects, the dose of 1 gram every two hours is not to be exceeded, otherwise a certain degree of cyanosis is apt to occur. In adult fever cases the most suitable dose is 0·3–0·5 gram every hour or hour and a half. The interval between doses of 1 gram should not exceed two and a half hours; between doses of 0·5 gram it should never be more than one and a half or two hours. To obtain a less pronounced effect the doses should be rereduced, not the interval. The effect of a 1 gram dose lasts no longer than three hours, that of 0·5 gram not longer than two and a quarter hours; and when the influence of the drug is exhausted the temperature again rises, with a feeling of chilliness amounting sometimes to actual rigour. A dose of less than 0·3 gram, given at once, has practically no effect on the temperature. A dose of 0·3 to 0·5, or 1 gram, lowers the temperature distinctly, by ½ to 2° C.; if another dose be given before the action of the former dose is over the temperature falls still farther; and if the dose be increased to 0·5 gram hourly it invariably follows, and without any injurious effect, that after the fourth dose, sometimes after the third, or even second, the temperature falls to the normal point, or even below it. Lower than 37°–36·5° C. (98·6°–97·7° F.), the temperature cannot be brought, even by continuing the administration of the medicine energetically. The action of the drug begins about twenty-five minutes after the dose of 0·5–1 gram is taken by the mouth; its action by hypodermic or rectal injections was not tried. The fall in temperature is more rapid the larger the dose. It is always accompanied by profuse sweating, and this lasts only so long as the temperature continues to fall, and no longer. When the temperature becomes normal or sub-normal, or when it has reached its lowest point in the individual case (it is possible, for example, by means of small doses frequently repeated, to bring the temperature, say from 40° C. to a constant level of 39° or 38·5° C.), that is usually after 2–4 doses have been given, the sweating ceases, and the temperature remains at its new level without further sweating—so long, of course, as the administration of the kairine is continued. These facts and the absence of sweating when the drug is given to healthy individuals, show that the fall in temperature is not secondary to the sweating, but that the latter occurs because the organism, so influenced by the action of the medicine as to demand a lower temperature, endeavours to free itself from the febrile excess of heat by a "critical" sweat; as soon, therefore. as the required temperature is reached the sweating ceases. Even during the continuance of the sweating, but especially after this has ceased and the effects of the lowered temperature are manifest, the patients feel much more comfortable; this is especially the case in croupous pneumonia. A lower temperature, a pulse normal in rate and stronger, slower respiration, diminution of the pain in the side—these are all circumstances which give to pneumonia patients the feeling as of immense improvement in their condition. As soon as the medicine is withdrawn, that is, two to three and a half hours after the last dose (according to the amount taken each time), the old order of things is resumed; shivering occurs, and the temperature rises to the point corresponding to the acuteness of the disease. Nevertheless, in cases of pneumonia (which can be kept quite free of fever throughout their whole course), it was noticed that if they were methodically treated with kairine for fifteen to twenty-four hours the influence of the drug was to some extent maintained even after its withdrawal. Further observations must show whether kairine has a specific action in pneumonia. During the use of kairine (and also of the other two bodies mentioned), the urine becomes dark green, but contains no sugar or albumen.

One disagreeable point in this treatment is that the medicine must be given so often, every two and a half hours at least, if we wish to anticipate shivering and rise of temperature; this disturbs the night's rest. This drawback may be entirely overcome by the administration of a full dose (1·5–2 grams) of *kairoline* the last thing at night; this keeps the temperature down for six hours, and the subsequent rise is gradual and without rigour. Before resorting to this method, however, various alterations and modifications of the administration of kairine should be tried to lessen the above-mentioned drawback. Thus, the rigour and rise of temperature may be brought to that period of the day when remission of temperature might naturally be expected if the case were not under antipyretic treatment, as the lower the point to which the temperatnre has to rise the milder the rigour; accordingly, medication may be suspended about midnight. Or, by gradual lessening of the evening doses the temperature may be allowed to rise gradually; thus, at eight p.m. 0·5 gram, and at nine, ten, eleven, and twelve, 0·25 gram; then the smaller the ultimate rise the less marked the shivering.

It is suggested that kairine might prove an excellent remedy in malarial affections, by giving a dose of 1 gram hourly for three hours before the expected attacks.

The other two bodies (kairoline and chinolinethylhydride) are identical in action. Single doses, such as would prove operative if kairine were used (0·3–1 gram), have no effect, nor has a dose of 0·5 gram hourly. But a dose of 1·5–2 grams produces decided effect, more slowly developed, but lasting about six hours. Sweating is less marked than with kairine; shivering on subsequent rise in temperature is absent or very slightly felt. Urine coloured the same as by kairine. The importance of these drugs for evening administration is obvious; but they are rarely pure, deliquescent, and very unpleasant in taste.

The difference in the action of kairine and kairoline may be accounted for in this way. According to chemical experience, all hydroxyl derivatives, not only of chinoline, but also of benzol, are more oxidizable than the corresponding bodies free of oxygen. Thus the quicker and slighter action of kairine, a hydroxyl body, may be explained, as the whole quantity taken comes into operation on the system immediately. On the other hand, it is conceivable that it is more quickly used up than the more resistent kairoline, which yields only gradually to the oxidizing influences of the organism.

THE POSOLOGY OF NEW REMEDIES.

AN unusual amount of attention has been directed during the past few days to an article which appeared in the *Lancet* for the 3rd inst., bearing the names of Dr. SYDNEY RINGER and Dr. WILLIAM MURRELL, and entitled "Nitrite of Sodium as a Toxic Agent." Although we do not intend to take any part in the discussion that has been raised respecting this paper, believing that the merits or demerits of its form and substance are such as can be best and most fittingly adjudicated upon by members of the medical profession and are certainly unsuited for criticism in the columns of the daily newspapers, nevertheless, we think that sufficient interest has been excited to warrant our giving in these columns a brief *résumé* of the facts, especially since this will furnish an opportunity for referring to an allied subject which we think might at the present time be pressed home with advantage upon the attention of our readers. Drs. RINGER and MURRELL open their paper with the statement that nitrite of sodium, which has recently come more generally into use as a medicinal agent through having been recommended as a remedy for epilepsy, angina pectoris and other diseases of a nervous origin, is now supplied more pure than formerly, and that since nitrate of sodium, with which it was formerly contaminated, is a much less active drug, the administration of the pure nitrite of sodium in doses in which the impure form was formerly administered might produce disastrous results. Indeed recent experiments have satisfied them that pure nitrite of sodium is an active toxic agent, and as an indication of its activity and the symptoms it is capable of producing they publish for the benefit of the medical profession the observations made by them. The earlier experiments were made upon frogs and cats and proved the nitrite to be extremely potent, the injection of four c.c. of a ten per cent. aqueous solution under the skin of two cats, weighing respectively five and a half and six and a quarter pounds,—or about one grain to the pound,—being followed quickly by death with symptoms analogous to those manifested in poisoning by nitrite of amyl. The observations were then extended to human patients, eighteen adults having been ordered ten grains of the nitrite in an ounce of water, while sixteen others were ordered it in five grain doses. Without entering into details as to the exact symptoms, it will suffice to state here that the effects produced on the patients were in the words of the reporters, "not altogether satisfactory." With respect to the first eighteen it is said: "They came back protesting "loudly and required no questioning as to the symp- "toms. They seemed to be pretty unanimous on one point—that it was about the worst medicine "they had ever taken. They said that if ever they "took another dose they would expect to drop down "dead and it would serve them right." The symptoms complained of by the sixteen patients who took five grain doses "were those experienced with the larger dose," though presumably of less intensity. After this, thirteen patients were ordered three grain doses, but in only four of these cases was any complaint made.

It is this record of results that has been made the subject of hostile criticism. The subject was broached in a letter that appeared in the *Standard* of the 9th inst. from a Mr. BELL, who assumed that the experiments had been all made upon hospital patients, apparently without more acquiescence from the subjects in the later series than from those in the earlier, and vigorously denounced "the present increasing "mania for testing anything and everything on all "sorts of animals." This letter was the occasion of an editorial article in the same journal, which contained the same assumptions, but was more temperately written. One of these assumptions has however since been disposed of by the denial from the deans of University College and Wesminster Hospitals that any of the experiments were made upon patients in either of those two institutions. Further, Dr. MURRELL, in a letter, has pointed out that the dose administered was only half the quantity recommended by previous writers, and stated that it was only subsequently to the experiments that it was discovered how the question of dose might be affected by the fact that the nitrite of sodium in ordinary use was impure. The paper will probably be the subject of further explanation and discussion in the medical journals, and there are signs that it will lead to considerable difference of opinion, since already, with the object of "forestalling the outcry of antivivisectionists," the *Medical Times and Gazette* has condemned the publication of the paper as a "deplorably false move," whilst the *Medical Press and Circular* defends it. We do not, however, propose to follow this branch of the subject any further,—at least for the present,—for "when doctors disagree who shall decide?"

The point to which we wish now to refer briefly lies in another direction. Perhaps at no period in the history of the healing art has there ever been a more continuous crop of new remedies than at the present time; some of the medical journals may be fairly said to teem with them. Many of them consist of drugs already well known, but put to new uses; others are vegetable or chemical substances concerning the properties of which extremely little is yet known. In some instances, especially among the latter class, the substances are brought forward upon extremely frivolous grounds, unless, indeed, the prospect of gain to the introducers be deemed sufficient justification; in others, the very potency of the drug renders it a possible source of danger whilst so little is known about its physiological and therapeutic action. It is natural that a medical man wishing to try one of these remedies should seek to obtain all the information available respecting its properties and especially concerning the dose, and we have reason to know that pharmacists are frequently resorted to with this object. Such a course is indeed to be welcomed as exhibiting a reasonable dependence upon the intelligence of the pharmacist, and we try to show our recognition of this fact by keeping him *au courant*, to the best of our ability, with the published statements upon such subjects that appear to us to be trustworthy. Nevertheless, we would venture to remind our readers as to the necessity for extreme caution in the manner of communicating such information and suggest that they never should impart it in such away as to allow of the responsibility being shifted from the person who proposes to administer the drug. It is well known to all who have the opportunity of scanning the literature in which such remedies are advocated how loose the statements respecting the dose frequently are, and how unsuited for repetition without fuller information as to the conditions under which it has been advantageously administered. It is worthy of notice that in the case now under discussion, as Dr. MURRELL has pointed out, the largest dose which produced such disagreeable effects equalled only half the quantity recommended in a comparatively recent paper, and might *primâ facie* have been considered to be quite safe. Another illustration of our point may be found in a synthetically prepared derivative of chinoline that has recently been introduced under the name of "kairine," a further account of which will be found on another page. This substance appears to possess the property of lowering the temperature in fever cases to a marked degree, and it has been recently stated, without qualification and not for the first time, that kairine when "given in hourly doses of one gram, "after the employment of three to four grams, has a "more powerful and constant antifebrile effect "than quinine in doses of one and a half to two "grams." But we have reason to believe that its use in gram doses has been followed by disastrous consequences. Further, Dr. SHATTUCK, of Boston, recently reported a case where the administration of half gram doses to a "vigorous man" in the City Hospital produced cyanosis and cardiac depression, so that stimulants and heaters had to be freely resorted to, whilst on the same occasion Dr. DRAPER reported some cases and said that certainly in one of them the immediate effects of the kairine were dangerous to the life of the patient. Whether these results may find any explanation in the statement that older specimens of kairine may produce cyanosis and collapse we cannot say, the point which we wish to emphasize is that they illustrate the necessity for the exercise of caution in making statements with respect to such powerful and at present imperfectly studied substances. There is also the danger that doses which are not only safe, but beneficial, within certain limits, may be pushed to extremes. Thus, for instance, a medical journal recently quoted as a warning a case in which fifty grains of salicin were given every two hours, until three hundred grains were taken, and then it was made conditional upon the patient not being asleep. The next morning sixty grains were ordered to be taken every second hour and at midnight the patient died.

In accordance with our custom at this time of the year we have pleasure in recording the names of some of the pharmacists who have recently received municipal honours at the hands of their fellow townsmen. It is not pretended that the list is a complete one, but it includes such information as we have been able to obtain, either by direct communication or otherwise. Amongst the gentlemen who have been elected to the office of Mayor for the ensuing year are:—Mr. W. Ballard, Pharmaceutical Chemist, Abingdon, re-elected for the sixth time; Mr. A. H. Cox, Chemist and Druggist, Brighton, re-elected for the third time; Mr. H. Durden, Chemist and Druggist, Dorchester; Mr. J. Horsley, Chemist and Druggist, Hartlepool, re-elected the fourth time; Mr. F. J. Clarke, Chemist and Druggist, Lincoln; Mr. H. D. Simpson, Chemist and Druggist, Louth, for the third time; and Mr. H. Henley, Pharmaceutical Chemist, Lyme Regis, re-elected. In Scotland, Mr. John Babtie, Pharmaceutical Chemist, has been elected for the third time in succession Provost of Dumbarton, and Mr. William Gunn has been re-elected Chief Magistrate of the Burgh of Duns. In the last two instances the term of office is three years. In looking over this list one cannot help being struck with the evidence afforded that chemists and druggists are not only able to gain but successful in retaining public confidence.

* * *

In some cases that last week came before the Newport magistrates the point was again raised as to the application of the Sale of Food and Drugs Act in respect to the addition of colouring materials to articles of food. The charges under consideration related to the practice of imparting the usual colour to "German sausage" by means of "Venetian red," for which alleged offence summonses had been issued against three pork-butchers. The certificate of the public analyst stated that he had found this pigment in the proportion of 65 grains to the pound and that it had been added to conceal the presence of an excessive proportion of flour. On the other hand it was contended that the colouring matter was harmless and that it was an ordinary ingredient in such articles of food. Professor Attfield, who gave evidence for the defence, said that the addition of red oxide of iron to this kind of sausage and generally to the varieties of meat, fish, essence of anchovies, etc., which are commonly preserved in bottles and other vessels, is made simply and solely with the object of heightening the colour and appetizing appearance of such articles of food and in response to a popular fashion or demand, and that it is a fashion analogous to the colouring of cheese with annatto. The Bench accepted this view and dismissed all the summonses.

The new part of the 'Proceedings of the Philosophical Society of Glasgow' contains a paper by Dr. John Dougall, in which are recorded observations respecting the readiness with which milk absorbs gaseous and other emanations to which it is exposed, which although not new have an important bearing on the preservation of the public health. The experiments consisted in enclosing milk in a glass jar with some odorous substance, and after eight hours drawing off the lower stratum and testing it as to whether it had become impregnated with the substance. Every sample of milk was found to have contracted an odour from the substance to which it had been exposed. In the cases of musk and stale urine the smell is described as having been faint; in those of ammonia, chloroform and camphor moderate; in those of asafœtida, stale cheese and decayed cabbage, distinct; in those of paraffin oil, sulphuretted hydrogen, creasote, and human fecal matter, strong; in those of turpentine, onions, tobacco smoke, and ammonium sulphide, very strong; and in that of putrid fish, very bad. In addition the samples of milk that had been exposed to sulphuretted hydrogen, ammonia and ammonium sulphide gave evidence upon the application of chemical tests of the presence of those substances, whilst that which had been exposed to fecal matter gave the reactions for sulphuretted hydrogen. Dr. Dougall appears to attribute this absorptive property to the water which forms a natural constituent of the milk; but we think the analogous part played by fat in the process of *enfleurage* of perfumes points to another explanation.

* * *

In the annual report of the Chemical Examiners' Department, Calcutta, a copy of which has just reached us, reference is made to the death of a child through poisoning by strychnine, a decoction of "koochila" bark (*Strychnos Nux-Vomica*) having been supplied and administered instead of a decoction of "koorchee" (*Wrightia antidysenterica*), which had been ordered as a tonic and astringent. A similar accident happened in Calcutta about two years since. In connection with this subject Dr. Warden expresses his belief that India is the only British colony where there is no Pharmacy Act or law to regulate the sale of poisons. This belief is not yet, however, warranted by existing facts, although the time appears to be fast approaching when it will be, and it must be admitted that, at any rate, in respect to the larger towns, where Europeans reside in number, India ought not to remain an exception. The subject has already attracted the attention of the Indian Government, and in a resolution published last August the Lieutenant-Governor of Bengal said that "the general question as to the imposition of restrictions upon the sale of poisonous drugs demands and will receive separate consideration;" but up to the date of the report no orders had been issued on the subject.

* * *

So far as can be judged by the results of the cases in which human viscera were transmitted to Dr. Warden for examination, opium still remains the poison most frequently used in India for criminal purposes. Next to it comes arsenic, and then, after a considerable interval, aconite. In two stomachs examined in connection with abortion cases evidence was obtained of the presence of plumbagin, the acrid principle of *Plumbago rosea* ("lal chitra"). One curious case is reported as "suspicious," in which several persons, having found some sugar wrapped up in a plantain leaf in a prayer house, assumed that it had been offered by somebody in the name of the god and ate it. Shortly afterwards they were all seized with vomiting and purging and one died. No poison could, however, be detected, and it is possible that cholera was the cause of death; on the other hand, perhaps the deceased might have been alive now had he confined his communistic practices to more strictly mundane objects.

* * *

A dispensing difficulty discussed in our United States contemporary, *New Remedies*, with respect to the proper method of dealing with it, closely resembles one that is frequently the cause of perplexity to dispensers in this country. A pharmacist had a prescription presented to him ordering "Chlorine Mixture, ℥ij: S. 5 to 8 drops every hour as directed." Knowing that it was for a young child ill with scarlatina, he made a mixture according to a recipe in Griffith's 'Formulary,' consisting of chlorine water, lemon syrup and water. Next day, however, he was called to account for supplying a wrong medicine, the medical man saying that he meant a mixture containing potassium chlorate and hydrochloric acid, the formula for which was in the possession of a particular pharmacist. Being invited by the aggrieved pharmacist to express an opinion on the subject, our contemporary, whilst recognizing the inconvenience attending such practices by prescribers, very properly points out that to dispense in the absence of a definite formula for the "chlorine mixture" any other mixture that might be so called would be to assume the responsibility of its administration. In the case in question it is thought the dispenser did not act judiciously and that it would have been more prudent to have declined to put up a doubtful prescription, the decision resting with him whether it was in his interest to ask the prescriber's assistance or to refer the patient to the prescriber for more complete instructions.

* * *

We regret to have to record the death, on the 18th ult., of M. Edouard van der Heyden, the esteemed President of the Pharmaceutical Society of Antwerp, who also for several years has taken an active part in conducting the *Journal de Pharmacie* issued by that Society. The deceased was in the fifty-fourth year of his age, and the immediate cause of his death was a cancerous affection of the stomach.

* * *

On another page will be found a paper on "Seidlitz Powders," which we refer to here especially because it is the production of an apprentice who has put into practice a very good rule of trying to attain an intelligent acquaintance with the nature of the substances that pass through his hands during the routine of his daily work. Were more apprentices to follow the example of this young man we feel sure that there would be a sensible diminution in the feeling of "drudgery," of which we sometimes hear too much.

* * *

At the next meeting of the Chemists' Assistants Association, to be held at 53, Conduit Street, on Wednesday, November 21, a paper on "Glycerine and its Impurities" will be read by Mr. F. H. Alcock.

Provincial Transactions.

EDINBURGH CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

The second meeting of the sixth session was held in the rooms of the North British Branch of the Pharmaceutical Society, 119A, George Street, on Wednesday, 7th inst., at 9.15 p.m.; Mr. Claude F. Henry, President, in the chair.

After the minutes of the previous meeting had been read, the Secretary read the Prize Committee's report of the competitive examination for the apprentice members of the Association, which was held on October 19. Seven candidates had been examined, and the following were awarded prizes:—

1st *Prize*.—Mr. J. Parker Boyd, 58, George Street. (This prize takes the form of three months' instruction in practical chemistry under Dr. Stevenson Macadam.)

2nd *Prize*.—Mr. A. G. Sutherland, 119, George Street. (Griffith's 'Pharmacy,' Ince's 'Latin Grammar' and Macadam's 'Practical Chemistry.')

3rd *Prize* (Awarded by the President). — Mr. A. Rupell Bennet, 69, South Clesh Street. (Griffith's 'Pharmacy.')

The Committee reported that the papers submitted by the candidates were worthy of high commendation, and in no case could the candidates regret the appearance which they made.

The prizes were now presented by the President, the successful candidates being heartily applauded as they received their awards.

Mr. Peter Boa then gave a description of some "New Remedies" which he exhibited, the more important of which were convallaria majalis, ichthyol, kairine, naphthaline, paraldehyde and tannate of cannabin. In the course of his remarks, Mr. Boa advocated the institution of a Medical Committee of Investigation on New Remedies; because in many cases substances were found on a short trial to be comparatively worthless as therapeutical agents, one indirect result of their introduction being, that the pharmacist was left with unsaleable and often expensive stock.

A discussion followed in which several members supported Mr. Boa's suggestion. After a short interval for conversation, a paper on "Oleum Rusci" was read by Mr. MacEwan. This paper is printed on p. 381.

Mr. John R. Hill followed with an account of the toxic effects of *Cannabis Indica*, as experienced by an old member of the Association, which was listened to with great interest, and frequently occasioned loud laughter.

The Secretary then read the report of an Annual Pharmaceutical Competition Scheme, which had been drawn up by the Prize Committee.

The report was unanimously adopted.

In the course of the proceedings, votes of thanks were awarded to the Prize Committee, and to the gentlemen who read the papers.

The Secretary having given notice of several queries to be answered at next meeting, the proceedings were brought to a close.

HULL CHEMISTS' ASSOCIATION.

The annual meeting of the above Association was held at the Cross Keys Hotel, on Friday evening, Nov. 2. In the unavoidable absence of the President, Mr. Councillor George Myers, the Vice-President, Mr. Geo. Hoyles, occupied the chair.

The report of the Committee was read by the Secretary (Mr. C. B. Bell), which was considered satisfactory, nothing of any importance to disturb the trade having occurred during the past year. The adoption of the report was moved by Mr. Hoyles and seconded by Mr. Stoakes and carried unanimously. The Treasurer's balance sheet having been read was also unanimously agreed to.

The following were duly elected office-bearers for the next year:—President, Mr. George Hoyles; Vice-President, Mr. W. H. Hammond; Hon. Secretary and Treasurer, Mr. C. B. Bell; Committee—Messrs. John Oldham, F. W. Ellis, W. Price, J. S. Linford.

Votes of thanks were heartily accorded to the various officers for the services they had rendered during the past year.

HAWICK PHARMACEUTICAL ASSOCIATION.

The November meeting of this Association was held on Tuesday, November 6, when there was a good attendance; Mr. Maben, Honorary President, in the chair.

The minutes having been read and approved of, Mr. William B. Rawlinson read a paper on—

Seidlitz Powders.

In introducing the subject, the essayist stated that he had selected it in consequence of the advice of the Honorary President at the opening meeting of the Association, which was to the effect that each member should try and write a paper on the first thing he made next morning. He decided to follow this advice, and the first preparation he happened to make was seidlitz powders; hence this paper. Dealing first with his subject historically, he traced the origin of the word, its connection with a mineral water, and its subsequent connection with powders, which latter must have come into existence well on for a century ago. He then referred to the composition of the powders, their preparation, the papers in which they are wrapped and their preservation, giving also an account of the discovery and uses of Rochelle salt. He then continued:—

The usual way in which seidlitz powders are administered is by dissolving the contents of the blue paper in water and then adding the contents of the white. When this is done a brisk effervescence takes place, carbonic dioxide being given off in the form of gas. The resulting product will vary in accordance with the proportions of tartaric acid and soda: if the latter be in excess the solution will contain Rochelle salt, neutral tartrate of soda and bicarbonate of soda, and will have an alkaline taste; if the former be in excess it will contain Rochelle salt, neutral nitrate of soda and acid tartrate of soda, and the taste will be acid; if neither is in excess the resulting process will be neutral, that is, provided the Rochelle salt be neutral. Professor Attfield gives as a formula 3 parts (120 grains) of Rochelle salt, 1 part (40 grains) of soda, and 1 part (40 grains) of tartaric acid. Now, as 40 grains of the soda only require 35 of the acid to make a neutral salt, there is here an excess of acid to the extent of 5 grains, which he states is utilized on the formation of acid tartrate of soda, evidently forgetting that Rochelle salt is rarely neutral. A more common formula, however, gives the above proportions for the blue paper, and 35 grains of acid for the white, so that the result is certain to be neutral if not alkaline, while a third gives 2 parts of Rochelle salt and 1 of soda, which is certain to give a decidedly alkaline draught. I have already stated that seidlitz powders are not official in our Pharmacopœia. In the other three principal Pharmacopœias they find a place, the various formulas being as follows:—

	Soda tart. Grains.	Sodæ bicarb. Grains.	Acid tart. Grains.
United States Pharmacopœia "*Pulvis effervescens compositus*"	120	40	35
German Pharmacopœia—"*Pulvis acrophorus laxans*"	116	38	31
French Pharmacopœia—"*Poudre gazogène laxative*"	93	31	31

In my opinion seidlitz powders ought to be included in our own Pharmacopœia, and I trust the new edition will contain a formula for them. The reasons in favour of this are obvious. At present every chemist is allowed to use his discretion as to the composition of this popular medicine, with the result that at one shop an alkaline, at another an acid, and at a third a neutral powder is obtained, and even in some cases all three may be got at the same shop and at the same time. As the precise therapeutical effect of each of these powders is different, this will doubtless often be a source of annoyance, not to speak of perplexity to the seidlitz drinking public.

Before going further, let me refer to what is known as double strong or extra strong seidlitz powders. These usually consist of the same quantity of acid and of soda, but a larger proportion of Rochelle salt. This proportion varies, different chemists adopting different percentages, but a very common form is simply to double the amount of Rochelle salt. The double strong powders are in most cases used as a direct purgative, and it is therefore doubly desirable that an authoritative formula should be given for them. Another consideration that draws attention to this point is the fact that at present many chemists do not weigh their powders; they simply measure them, the result being that great variations are observed in the contents of both white and blue papers. This applies more especially to ordinary seidlitz, the usual practice in the case of double strong being to measure one portion and weigh the remainder. The effect of this random system is frequently found in the different sizes of powders obtained from the same shop. Now this should not be, and if the powders were official and the inspector of food and drugs did his duty it would not be. It has often been brought before the readers of our various journals that this loose practice exists and ought to be put down, and being somewhat curious to ascertain the actual state of affairs for myself, I obtained samples of powders from ten shops in different parts of the country, some of them being the best houses in Edinburgh. I procured three ordinary and three double strong powders from each, and accurately weighed the contents of every paper. Mr. Maben kindly undertook to estimate the relative proportions of Rochelle salt and bicarbonate of soda in the blue paper, and I have thus been enabled to give a pretty complete table, which is appended to this paper. Without going into a regular analysis of this table, I wish to direct your attention to one or two facts which are not apparent, as the powders are not given in the order in which they were purchased; each white paper, however, belongs to the blue paper of the same number.

As to the ordinary seidlitz powders, the average weight of tartaric acid was 38 grains, the lowest weighing 24 and the highest 53. The greatest difference in powders from one shop was 11 grains in one case and 10 grains in another. The average weight of the blue papers was 162 grains—the lowest being 107, the highest 245. The greatest differences in powders from one shop were 39, 32 and 28 grains. There were frequent instances where acid and alkaline powders were got from the same shop. In some instances the powders had been carefully weighed, but in others great differences in the weight render it quite apparent that measurement—and even that not very carefully done—had been adopted.

In reference to the double strong powders the average weight of the acid powders was 36 grains, the lowest 28, and the highest 68; greatest difference in powders from one shop, 17 grains. The average of the alkaline powders was 266 grains, lowest 187, highest 365; greatest differences in powders from one shop being 72 in one case and 60 grains in another. Alkaline and acid powders were also noted here in several cases, and it is curious to observe that what is given for the double strong powder in one shop would not pass for the ordinary powder of another. The same remark as to weighing and measurement applies here, but though there were quite as many variations in weight, these were not on the whole so extensive as in the ordinary seidlitz powders.

These anomalies are very striking and ought not to exist longer, and I trust that we may have in our new edition of the British Pharmacopœia a definite and authoritative recipe for both ordinary and double strong seidlitz powders.

30	27	107	60	47	30	31	224	182	42

Note.—As Rochelle salts may vary in alkalinlty, the proportions here given may not in all cases be strictly correct; the calculation is made from the alkalinity of Howard's sodæ tart.

After the reading of the paper, the subject was discussed by Messrs. Craig, Hewat, Hislop, and others, and, on the motion of the Chairman, a vote of thanks was awarded to Mr. Rawlinson.

Proceedings of Scientific Societies.

BRITISH PHARMACEUTICAL CONFERENCE.

(*Continued from page* 358.)

A note was then read on—

The State of Combination in which Morphia exists in Opium.

BY D. B. DOTT, F.R.S.E.

Who it was that first discovered (or guessed) that opium contains morphia sulphate, I have not been able to ascertain; the published references to the matter being few, and not very informatory. At a former meeting of this Conference (1879), Professor Flückiger gave it as his opinion that morphia is "present in opium as a sulphate, at least for the most part." This conclusion was arrived at from the observation, that an alcoholic solution of opium contains sulphuric acid which cannot exist as inorganic sulphate, and must therefore be present as alkaloidal salt. In the discussion which followed the reading of the Professor's paper, Mr. Naylor appears to have upheld the view that the morphia exists partly as meconate, and partly as sulphate; but the report of his remarks is obscure and ambiguous. The latter opinion I believe to be correct, though not for the reasons given by Mr. Naylor, who appears to found principally on the alleged fact that crystals of meconate and sulphate are formed in solutions of opium. Although I have obtained crystals of morphia sulphate from an opium extract, I never yet observed in it crystals of meconate.

The facts which render it almost certain that morphia exists in opium both as sulphate and meconate, are briefly as follows:—

1st. An aqueous extract of opium contains sulphuric acid in sufficient quantity to combine with the whole of the morphia.

2nd. The same extract contains meconic acid in quantity insufficient to convert all the morphia into meconate.

3rd. The extract contains inorganic and organic bases, with which the sulphuric acid will unite in preference to the morphia; and the remainder of the sulphuric acid will not suffice to combine with all the morphia.

Seeing then that the sulphuric acid, which is free to combine with the morphia is insufficient to unite with the whole of the alkaloid, it is evident that part of the morphia must exist as meconate. From the acid nature of opium solutions, and on account of the great difficulty (if not impossibility) of obtaining crystalline meconate from them, I formerly concluded, and still consider it probable, that the morphia meconate present in opium is the *acid* salt. This, however, is not absolutely certain, as the meconic acid may be partly combined with narcotine, papaverine, etc., while the colouring and extractive matters might prevent the neutral meconate from crystallizing. The subject is one by no means free from difficulty, and would require very many experiments to thoroughly clear it up. I have discussed the matter more fully in a paper read last session before the Royal Society of Edinburgh.

The President said the Conference was very grateful to Mr. Dott for this paper, but after what the author, an authority on such matters, had said respecting the difficulty surrounding the question as to the condition in which morphia existed in opium they could not expect much discussion.

A vote of thanks was passed to the author.

The next paper read was on—

Sweet Spirit of Nitre.

BY ALFRED CLAY ABRAHAM, F.C.S.

Although the term sweet spirit of nitre does not occur in the British Pharmacopœia, and consequently that name cannot strictly be applied to the preparation now official, the latter was undoubtedly intended as a substitute for the older preparation, and I shall apply the term indifferently to both. I need not enter into the history of this preparation, which will be found in Christison's 'Dispensatory,' and more recently in a comprehensive article by Warington in the *Pharmaceutical Journal*, [2], vol. vii., p. 7.

It will suffice to remind you that until 1826 the process adopted had been almost, if not quite, universally that of distilling together a mixture of nitric acid and spirit of wine. The strength and proportions of these ingredients differed from time to time very considerably, but neglecting secondary reactions (however important they may have been), we may, I think, consider that the necessary result would be the production of tolerably constant proportions of nitrite of ethyl and aldehyde. No doubt some of the more violent formulæ, *i.e.*, those in which strong nitric acid or that acid in large proportion was used would cause the oxidation to be carried much further. As to the probability of this I may refer to Mr. Alsop's experiments, which will be found recorded in the *Pharmaceutical Journal*, [2], vol. iii., p. 425. This gentleman found that by dropping the spirit gradually into the acid scarcely anything but acetic ether was formed. This would seem to show that it was by no means only the aldehyde which suffered decomposition. I should perhaps here say that what I am endeavouring to show is that the preparation so long known under the name of sweet spirit of nitre, and which obtained and maintained a certain reputation, was essentially an impure solution of nitrous ether and aldehyde, containing approximately an equal number of molecules of each of these compounds.

In the Dublin Pharmacopœia of 1826 a formula was given for the preparation of nitrous ether, in which the nitric acid was formed during the distillation by the action of sulphuric acid upon nitrate of soda.

In 1839 the Edinburgh Pharmacopœia gave directions for the preparation of nitrous ether from strong nitric acid of 1·500 sp. gr. and subsequent purification, first with milk of lime and afterwards by shaking with a concentrated solution of chloride of calcium and separating the ethereal liquid which rose to the surface. The London Pharmacopœia, however, never departed from the old process.

In the first British Pharmacopœia of 1864 an entirely new process was adopted, which consisted in distilling together nitrite of soda, sulphuric acid and spirit of wine.

The main objection to this plan was the difficulty and expense of preparing a satisfactory nitrite of soda, which when prepared, as directed, seldom, I believe, contained more than about 20 per cent. of the nitrite. Shortly before the publication of our present Pharmacopœia in 1867, Professor Redwood read a paper upon "Spirit of Nitrous Ether," a report of which will be found in the *Pharmaceutical Journal*, [2], vol. viii., p. 508. Professor Redwood's experiments showed, what I believe has never since been denied, that when nitric acid and spirit are distilled together, no nitrous ether to speak of is formed until the proportion of spirit has been reduced to about four times that of the acid, at which point the reaction becomes violent, and of course produces a number of secondary products, to none of which can the normal action of the preparation be imputed. The condemnation of the old nitric acid process was based upon these grounds.

The Dublin and Edinburgh processes he condemned for three reasons, viz.:—(1) The difficulty of carrying them out on the large scale; (2) The excessive cost, and (3) The alteration in character of the product. The nitrite of soda process was condemned on the grounds I have before named, and a number of other processes now forgotten were rejected for reasons which he states. Amongst the latter was the process of forming the nitric acid in the presence of the spirit by the use of a nitrate and sulphuric acid.

This was stated to be open to the same objection as the Edinburgh and Dublin processes, but in what way this was so Professor Redwood did not state.

Professor Redwood then described a new process which was shortly afterwards adopted in the British Pharmacopœia, and which is too well known to all to need any description. If I had been as well aware a few years since as I am now of what had been done by well-known chemists in attempting to improve this preparation I should have been discouraged from making any further experiments and you would probably have been spared the infliction of this paper. I was not, however, aware of what had been done and was therefore induced to consider why the pharmacopœial product so soon spoiled or at least became deteriorated, and why the old fashioned preparation still remained so largely in favour and had the reputation of keeping so much better.

I mention the questions which arose in my mind not because I have been able to solve them, but because they drove me to the conclusion that there must be something formed when following the official formula which had a destructive action upon the other ingredients. I was the more induced to favour what we may call the direct nitric acid method from a conviction that the explanation of the pharmacopœial process generally received was erroneous and that it was more correct to impute the moderate action and constant temperature peculiar to that process rather to the action of the sulphuric acid upon nitrate of copper, or to the increase of the boiling point by the admixture of sulphuric acid, than to the formation of nitrous acid.

My first experiment (*a*) was the following and was made to test the accuracy of my supposition that the production of nitrous ether was based upon the action of sulphuric acid upon nitrate of copper.

3 ounces of copper
and 9 fluid ounces of nitric acid

were caused to react, the result being of course a waste of one-fourth of the acid, which reduced the available quantity to $6\frac{3}{4}$ fluid ounces, *i.e.*, 50 per cent. more than ordered in the British Pharmacopœia.

Sulphuric acid, 3 fluid ounces,
Spirit rect., $1\frac{1}{2}$ pint,

were then mixed, added to the nitrate of copper previously formed and distilled.

The reaction proceeded with great regularity and the fluid ounce product was 4 pounds, 9 ounces $= 96\frac{1}{2}$, *i.e.*, 4 fluid ounces more than the British Pharmacopœia directs to be produced.

From this 3 to 4 per cent. separated when the Pharmacopœia test with solution of chloride of calcium was applied. This promised well, but as a green insoluble powder, which I took for basic nitrate of copper remained in the retort, I was induced to try using a smaller quantity of the acid.

3 ounces of copper,
6 fluid ounces of nitric acid,

were combined, and the product, containing the nitric radical equal to $4\frac{1}{2}$ fluid ounces of nitric acid, *i.e.*, the B.P. quantity, was treated as before. Product $87\frac{1}{2}$ fluid ounces which separated nothing with solutions of chloride of calcium. This certainly would not do, and as No. 1 had only one advantage over the Pharmacopœia, viz., the greater regularity of its distillation, and on the other hand required the use of much more copper, and twice as much nitric acid, I looked out for some base which would fulfil the following requirements viz.:—

1. Be cheap.
2. Constant in composition.
3. Easily decomposed at the required temperature by the sulphuric acid,
4. Exist either in the state of nitrate in commerce, or in that of some compound which could be converted into a nitrate without loss of nitric acid.

Calcium seemed to answer these requirements best, but I was afraid that it might liberate its nitric acid too rapidly.

The following was tried:—

$\left.\begin{array}{l}\text{Acid. nitric., } 4\frac{1}{2} \text{ fluid ounces}\\ \text{Calc. carb. præcip, } 3\frac{1}{2} \text{ ounces}\end{array}\right\}$ combined.
$\left.\begin{array}{l}\text{Acid. sulph., 3 fluid ounces}\\ \text{Sp. rect., } 1\frac{1}{2} \text{ pint}\end{array}\right\}$ mixed.
Sp. rect., 3 pints. In receiver.

The carbonate of calcium was placed in a flask of about a gallon capacity—although this is much larger than necessary—the nitric acid was poured gradually upon it and the flask then set aside for the contents to cool. I believe that in my first experiment the nitrate of calcium was left for several days, but this is quite immaterial.

The sulphuric acid was mixed with a pint and a half of the spirit, poured upon the nitrate and distilled into the remaining three pints of spirit.

The distillation proceeded with great regularity from the beginning to the end; the product was $86\frac{1}{2}$ fluid ounces of a liquid of specific gravity ·8453 at $60\frac{1}{2}$° F., and separated 3 to 4 per cent. by the chloride of calcium test.

This product appeared in every way equal to that made by the Pharmacopœia process, and as the quantity drawn over, viz., $86\frac{1}{2}$ fluid ounces, was 4 fluid ounces or nearly 5 per cent. greater than that authority directs to be recovered the result could not be considered unpromising. I should say that the first $82\frac{1}{2}$ fluid ounces were tested and found only to separate about 1 per cent., but the remaining 4 fluid ounces of product raised it to the strength I have named. This latter fact and some other indications which I had during the distillation showed that the quantity of spirit added with the sulphuric acid was too great and I, therefore, modified the form thus:—

$\left.\begin{array}{l}\text{Acid. nitric., } 4\frac{1}{2} \text{ fluid ounces}\\ \text{Calc. carb. præcip., } 3\frac{1}{2} \text{ ounces}\end{array}\right\}$ combined.
$\left.\begin{array}{l}\text{Acid. sulph., 3 fluid ounces}\\ \text{Sp. rect., 1 pint}\end{array}\right\}$ mixed.
Sp. rect., $3\frac{1}{2}$ pints. In receiver.

In this case the nitrate of calcium was used the day after it was made, but in other respects the same details as before were followed:—

Product, 4 pounds 10 ounces $= 87\frac{1}{2}$ fluid ounces.
Specific gravity, ·8463.
Separated, 3—4 per cent.

The distillation occupied less than one hour. I liked this process much better than the Pharmacopœia one, but it had one drawback which I imagined might be fatal to it as a manufacturing process on the large scale. The sulphate of calcium remaining in the retort forms a magma from which in quantity I imagined it likely that some difficulty might be experienced in distilling even as much as the Pharmacopœia directs to be drawn over, without applying such a heat as would perhaps injure the product or partially dehydrate the sulphate of calcium, and consequently water the product.*

To avoid this possible difficulty, I fell back upon my supposition, that possibly the sulphuric acid might so raise the boiling-point of the mixture of nitric acid and spirit as to reach the temperature necessary for the formation of the nitrite of ethyl.

The proportions of nitric acid, sulphuric acid and spirit ordered by the Pharmacopœia were therefore mixed and distilled into the remaining spirit. The product, perhaps through some neglect, was not satisfactory.

I suspect, however, that a continuous process in which the supply of spirit and nitric acid should be adjusted so as to maintain a regular and proper temperature would work well, although unsuited to a Pharmacopœia which must, when possible, give a process adapted as well to the small as to the large maker.

Since making these experiments, I see that the United States Pharmacopœia has adopted such a process as I

* Since writing, Mr. Michael Conroy has relieved my mind upon this point by very kindly preparing a large batch in Messrs. Evans, Sons and Co.'s laboratory. I have to express my obligation both to him and to them.

myself tried (form E.), but I have not tested its capabilities.

I have tried some other formulæ for the manufacture of this preparation, but their results do not justify me in occupying your time by recounting them.

And now, gentlemen, having mentioned such experiments as seemed to me of interest, I will, with your permission, repeat what I said before, viz.:—That the preparation which gained a certain reputation under the name of spiritus nitrici dulcis, was one produced by the direct action of nitric acid upon spirit of wine.

Nitrite of ethyl was long ago found to be a constituent of this, and it was assumed, on very slender grounds, I believe, that to it alone was due the medicinal activity of the preparation.

Rimmington says (*Pharm. Journ.*, [3], viii., 341) that nitrous ether when free from aldehyde and other oxidized products will keep well in well stoppered and full bottles for four to six months, but as samples *d* and B.P. (see table) have been kept seven months in bottles *not full*, exposed to bright light in a warm room, and, moreover, have had a number of small samples taken from them, as would be the case in dispensing, it would seem as if the aldehyde did not exert a very deleterious action. Mr. Rimmington also points out how valuable the nitrous acid formed in the stomach from the nitrite of ethyl may be in febrile diseases, but he forgets that acetates are *known* to do what he only suggests as a function of the nitrous acid and so fails to appreciate the value of the aldehyde, which we may fairly assume will be converted into acetic acid and afterwards into an acetate *when it reaches the blood*, where its action is required.

I believe we have as much right to say that aldehyde is the active ingredient as to credit nitrite of ethyl with being such. Holding these views, I have made no attempt to prepare a pure solution of nitrite of ethyl in spirit, and have indeed practically returned to the old process, so modified, however, as to eliminate the sources of loss and the impurities due to a very violent reaction. The British Pharmacopœia process has been supposed to produce less aldehyde than the old process, and proportionately, no doubt, this is true, because I suppose there is no doubt that most of the nitrous ether was formerly lost.

That this supposition with reference to the aldehyde is not correct, however, when the Pharmacopœia product is compared with the product of form *d*, is, I think, roughly shown by adding to both a sufficient quantity of caustic potash. The colour produced is almost exactly the same. I would venture to suggest that formula *d* is a better one than the pharmacopœial, for the following reasons:—

1. The product is 5 per cent. greater.
2. The cost is less.
3. The process is more analogous to the old one.
4. Occupies much less time.
5. The distillation is much more regular.
6. The proportion to be distilled is one-third less.

Advantages 4, 5 and 6 recommend it as a manufacturing process.

There are other points which may be noted in its favour, although we have no direct means of estimating their value.

When the impure nitrous ether produced by the Pharmacopœia process is mixed with the spirit and shaken, an evolution of gas always takes place, which will blow out the stopper unless it is removed.

The process which I recommend does not produce this result.

The residue in the retort when operating by the Pharmacopœia process has a very nauseous smell, forcing one to believe that some very complicated secondary reactions have been going on.

The residue of process *d* is perfectly sweet.

Of course these virtues would count for nothing if the product did not equal that produced by the present official process. That it does, however, I have satisfied myself and hope to be able to satisfy others, although my analytical investigations have by no means been carried out to the extent to which I should have wished, or, indeed, as far as they would have been had business permitted.

All tests have been comparative, that is to say they have been applied to the products of form *d* and the British Pharmacopœia, made on the same day with the same apparatus and ingredients. No satisfactory test for nitrous ether, when mixed with spirit, aldehyde, etc., has yet been devised. As far as I am aware those of Dupré and Muter, which will be found in the *Analyst*, vol. iv., p. 121, must, I think, estimate aldehyde, which could hardly escape oxidation, at least to some extent during the processes employed.

I have therefore simply titrated, when fresh and practically neutral, with liq. sodæ, and satisfied myself that the quantities required by both were practically the same.

The taste of the two preparations is indistinguishable, and when fresh they are equally neutral.

The sp. gr. of product from form *d* is certainly slightly lower, but this, if not merely due to the recovery of the 5 per cent. more spirit, could easily be rectified by using a dried nitrate of calcium.

With regard to the keeping properties of the respective preparations I must refer you to the table, but with regard to the amount of acidity I must admit a doubt as to whether the pharmacopœial product does not liberate less free acid when kept than the product of form *d*. Bicarbonate of potash did certainly seem to cause more effervescence with the latter than with the former. Thinking that this might be due to the more rapid decomposition of the nitrite of ethyl, I applied the following test, which, however, seems to me to be a more promising one for the general quality of the preparation than of any value for the purpose for which I originally applied it.

To an ounce of water I added a crystal of neutral iodide of potassium, 100 fluid grains of the sample and estimated the liberated iodine with volumetric solution of hyposulphite of soda.

The results, which I think are interesting, are tabulated, and fairly show, I believe, the natural loss due to time. One thing at least seems perfectly clear, viz: that the success of the B.P. process is not due to the formation of nitrous acid, but to the increased boiling point resulting from the presence of the sulphuric acid, which is gradually eliminated as the distillation proceeds by its action upon the copper, or upon nitrate of copper, and thus maintains a proper equilibrium.

The above test being dependent equally upon the nitrite of ethyl and the aldehyde, or the acetic acid formed from it, would seem a very suitable one for a preparation in which both have an equal claim to recognition.

And now, gentlemen, having, I fear, exhausted your patience, I have only to apologize for bringing before you a subject which to properly treat would require more time than I have been able to give to it, and I hope you will regard the formula which I have recommended, not as a perfected one, but merely as one sufficiently successful to justify further experiment.

In connection with this subject, I may be permitted to describe an arrangement which I have devised to overcome what to me was always a great difficulty, due to the utter repugnance which fresh spirit of nitrous ether has for being enclosed in a tube, and mixed with chloride of calcium solution.

This piece of barometer tube is or ought to be divided into three portions, each holding 50 fluid grains, and the lower one again divided into hundredths. The peculiarity consists merely in substituting for a stopper or cork a short piece of strong rubber tubing, which can be compressed by means of a strong screw pinchcock.

This allows of a certain amount of expansion, and obviates all difficulty.

		Product f. oz.	Sp. gr.	Separated per cent. when fresh.	Separated when three months old.	Separated when seven months old.	I liberated from KI. when fresh.	I liberated when seven months old.
	Cu 3 oz., HNO_3 3 f. oz., combined. H_2SO_4 4 f. oz., sp. rect. 1½ pint, mixed. Sp. rect. in receiver, 3 pints.	86½	·845	3–4				
b.	Cu 3 oz., HNO_3 6 f. oz., combined. H_2SO_4 3 f. oz., sp. rect. 1½ pint, mixed. Sp. rect. in receiver, 3 pints.	87½	not taken.	nothing.				
c.	HNO_3 4½ f. oz., $CaCO_3$ 3½ oz., combd. H_2SO_4 3 f. oz., sp. rect. 1½ pint, mixed. Sp. rect. in receiver, 3 pints.	86½	·8453	3–4				
d.	HNO_3 4½ f. oz., $CaCO_3$ 3½ oz., combined. H_2SO_4 3 f. oz., sp. rect. 1 pint, mixed. Sp. rect. in receiver, 3½ pints.	87½	·8463 at 57°	3–4	3	2	104	100
e.	HNO_3 4½ f. oz., H_2SO_4 f. oz. } mixed. Sp. rect. 1½ pint. Sp. rect. in receiver, 3 pints.	87½	not taken.	nothing.				
P.B.	HNO_3 4½ f. oz., H_2SO_4 3 f. oz. } mixed. Sp. rect. 1½ pint. Sp. rect. in receiver, 3 pints.	82½	·8456 at 57°	3–4	3	2	106	101

The above samples were all made by using a glass flask, heated on a steam funnel, as described and figured in the *Pharmaceutical Journal* of May, 1882.

I need hardly, in a paper of this nature, refer to the most unsatisfactory character of the Pharmacopœia tests, tests which if regarded as applicable to a preparation not new would condemn the most conscientious pharmacist in the country to an invidious police charge. Some latitude must be allowed or chemists will be obliged in self-defence to make the preparation originally considerably above the strength indicated.

The President moved a vote of thanks to Mr. Abraham. He said a vast deal might be said on this subject, but he hoped members would condense any remarks they had to make, bearing in mind that at present no one quite knew what it was they spoke of when referring to sweet spirit of nitre. He did not know that anyone could say that the original sweet spirit of nitre was a solution of nitrite of ethyl at all, or that it was a solution of aldehyde. It was quite certain none of the processes which had been proposed yielded a perfectly definite article. For anything they knew, the substance might owe its activity mainly to nitrous ether, to aldehyde, to other things, or to a combination of all. These matters had never been scientifically investigated by therapeutists. He had thrown out a hint once or twice that it would be extremely desirable if some gentleman well acquainted with therapeutics would say what was the action so far as he could ascertain it, of a solution in spirit of nitrous ether, and of a solution in spirit of aldehyde, and that might induce pharmacists to produce an article which should have a definite composition. With regard to the tests, there was none on which reliance could be placed which would give them information they did not at present possess. They could demonstrate the presence of nitrite of something in sweet spirit of nitre, and the presence of aldehyde, but he feared up to the present time there was no method of quantitatively estimating satisfactorily either the amount of aldehyde, of nitrous ether, or of any other substance. He hoped that a knowledge of this preparation would be extended sooner or later, and there was some hope it would be so, because a useful pamphlet had been published on the subject by Professor Eykman, of Tokio, an abstract of which had appeared in *New Remedies* of May, 1882, and the *Pharmaceutical Journal* of July 22, 1882, in which the author gave a method of estimating the nitrous ether in sweet spirits of nitre, or spirit of nitrous ether, or whatever else it might be called. That method depended on eliminating nitric oxide gas, and estimating its volume; it did not take any account of either nitrous or nitric acid present, but it was to be assumed that anyone experimenting would ascertain the absence of these substances. It was possible it might yield trustworthy indications as to the amount of nitrite of ethyl in the article experimented on, and he recommended it to those investigating this subject in order that they might arrive at some reliable data.

Mr. Williams thought it hopeless, as he had often said, to produce anything like absolute or uniform results by mixing together in a retort certain ingredients, and distilling something out of that retort. He would say no more on that matter, because all the researches of pharmacists tended to prove the same thing. He had attempted to make sweet spirit of nitre synthetically. He had made a 10 per cent. solution of pure nitrite of ethyl condensed in absolute alcohol, and the result was not, as far as flavour was concerned, sweet spirit of nitre. He had then made a 10 per cent. solution of pure aldehyde in alcohol, and the result was certainly not sweet spirit of nitre. Mixing the two together in equal proportions the result had no resemblance whatever to sweet spirit of nitre, and no one would accept it as the sweet spirit of nitre the public required. Chemically speaking, therefore, sweet spirit of nitre must be something different to what it was often assumed to be, a mixture in equal parts of nitrite of ethyl and aldehyde. The aldehyde was very objectionable, so offensive indeed that if present in any large proportion it would spoil the flavour of any sweet nitre if it contained anything like the proportion of 5 per cent. He had had lately to do with the body recently introduced to medical notice, called paraldehyde, in which three molecules of aldehyde were polymerized into one of the new body. This new body was believed to be a very potent and powerful medicinal agent. They did not know much about its real activity at present, but it promised to be a very important drug and chemical agent of the future. But it was remarkable that the flavour of this particular modification of aldehyde was so similar to that of sweet spirits of nitre that he believed it was to a great extent the real ingredient combined with nitrite of ethyl, which they had been seeking for. Pure aldehyde when brought into contact with a very small quantity of hydrochloric or sulphuric, or almost any acid, was converted, not by any combination taking place between the acid and the aldehyde, but by an internal re-arrangement of molecules and condensation, so that three molecules of the aldehyde were condensed into one molecule of the new body. This change might be seen going forward in the flask in which the operation was conducted, in the most beautiful manner. The aldehyde, which was so volatile that it could hardly be condensed, and so disagreeable that its vapour could hardly be breathed, and insoluble in water, and with a flavour that could not be tasted without offence, became a mild tasting body, boiling at 120° Cent., changed in all its nature, except probably in its medicinal activity, and perfectly soluble in water or solution of chloride of calcium. He believed this body was produced naturally by the ordinary process adopted in making sweet spirit of nitre, especially when the operation was conducted slowly. In carefully working with pure aldehyde he found it could not be entirely converted into paraldehyde in one operation; about one third of the aldehyde was converted partly into acetic ether, and partly acetone, and these two bodies had been distinctly separated in a pure state. He could answer for it, however, that a very small quantity of free acid was capable of converting a large portion of the aldehyde into paraldehyde, acetic ether, and acetone, while the nitrite of ethyl, which would also be produced, as part of the reaction of the Pharmacopœia process for making sweet spirit of nitre, would go to make up the complex body which they knew as sweet spirit of nitre.

Dr. Symes said the remarks of Mr. Williams were very suggestive; but if paraldehyde was the active ingredient in spirit of nitrous ether it could not be *sweet* spirit of nitre, because, as far as he could judge, paraldehyde when considerably diluted was anything but *sweet*. He wished to remark that there was a practical matter which affected them all, and that was that whilst their knowledge was so uncertain about sweet spirit of nitre, it did seem a great hardship to pharmacists that on the authority of an uncertain test gentlemen were frequently prosecuted and fined for not being able to produce a body which it was pretty clearly shown could never be produced with certainty twice alike.

The President remarked that the case to which he believed Dr. Symes referred was decided on analytical evidence, depending, not on the pharmacopœial tests, but on the permanganate test, quite a recently proposed method.

Dr. Symes said the point was that this body was not constant to any known test.

Mr. Moss said he did not know what the state of the law on sweet spirit of nitre in the United States was, but if he remembered rightly, in the report of the committee of revision of the U.S. Pharmacopœia, it was recommended that some such process as that of the B.P. should be employed; that copper, sulphuric acid and nitric acid should be distilled together in a retort, and something obtained from them; the something, whatever it was, was then to be mixed with a saturated solution of chloride of calcium in order to separate this same substance which was obtained in testing spirits of nitre by the pharmacopœial test. It would look as if in America they devised their process rather with a view of standing this test than from any notion they might have as to what sweet spirit of nitre ready was.

Mr. Naylor said he would not enter into the question of the manufacture or composition of sweet spirit of nitre, but he did think it very desirable that in the coming Pharmacopœia the method suggested by Dr. Dupré for the estimation of the nitrite radicle should be adopted. There was certainly a make of spirit of nitre obtainable, which, when examined by that method would at any rate correspond to 3 per cent. of crude nitrous ether. In the new U.S. Pharmacopœia the manufacturing method with copper was abandoned.

Mr. Whitley Williams said he believed that in sweet spirit of nitre there was a considerable proportion of things which gave nitrous acid, which were not in any sense of the term nitrites. Sweet spirit of nitre probably contained a considerable quantity of nitroso-aldehyde compounds.

Mr. Dott remarked that with regard to the physiological action of this drug, Professor Matthew Hay, of Aberdeen, confirmed his own opinion that the diuretic action of sweet spirit of nitre was due to the nitrous radicle in the compound; his experience with other nitrites agreed with that.

Mr. A. C. Abraham had listened with great pleasure to Mr. Williams's remarks, and was not surprised that his solution of nitrous ether was not like sweet spirit of nitre; he did not think anyone would expect that it would be. With regard to paraldehyde, he was extremely pleased to hear what Mr. Williams said. He had, indeed, only a few days since expressed to Mr. Conroy his suspicion that possibly paraldehyde was one of the active principles of sweet spirit of nitre. His attention had only recently been called to this body and his suspicion was not founded upon such a basis as Mr. Williams had mentioned; still whether paraldehyde or aldehyde, it was the same group of molecules whether in the treble or single state. After all, the action of sp. æther. nit. was not supposed to be so much sedative—while that of paraldehyde was—as diuretic, and he doubted whether, supposing paraldehyde was present, the value of the preparation might not be judged by the amount of nitrous acid liberated in following out the test he had suggested. The framers of the United States Pharmacopœia were to his mind considerably too radical. They had had a glycerine period, and now they had one which might have some other feature equally objectionable in it. In matters of this kind they should be cautious, and stick to the old processes as much as possible; they knew that the direct action of nitrous acid on spirit produced a preparation which was wanted, which had a certain efficacy, and he thought they should give a certain preference to that. He hoped that he had shown that it produced as much nitrous ether and aldehyde as the Pharmacopœia process, but it could easily be increased in strength in that direction if desired.

A paper was then read on—

An Examination of Some Samples of Pitch and Asphalt.

BY E. DAVIES, F.I.C., F.C.S.

Having had a sample of American asphalt sent to me, suspected of being stearine pitch, I found that very little information could be found in books with reference to either pitch or asphalt. I have, therefore, collected samples of all kinds of pitch or asphalt which I could obtain, and although I have been unable to meet with some kinds occasionally imported, as Cuban and Mexican, I trust that the notes which I have made will be found to have some value. No attempt has been made to analyse the organic matters in these varied products. They are no doubt mixtures of great complexity and, so far as manufactured pitch is concerned, of variable composition, according to the heat used in their manufacture. As my object was mainly the identification of the various commercial articles, I have only determined the ash, the sulphur, and the amount soluble in petroleum spirit sp. gr. 700. The last of these determinations does not admit of very great precision. In almost all the samples there is a substance highly fluorescent, and very slightly soluble in petroleum spirit, to completely remove which was impracticable without such prolonged treatment as was inconvenient. I therefore performed the extraction as follows:—50 grains of the sample, if possible in fine powder, was allowed to stand an hour with 1 ounce of petroleum spirit, and frequently agitated. It was then boiled for a short time, the solution decanted, and the residue boiled with 10 successive half ounces of petroleum spirit. All the solutions were filtered through a weighed filter, upon which the residue was finally washed and dried at 100° C.

The sulphur was determined by fusing with nitrate of potassium and carbonate of sodium, except in those cases in which the substance would not powder. These were treated with a large excess of pure fuming nitric acid, first at a gentle heat, and afterwards boiled, the solution largely diluted with water, almost neutralized with ammonia, filtered and precipitated with chloride of barium. The sulphur was determined in the part insoluble in petroleum spirit, in one of the Syrian asphalt, and in the ash of Trinidad pitch and Val de Travers asphalt.

The samples examined were three of coal-tar pitch, by three large makers. They vary in the amount soluble in petroleum spirit, owing, no doubt, to the extent to which the distillation was carried. These have a conchoidal fracture, and give a black powder.

Rosin Pitch.—Obtained in the distillation for rosin oils. This has a conchoidal fracture, but gives a brown powder, and is almost entirely soluble.

Stockholm Pitch.—This is a black mass, too soft to powder, and is very soluble.

Stearine Pitch.—A black mass, which will powder with difficulty, not so soluble as the two previous kinds.

Trinidad Pitch.—This is the natural product of the celebrated pitch lake of Trinidad. It is a brown, earthy-looking substance, giving a brown powder. About two-fifths of the organic matter is soluble, and the ash is almost entirely silicious.

Fine Syrian Asphalt.—A natural product, almost black, but giving a dark brown powder.

Low Syrian Asphalt closely resembles the "fine," but contains more earthy matters. These, with the Trinidad pitch, are remarkable for the high percentage of sulphur. The presence of sulphur in natural asphalt has been noticed before. The *Journal of the Chemical Society*, 1879, p. 896, contains an abstract of a paper by O. Helm, in which it is stated that Syrian asphalt contains 9·13 per cent. of sulphur, and a sample of American asphalt 10·85 per cent. The sulphur was almost entirely in combination with the organic matter. These figures are higher than those which I find, but no doubt there are variations. The sulphur was found to be in the fine Syrian 6·13 per cent., of which 3·74 per cent. was in the portion insoluble in petroleum spirit, and 2·39 per cent. in that soluble. The ash of the Trinidad pitch contains ·137 per cent of sulphur.

American Asphalt.—This is evidently a manufactured article, and not a natural product. It is a black, brittle substance with a conchoidal fracture, and gives a black powder. It is soluble to the extent of about two-thirds in petroleum spirit, and is quite different from stearine pitch, both in its appearance, brittleness, and in the percentage of sulphur. I cannot learn the origin of it, but it is shipped from San Francisco.

Val de Travers Asphalt.—This is a limestone, rather magnesian, soaked in a soft bituminous substance, entirely soluble in petroleum spirit. The limestone contains ·15 per cent. of sulphur as sulphate of calcium. The organic matter, therefore, contains only 2·74 per cent. of sulphur. I regret that my application for a sample of Seyssel asphalt was not successful.

Burgundy Pitch.—An examination of the only pitch recognized in the Pharmacopœia was necessary, if only to give this paper a better title to your consideration, but it is a substance of a totally different nature from the others treated of in this communication. It is a resin of a yellow colour, and, although easily pulverized, soon becomes a solid mass at the ordinary temperature of the air.

The accompanying table gives the results of the investigation for comparison:—

Description.	Soluble in Petroleum Spirit.	Insoluble.	Ash.	Sulphur.	Organic matter soluble in P. S.	Organic insoluble in P. S.	Sulphur in organic matter.

I have to acknowledge the valuable assistance rendered by Mr. Arthur Haddock in making many of the analyses.

The President, in proposing a vote of thanks to Mr. Davies, said some of the samples mentioned contained nearly 100 per cent. of organic and combustible matter. Some alarm had been created by the public press within the last six months respecting the relation of asphalt to fire, and it had been suggested that the laying of asphalt, so called, in the streets, and as a roofing for houses, or rather as the external coating of other roofing, was well calculated to set fire to the whole of a city. He feared possibly some support to this motion might be derived from Mr. Davies's research, because there could be no doubt that some of the asphalts to which he had alluded were very combustible. It was, therefore, important to bear in mind that what was known by the public as asphalt, and was used for paving and roofing purposes, was a substance containing something under 10 per cent. of true asphalt, and over 90 per cent. of absolutely incombustible matter, and that in fact it was practically impossible to set light to what was popularly known as asphalt, so that it might of itself continue in a state of combustion. Of course a little reflection by any one who knew the composition of this so-called asphalt would show that there was not the most remote danger connected with its use. No doubt asphalt pure and simple was combustible, and so was gunpowder combustible; but if the latter were mixed with 90 per cent. of sand or other mineral matter it would be exceedingly difficult to set fire to that mixture, and it would be still more difficult to set a light to the mixture of asphalt and mineral matter which was commonly used for paving and roofing.

A vote of thanks was passed.

Mr. Thomas Hugh Williams said some of the remarks which Mr. John Williams had made with regard to white wax, and which might with equal justice have been made with regard to sesame oil, might also be applied to Burgundy pitch. The compound met with in commerce under that name had very little right to be called Burgundy pitch, but was simply a mixture of resin, palm oil, and water, and the figures which had been put forward seemed to him very suggestive of such a mixture.

Mr. Conroy said chemists and druggists would not buy genuine Burgundy pitch, and, as a rule, would only have the fictitious article, which was of a much brighter colour than the genuine; he did not think the public would have it either.

Mr. Holmes said one chemist that he knew had told him he always used Burgundy pitch, but obtained it with difficulty, and his customers preferred it, because it was not so irritating, but had a more beneficial effect. Some years ago, having succeeded in obtaining a small quantity, he took from time to time all he could get of it, having tried in vain to get it from any other wholesale house.

The next paper was a

Contribution to the Pharmacy of the Pomegranate.

BY LOUIS SIEBOLD.

The great value of the root-bark of *Punica granatum* as a remedy for tapeworm is so well established as to need no comment. It is well known, however, that the administration of this drug often results in failure on account of the extremely nauseous astringent taste of its decoction and its consequent rejection by the stomach, a fact which renders it almost useless for ladies and children. The usual way of meeting similar objections in other cases, by substituting the active principles for the crude drug, does not seem to promise well in this instance, owing to the difficulties attending the isolation of these principles in a pure state and their proneness to decomposition (see C. Tanret's researches on pelletierine and the other alkaloids of the pomegranate, abstracted in the 'Year-Book of Pharmacy,' 1878, p. 43; 1879, p. 38; and 1880, p. 64). The question then arises, whether it is possible to produce, by a comparatively simple process, a pharmaceutical preparation of this bark, which, while possessing the full activity of the drug, is at the same time free from the nauseous taste and the unpleasant effects alluded to. Such a preparation, I believe I have succeeded in making. I do not wish to trouble the meeting with the various steps taken in working out the problem, nor with particulars of unsuccessful experiments in the direction indicated, but will at once lay before you the details of the process finally adopted.

Six ounces of the coarsely powdered root-bark are digested three successive times with 48 fluid ounces of water at 160° F., previously acidified with a few drops of acetic acid, each time for about twelve hours, during which the mixture should be frequently agitated and the temperature maintained at or near the point given. The strained infusions, measuring in all nearly 140 fluid ounces, are united, and gradually mixed with solution of sugar of lead until no further precipitate is formed on testing filtered portions; the whole is then filtered, the slight excess of lead removed from the filtrate by a current of washed sulphuretted hydrogen, the mixture warmed for some time to expel the excess of the gas and again filtered, and the perfectly clear liquor evaporated on a water-bath to the consistence of a syrup, at a temperature not exceeding 140° F. Evaporation *in vacuo* would probably be better still; but this I have not tried. Finally the small quantity of residue left is mixed with syrup of orange peel sufficient to produce a draught of about 2 fluid ounces. This draught represents a dose for an adult, and should be taken at once, first thing in the morning, the patient abstaining from food and keeping quiet for about four hours after the administration. A diet of meat and fish, without bread or farinaceous food of any kind, should be observed for the two days preceding the cure, and on the last day no food whatever should be taken after dinner. During this afternoon it is also advisable to clear the bowels by means of a mild purgative; if then the draught be taken at about two or three o'clock the following morning and sleep again resorted to after its administration, the patient will have done all he can to ensure success.

In eight out of nine cases in which the efficacy of this preparation was tested, the entire tapeworm was expelled within five hours after the consumption of the draught, and in one case only success was not complete. The eight cases comprise three of *Tænia solium*, and five of *T. mediocannellata*. In one of the latter instances not the slightest care as regards diet was observed, and, contrary to all instructions, the patient took a heavy supper the night before the administration of the draught, and yet the entire worm was expelled. In all the eight cases various tapeworm remedies had been tried previously, decoction of pomegranate root-bark being also among those employed without success, the head of the worm remaining, although the decoction in the cases alluded to was retained by the patient. It would thus appear that the preparation I have described, in addition to being free from all objectionable taste, may also be superior to the decoction of the bark in point of activity, owing, probably, to the entire absence of astringent principles, the abundant presence of which in the decoction is not unlikely to counteract the effect of the anthelmintic constituents.

The preparation obtained as above has a pleasant fruity flavour and is readily borne by the stomach. The most fastidious patient would take it without the slightest difficulty. The value of such a preparation appears to me the greater from the fact that all tapeworm remedies of repute share the nauseous taste and sickening effects of the decoction of pomegranate bark.

While admitting that the cases in which this new preparation has thus far been put to the test are yet not great in number, I think I am justified by the results in inviting the best attention of medical practitioners on the one hand, and of pharmacists on the other, to this subject. Those who are fully acquainted with the numerous failures in the treatment of cases of tapeworm by even the most renowned remedies, must long since have felt the want of a preparation combining efficacy with freedom from all unpleasant taste.

The President proposed a vote of thanks to Mr. Siebold for this admirable contribution to practical pharmacy. The value of the dose would seem to quite justify the pharmaceutical labour and care necessary for its preparation. It appeared that 6 oz. of material had to be treated with 7 pints of water, then concentrated into a very small quantity and made up to 2 fluid oz. for a dose. He did not see any objection to that, in fact it seemed an opportunity for pharmacists to develop their power; but still he should like to know whether the preparation kept well, or whether it must be prepared whenever it might be wanted.

Dr. Quinlan, having been accustomed to encounter the difficulty of expelling tapeworm, wished to bear testimony to the great value of this paper. There was no more troublesome affection to deal with, and up to the present time the remedy principally relied upon was turpentine, which was disagreeable, and occasionally dangerous, because if not at once eliminated from the system it might produce serious results. The pomegranate bark was an old Spanish remedy, which had rather fallen into disuse, and he was glad to see it revived, and to hear of this method for its preparation. He should immediately try it, and report the result to the medical journals.

Mr. Tanner asked if he understood Mr. Siebold rightly, that the extremely nauseous taste of pomegranate preparations was due to an organic acid.

Mr. Siebold said it was due to tannic and gallic acids.

Mr. Tanner also asked whether the removal of the surplus lead, which was effected by sulphuretted hydrogen, could not be sufficiently effected by some other means, either dilute sulphuric acid or soluble carbonate, because the appliances for using the sulphuretted hydrogen process might not be found in all pharmacies.

Dr. Symes said if it were not verging too much on the medical aspect of the question, he should like to ask Mr. Siebold whether the oil of male fern had been tried in the cases to which he referred. Dr. Quinlan had said the only remedy at their disposal was turpentine, but in his experience oil of male fern was very frequently employed.

Dr. Quinlan said he meant to say that the principal remedy on which physicians could rely was turpentine; they frequently used male fern and other remedies, but turpentine was always sure, and constantly in cases where they had tried other things they had to go back to turpentine.

Mr. Siebold said he was much obliged for the kind offer of Dr. Quinlan and should eagerly look forward to the result of his trials. As regards the time the preparation would keep, he had noticed no deterioration in the course of two months, but he had no experience as to how much longer it could be kept without injury. In the case he had mentioned all the usual tape-worm remedies had been unsuccessfully tried, oil of male fern among the number. He could not recommend the use of sulphuric acid in the place of sulphuretted hydrogen, for the removal of the lead, as any excess of this acid would, during the subsequent evaporation, injuriously affect the activity of the preparation, for this he had found in the course of his experiments to be the result of long continued heating in the presence of mineral acids. He was quite aware that the directions he had given were rather too tedious to allow of the preparation being made from a physician's prescription in the ordinary course of business; but he should like to see a wholesale house of repute undertake to produce the preparation on a large scale for the supply of dispensing establishments.

The next paper was on—

Scammony—a Novel Adulterant.

BY MICHAEL CONROY, F.C.S.

Perhaps no drug contained in the materia medica has received so much attention from dishonest dealers as scammony, but the adulteration hitherto practised has been so clumsily and ignorantly effected, and the articles used for the purpose have been so simple, that a few easy tests have sufficed for their detection. Among these tests the one mostly relied upon, is the extraction and estimation of the resin by means of ether. No longer, however, will the test be so simple, for a genius has arisen in the East who has found a plan of producing the gum otherwise than by the poetical manner of collecting the milky juice in mussel shells, so ably described by Mr. Maltass, of Smyrna. This scammony may not be of the same therapeutic value as that known to Theophrastus in the third century B.C., nor as that described by Hippocrates or Dioscorides, nor yet as what Helias, patriach of Jerusalem, sent to our king, Alfred the Great, but still it is not as bad as many other samples to be found in the market.

This sample which represented a direct importation from Constantinople, came into my hands a few days ago for the purpose of analysis. It consisted of several small pieces which had apparently been broken off large thick cakes, with the object of obtaining a representative specimen of the bulk, from which they were taken. These were of a uniformly dark ash-grey colour, breaking easily and presenting a resinous, shiny black fracture, indistinguishable from pure virgin gum. Triturated in a mortar the pieces were easily reduced to a buff coloured powder, somewhat darker than what is usually obtained from the virgin gum. This powder formed a very nice emulsion with water, and in other respects appeared quite satisfactory. To ether it yielded 83·8 per cent. of a nice amber-brown resin, and a decoction of the residue when cooled was turned blue by iodine, as is usually the case with nearly all commercial specimens. The starch thus indicated was found by the microscope to be wheaten. So far nothing arose to create suspicion, but on examining the resin obtained by the extraction with ether, I was at once struck by its peculiar smell, which recalled the odour of the resin prepared from the root by means of alcohol, pharmaceutically known as scammony resin. This caused me to powder another portion of the sample, which on comparison with a sample of true virgin powder, at once revealed the presence of the resin prepared from the root. There is no mistaking the distinctive odour of this resin, and its presence will reveal itself by its very peculiar and persistent leathery odour, while the true gum possesses quite as distinctive a sour, cheese-like odour; and there is no doubt that this parcel has been made up of some skillip scammony and resin prepared from the root. It is the first time that I have met with this adulterant, and since my examination of the parcel I have learned that though containing 83·8 per cent. of resin, it was offered at four or five shillings below the market value of virgin gum. Samples are on the table of both the gum and powder, together with a sample of true virgin powder for comparison.

A vote of thanks was passed to Mr. Conroy.

A paper was then read entitled—

Aconitine for Internal Administration.

BY T. B. GROVES.

From a perusal of an article "Preparations of Aconite," in No. 5, vol. i., of Dr. Squibb's *Ephemeris*, it would appear that aconite plays a more important part in medication on the other side of the Atlantic than it does in this country. Here the admitted uncertainty of action both in degree and kind of the official preparations of the drug seems to have had the effect of dismissing both drug and preparations from the medical armoury: there, on the contrary, this feeling serves but to stimulate research with the view of providing for medical practitioners a trustworthy preparation of a drug of admittedly high value. Pharmacists cannot but feel greatly indebted to Dr. Squibb for his able article on the subject, although his conclusions may not meet with universal acceptance. In fact, it seems to me that to decide, after all the labour that has been expended on the chemistry of the aconite alkaloids by Wright, Duquesnel, and others, on recommending for internal use a fluid extract of a root that varies so greatly in activity, is a distinct retrogression in pharmacy tending to render useless a vast amount of original research conducted with unusual care and completeness. It is true that Dr. Squibb has indicated a method of estimating by the sense of taste the quality of the root, but such a method, crude in extreme as it must be in any case, would be unable to distinguish between roots differing widely in their chemistry and physiology, like *A. Napellus* and *A. ferox*. In fact, the latter, owing to the less amount of acrid resin it contains, would give a less marked result than its less potent congener. It is not pretended that the subject has been exhausted. New varieties of root have from time to time made their appearance in the market, and though the chemist has essayed to perform his part in their examination, he has not been adequately seconded by the experimental physiologist. The legal difficulties in the path of inquiry in this direction may well account for the apparent and probably only apparent lack of interest among the medical profession in a class of remedies so potent for good or evil as the various alkaloids of the genus *Aconitum*.

Practically we may, I think, limit our attention to one species only of the toxic aconites. *A. Napellus* is that which has, I believe, been invariably ordered in the manufacture of what may be termed crude aconite preparations for internal use, and it is to it that the textbooks refer when treating of the physiological properties of aconite. Its alkaloid, nap-aconitine, has been examined and described by several experimenters, so that its identification when in a pure crystalline condition is comparatively easy. Moreover, its precise physiological action has been studied by Dr. Fraser, of Edinburgh, who compared its action with that of fer-aconitine (the so-called pseudaconitine of Von Schroff) who reported thereon to the British Association at the Bradford meeting in 1873. His results, which are given in short abstract in the Annual Report, point to the necessity of discriminating between the two alkaloids when used for internal administration. But can they be with certainty discriminated? Undoubtedly, and it is the more necessary to take precautions in this direction, owing to the fact which Wright has pointed out that *Aconitum Napellus* yields both nap-aconitine and fer-aconitine, the latter in very small proportion it is true but still enough to modify in a sensible degree the action of its companion alkaloid. That the more powerful *A. ferox* has frequently (probably as often as procurable) been employed for the extraction of commercial aconitine is unquestionable. The element of uncertainty thus introduced has perhaps had much to do with the neglect with which English practitioners have treated aconitine as an internal remedy; a neglect which is seen to be fully justified when it can be shown that of the commercial aconitines so-called many are wholly amorphous and therefore indefinite in character, whilst others are not only so, but are also contaminated with aconite alkaloids without toxic properties, and of little physiological activity of any kind.

Mr. Cleaver has pointed out the source of one such possible contaminant in *A. paniculatum*, which he states yields an inert alkaloid identical with that provisionally named picraconitine, which I extracted in quantity from a batch of so-called *A. Napellus*. I at first supposed it to be identical with atisine, the alkaloid of *A. heterophyllum*, but I was assured by Dr. Broughton, who saw my specimens, that such was not the case, an opinion afterwards borne out by the results of combustions carried out in the laboratory of Dr. Wright.

I would recommend to anyone setting about the preparation of nap-aconitine for internal administration to be very careful in the selection of his roots. If possible, they should be grown in this country, with guarantee from the grower that they are the produce of *A. Napellus*. Mr. Holmes will soon, I hope, be able to tell us more about the numerous varieties of this plant and their relative degrees of toxicity.

To him we also hopefully look for showing us how to recognize them by optical means, microscopic or otherwise, as well as how to distinguish between the dried roots of *A. Napellus* and *A. paniculatum*.

Having obtained by following Stas' general method of extraction the crude alkaloids of presumably true roots, the aconitine before it can be safely used for internal exhibition must be separated in a crystalline condition. This is not difficult, but it is wasteful, if such a term can be permitted in this connection. Ordinary skill only is required, helped by extraordinary patience. As I pointed out so long ago as 1866, the nitrate is the best of its salts to crystallize, a fact I had demonstrated two years previously. I have never failed in producing it in quantity averaging, perhaps, one third of the total yield of alkaloid. From the nitrate the pure alkaloid or any of its salts can be made without difficulty.

It fortunately happens that the nitrate of fer-aconitine is crystallizable only from a strongly acid solution. It is therefore necessarily excluded from the crop of crystals obtained from a neutral or nearly neutral liquid.

There remains the possible admixture of picraconitine, the nitrate of which crystallizes in forms so like those of nap-aconitine that by an ordinary observer they would not be distinguishable. Its bitterness is its most patent distinction. The poisonous aconitines are much less bitter. Moreover, its comparative solubility in dilute ammonia is characteristic; so that a nitrate of aconitine that yielded on precipitation with dilute ammonia a proportion of alkaloid much less than that due to its centesimal composition would deservedly be suspected. However, the best test of all would be the physiological applied to each batch of alkaloid by a competent experimenter, and were a series of preparations so guaranteed produced by a house of known reputation, I am confident that in the course of a short time they would be accepted by the medical profession as a valuable addition to the list of heroic remedies.

The PRESIDENT having moved a vote of thanks to Mr. Groves for this last contribution of his to the literature of aconite,

Dr. WRIGHT said he could only regret the retrogressive action of the American Pharmacopœia Committee on this question. Some two or three years ago, while the revision was in progress, he was applied to by Dr. Rice, the Chairman of the Committee, to draw up a kind of *précis* of the general chemical and physical characteristics of the various aconite alkaloids as far as then known, and he was in hopes that the information then extant would have sufficed to have convinced the Committee that there was quite a possibility and practicability of having one uniform alkaloidal preparation which might be prescribed, instead of an uncertain tincture such as was ultimately adopted. With reference to another point, that the nitrate of aconitine was a convenient sort of preparation, he should say that the hydrobromide was almost as convenient for various purposes, especially considering its sparing solubility, and was not open to an objection which nitric acid was open to, that a certain amount of decomposition rendered further purification necessary. He believed Dr. Stevenson was carrying out some investigations with regard to the physiological character of the various alkaloids, for at the time of the Lamson trial he supplied him with samples for the purpose, and he hoped that before long he would afford some valuable light on that subject.

Mr. WILLIAMS said he could hardly say much at so late an hour on this subject; but he was rather bound up to a form of this alkaloid, namely, the amorphous form, which had been prepared and used medicinally for upwards of fifty years, and with which he had been more or less connected through the late Mr. Morson. He could hardly agree with Mr. Groves, that they ought to change the form and go to a crystallized article, his own belief being that a crystallized aconitine was not physiologically so active as the aconitine produced or discovered many years ago by Dr. Turnbull. He could hardly give any opinion on Mr. Groves's suggestion, except to say that it was not in accordance with his present views.

(*To be continued.*)

Parliamentary and Law Proceedings.

PROSECUTION UNDER THE 17TH SECTION OF THE PHARMACY ACT.

At the Birmingham Police Court, on November 8, before Mr. T. C. S. Kynnersley, Stipendiary, Matthew Wheatley, drysalter, etc., of 142, Sand Pits, Birmingham, was charged with having sold on the 30th ult., to Alfred Short Wright, Assistant Secretary to the Chemists and Druggists' Trade Association of Great Britain, a certain poison, to wit, 1 drachm of laudanum (the same being a preparation of opium), not being distinctly labelled with the name of the article, and the name and address of the seller of the same, contrary to the statute in such case made and provided.

Mr. Henry Glaisyer, Solicitor to the Chemists and Druggists' Trade Association, who appeared for the prosecution, said the summons was issued under the 17th section of the Pharmacy Act, which made it unlawful to sell any poison either by wholesale or by retail unless the box, bottle, vessel, wrapper or cover in which such poison was contained be distinctly labelled with the name of the article and the word "poison" and with the name and address of the seller of the poison. The defendant in the case was Mr. Matthew Wheatley, a drysalter, who carried on business at 142, Sand Pits and King Edward's Road, who had no business whatever to sell poisons scheduled under the Act. The Secretary of the Chemists and Druggists' Trade Association, Mr. Wright, visited the defendant's shop on October 30 last, and purchased from a boy behind the counter one pennyworth of laudanum; he took a bottle with him, and the only label the boy put on the bottle contained the word "poison." The name of the poison was not mentioned, nor the name or address of the defendant.

Mr. Alfred Wright being called and sworn, gave evidence in support of the opening statement.

The Stipendiary, addressing the defendant: Have you any reasonable defence to offer?

The defendant: We do not keep laudanum in stock for sale at all; I use it sometimes for neuralgia. The boy had no business whatever to sell it.

The defendant was fined 20*s.* and costs.

Poisoning in a Hospital by Carbolic Acid.

Mr. F. Price held an inquiry on the 8th inst., into the death of Richard Schofield, who met his death from poisoning by carbolic acid, on the 5th instant, at Monsall Hospital, Newton Heath.

Sarah Schofield, wife of the deceased, said he entered the hospital on Sunday fortnight suffering from scarlet fever. She did see him alive afterwards.

Fanny Gilchrist, head nurse, said deceased was a patient under her charge. The medicine was prescribed by Dr. Tomkins, and was sent up from the surgery from the dispenser, and placed in the medicine cupboard prepared for the purpose in the lobby of the hospital. Carbolic acid was not usually kept there, but it got there sometimes after being used for disinfecting purposes. Such bottles were always labelled "Poison," and were very plain. The bottles were the same size, form and colour as the medicine bottle, except a few which were fluted. Deceased was under treatment and recovering rapidly, and able to go about up to the 4th inst. About nine o'clock on Sunday evening she told the nurse to give the deceased a dose of his medicine, and directly afterwards the nurse met her, when she looked at the bottle and found it was carbolic acid. She said, "You have not given him this?" She replied "Yes." She went immediately for Dr. Tomkins and told him. The gas was at full light opposite the cupboard from which the carbolic acid was taken.

Dr. Tomkins deposed to visiting deceased and applying the usual remedies. He was coughing slightly, and his breath had the odour of carbolic acid. The stomach pump brought back the acid, and afterwards the deceased recovered consciousness and seemed to get better. He sank on the following evening and died at ten o'clock on Monday night. It was a standing rule that no strong preparations of any kind should be kept in the medicine cupboard, there being a place specially appointed for them. The nurse in question was a probationer, and had only been three weeks in the employment. She had only given medicine two or three times before.

The Jury returned a verdict of "Death from misadventure by carbolic poison," and recommended a heavy censure of the hospital officials.

The Foreman said they would be very sorry to put the girl on her trial for manslaughter, but the case was so serious that it almost merited it. It was certainly necessary that in an institution where people were sent to be specially cared for they should not be subjected to such carelessness as that which had occurred.

The Coroner then censured the officials, and said the jury had taken a merciful view of the case. It was doubtful whether they would not be doing their duty in sending the two nurses to the assizes for causing the death of the deceased by manslaughter. The police might take a different view from the jury, and it might be that they would yet have to appear before the magistrates on a grave charge. The medical officer promised to take greater care in the future in respect to poisons, and said they would be locked up in a separate chest.—*Manchester Courier.*

Attempted Suicide.

At Plymouth, on Monday, Thomas Francis, a fisherman, was charged before the Plymouth bench with attempting to commit suicide on Thursday, by taking poison. About eight o'clock on Thursday evening prisoner went to Mr. Adams, chemist, Exeter Street, and asked for some poison to kill rats on board his master's boat. Mr. Adams put to him several questions which he satisfactorily answered. He was, therefore, served with a threepenny packet of vermin killer, and signed his name in a book. About half-past ten he was in the Fisherman's Rest drinking, and then told his niece that he had taken poison. She did not pay much attention to him, and when he left the house he fell down on the pavement. He was carried to the hospital and attended by Mr. Carter, the house surgeon. Prisoner was conscious, but unable to walk, and complained of pains in his head and stomach. He was placed in bed, and about the middle of the night exhibited symptoms of strychnine poisoning. He was very ill on Friday, but recovered on Saturday.

Prisoner said he was drunk on Thursday, and did not know what he had done. He was remanded for a week. —*Western Morning News.*

Poisoning by Carbolic Acid.—A Coroner's Opinion as to a Chemist's Duty.

The Plymouth Coroner (Mr. T. C. Brian) held an inquest on the 12th inst. relative to the death of Amelia Heathershire, a married woman, who died from taking poison, at the Hospital, on Saturday afternoon.

Silas Robert Lillicrap, landlord of the Royal Exchange Inn, Vauxhall Street, stated that he knew the deceased. About 2.30 p.m. on Saturday she came into his bar sober and looking well, and asked for "a drop of gin." She had a basket with her and took a small bottle from it. It was a green glass bottle, and on the label was printed the words "A lotion." She replaced the bottle in the basket. Witness went upstairs and was absent about five minutes. When he returned to the bar deceased gave him the glass, and he remarked that it smelt of tar. The woman replied, "It is nothing, it is all right." Witness then went to the brewhouse, and on returning found deceased lying on the floor speechless. Mr. Adams, chemist, was sent for, and advised her removal to the hospital.

Mr. William Adams, chemist, 141, Exeter Street, stated that between noon and one p.m. on Saturday deceased came to him. She smelt of drink, and asked for a small quantity of laudanum to make her sleep as she was in trouble. She seemed distressed and pressed much to have the laudanum. She said she knew how to take it, as she had lived with a doctor who was accustomed to use it, and witness need not be afraid of what she would do with it. Witness said he thought she had been drinking. She replied that she had not taken anything for three months, adding that her daughter had given her a great deal of trouble. Witness told her he could not supply her with laudanum and he did not think any other chemist would. She then said that she was determined to destroy herself, and would get laudanum somewhere, even if she got a pennyworth at a time. Between three and four o'clock he was called to the Royal Exchange Inn, and on going there recognized the deceased, who smelt of carbolic acid. He saw that she was in a state of collapse, and was dying.

Mr. Edw. Maclachlan, assistant to Messrs. Balkwill and Co., chemists, Old Town Street, deposed to the deceased coming into their shop about two o'clock and asking for twopennyworth of carbolic acid for using upon bedsteads. She said she knew it was poison. Witness supplied her with the acid in a bottle (produced), which she had with her. He labelled it as poison. She appeared quite sensible, but on leaving the shop was unsteady in her walk.

Dr. G. Carter, house surgeon of the South Devon and East Cornwall Hospital, stated that when deceased was brought to the institution she was quite unconscious and almost pulseless. He gave her the usual antidotes for carbolic acid, and used the stomach pump. She expired at five o'clock the same afternoon. After death the bottle and two pawn-tickets were found in her clothing by the nurse. The cause of death was poisoning by carbolic acid. Dr. Carter said he did not believe carbolic acid was scheduled among the poisons mentioned in the Act of Parliament.

Mr. Balkwill, who was present, desired to give evidence, and stated that he was present in the shop when deceased came in, and heard her ask for something to poison bugs. She said she had tried everything to get rid of them, but quite ineffectually. As she went out of the door she staggered a little. Mr. Maclachlan asked him whether he thought he had done right in serving her with the carbolic acid. Witness thought that after her explanation he was quite justified in supplying the woman. Carbolic acid was not scheduled as a poison, and the bottles it was sold in were not a'l blue fluted, as those for other poisons were.

The Coroner said that no doubt deceased had a feeling of regret and remorse at having returned to her drinking habits, and, moreover, she was annoyed at the marriage of her daughter. Credit was due to Mr. Adams for not allowing the woman to buy any laudanum. There was no doubt that when he refused to supply her with laudanum she went in a bold manner to Mr. Balkwill's. He thought that when deceased told Mr. Adams she was determined to take her life, he should not have let her leave the shop so easily.

A Juror said it was the opinion of several members that the Coroner had spoken too severely of Mr. Adams. They thought he had acted discreetly and kindly towards the deceased.

The Coroner remarked that he would take care that anyone who threatened in his presence to commit suicide should not leave his presence so easily.

The Jury returned a verdict "That deceased committed suicide whilst in a state of temporary insanity," and exonerated the chemists from all blame.—*Western Morning News.*

Poisoning by Phosphor Paste.

On Tuesday Mr. W. J. Payne, City Coroner, held an inquiry at the Coroner's Court, Golden Lane, regarding the death of Joseph Holloway, aged 47, who committed suicide by taking a quantity of phosphorus paste. The deceased was a coffee-housekeeper. For some time past he had been very much depressed, as a young lady, with whom he was acquainted, had threatened to institute proceedings against him for breach of promise of marriage. As his business had fallen off very much lately, he greatly feared that the action would ruin him, and he had expressed himself to that effect. On Wednesday last the case was tried in the Court of Queen's Bench, and a verdict was given for the plaintiff, but for nominal damages only and no costs. The deceased was very much pleased with the result, but told his sister that before the trial came on he, fearing the result, had taken a quantity of phosphorus. He, however, did not appear to be ill, but on Thursday last he complained of pains about the body, and a medical man was called in. The deceased attempted to hang himself a short time before the trial came off.

Dr. Adams said he was called to attend the deceased, who was suffering from the effects of poison, and that he had taken some phosphorus paste. He died on Saturday last from the effects of the poison. He informed witness that he had taken it the day before the trial came off. Several days would elapse before the poison would take effect.

The Jury returned a verdict to the effect "That deceased committed suicide while suffering from temporary insanity."—*Times.*

Tincture of Nux Vomica prepared from the Extract.

Sir,—As the experience of Mr. Hick in the preparation of tincture of nux vomica from the extract appears to differ somewhat from mine, I shall feel obliged if you will allow me to say a few words in extension of the remarks I made in the discussion following the reading of Messrs. Dunstan and Short's excellent "Report on the Pharmaceutical Preparations of Nux Vomica," to which your correspondent refers.

It is now fourteen or fifteen years since I tried this process and abandoned it for the reasons stated. Further, I consider it bad pharmaceutical practice to prepare a tincture by solution of the extract, when it can be prepared with equal facility from the crude drug, for it must be within the experience of all practical pharmacists that no extract will again perfectly dissolve in the menstruum by which it was extracted; the heat and exposure necessary for evaporation having wrought some change in it, usually of a detrimental character. Your correspondent admits that about one-twenty-fourth part remains undissolved, and this in the recently prepared tincture; but he does not state what amount is subsequently deposited on the bottom and sides of the containing vessel. His plea that greater uniformity is secured by the use of the extract is, I think, scarcely tenable, for this and other reasons presently to be stated. I will now pass on to the consideration of the formula with which he proposes to replace that given in the B.P., and at the outset would warn those pharmacists who may feel disposed to adopt it, that the result will be a preparation having certainly less than half the strength of a carefully made B.P. tincture. Mr. Hick does not give the data from which he arrived at the result that a solution of 3 grains of ext. nuc. vom. in 1 fluid ounce of spirit represents tinct. nuc. vom., B.P., nor does he tell us whether a tincture so prepared has the greenish-yellow colour that a well prepared tincture should have. On referring to my notes of this drug, I find that nux vomica yields on an average 15 per cent. of extract in a hard and dry condition, representing, probably, 20 per cent. or more of the extract, as usually sent out by wholesale houses (Mr. Hick does not tell us the condition of the extract he uses, nor whether he prepares it himself). A simple calculation will show that on this datum 1 fluid ounce of B.P. tincture should contain something like 7 grains of hard extract, and not 3 grains as your correspondent seems to think; a sufficiently alarming discrepancy, I think, to guard one against the substitution of one formula for the other. An actual experiment made by evaporating to dryness at 100° C. 1 fluid ounce of B.P. tincture gave $6\frac{1}{2}$ grains of extract, or more than double the quantity he proposes to use.

I am surprised to hear, and doubtless others will be also, that "the B.P. formula is so troublesome that few retail chemists make their own tinct. nux vom.;" let us hope it is not true.

Tottenham High Cross. A. G. Tanner.

Ignoramus.—The spirit could be recovered by distillation.

Chemicus.—Apply to the Registrar under the Dental Act, 299, Oxford Street, W.

Minor.—We believe the business is fairly prosperous in the colony mentioned. The English Minor qualification entitles the holder to registration without further examination in all British colonies where at present Pharmacy Acts are in force.

A. B.—You will find the recipe you require and some remarks concerning it in the *Pharm. Journal* for April 28 last, p. 884, and May 17, p. 936.

Communications, Letters, etc., have been received from Messrs. Proctor, Landerer, Bennett, Saul, Waldheim, Wells, Samuelson, Apprentice.

RECENT DONATIONS TO THE MUSEUM OF THE PHARMACEUTICAL SOCIETY.

BY E. M. HOLMES, F.L.S.,

Curator of the Museum of the Pharmaceutical Society.

I. VEGETABLE TALLOW FROM SINGAPORE.

Mr. R. Jamie of Singapore, in a letter accompanying some interesting donations lately presented by him to the Museum, has called my attention to this substance as possessing the valuable property of not readily turning rancid. He remarks concerning it—"The vegetable tallow never turns acid, and when the white kind is got, which is seldom, it makes very good ointment, simply with the addition of olive oil." At the ordinary temperature this tallow is a white friable solid, softening into a pasty condition when rubbed between the fingers and ultimately melting sufficiently to be rubbed in without leaving the hand very greasy. It has a very slight nutty odour and taste. It would seem therefore to be peculiarly suitable for camphor balls, suppositories and pessaries; for the latter its slowness in melting seems to peculiarly fit it.

Mr. E. Fielding at my request has made a few preliminary experiments as to its melting point and solubility in various solvents. He reports as follows: "At 65° F. it remains a little solid; between 82° and 104° F. it has the consistence of flour paste; it fuses at about 118° F., but remains transparent and liquid at 112° F. It is soluble in about an equal weight of cold ether; it is sparingly soluble in cold acetic ether and acetone, but very soluble in these liquids when heated, the greater part being precipitated on cooling; it dissolves in half its weight of cold chloroform, but mixes with one third of its weight of the same liquid when heated. In bisulphide of carbon, either cold or hot, it is extremely soluble. In cold benzol it is soluble to the extent of about 1 in 4. In hot benzol and petroleum spirit (hexane or heptane) it dissolves in all proportions, but the solution gelatinizes on cooling. It is very soluble in cold turpentine and dissolves in it when heated in all proportions. In alcohol it is soluble to the extent of about 1 in 30 when cold or 1 in 20 when hot, and in isopropyl alcohol it dissolves to the extent of about 1 part in 25 when cold, and 1 part in 4 when hot." Mr. Fielding thinks it may be compared in many respects with the fat of *Pentadesma butyracea* (*Clusiaceæ*), which should, however, judging from its natural order, be more nearly allied to kokum butter (*Garcinia purpurea*).

According to a cutting from the *Java Bode* newspaper, sent to me by Mr. Jamie, the vegetable tallow, known as Minyak Tangkawang, or Minyak Sangkawang, is obtained from the seeds of one or more trees of the genus *Hopea*, found in the S. and E. division of Borneo, chiefly in the neighbourhood of Qualla Kapuas, and on the west coast in the districts of Sambas and Mampawa. The Dyaks call the fat Kakawang and the tree which yields it Upu Kakawang. This tree is one of the giants of the forest. Several species of the genus appear to be used. Of these *Hopea splendida*, the Tongkawang Tonggul, is also called by the natives Dammar Tangkawang (because the bark yields a dammar ?). The timber is used by the Dyaks for making their prahus, as it is proof against the influence of water. The bark also yields a red dye. This tree grows on alluvial fat clayey ground on the banks of great rivers. *Hopea aspera* grows on the higher mountain tracts, principally on the declivities of Mampawa, and is distinguished by the hairiness of the stems.

The preparation of the fat is very simple. When the ripe fruit falls on the ground, it is collected and allowed to germinate a little in a moist place. It is then dried in the sun until it becomes brittle. The fruit is then deprived of its shell and put into a rattan or bamboo basket suspended over boiling water. When it has been well steamed, the fruit becomes soft and plastic like dough. The fat is then expressed by squeezing the doughy mass in a cloth and is poured into joints of bamboos, by which it receives the cylindrical form in which it is met with in commerce. Some Dyak tribes press the fruit by means of two beams. But it is probable that by neither of these processes is all the fat obtained.

The trees begin to yield when they are about eight or ten years old and the crops are somewhat irregular, but every four or five years an extraordinarily large crop may be counted upon, the fruit being ripe in December and January. According to 'Spon's Encyclopædia' (p. 1413), about ten species of *Hopea*, yielding oil seeds differing much in size, are recognized by the natives of Borneo, three of these being common in Sarawak. The fat is also prepared in Java and Sumatra. By the natives the tallow is used for culinary and lighting purposes.

Although the tallow has not as yet been turned to account in pharmacy in this country, there is no reason why its fitness for medical purposes should not be experimented upon, the fat being a regular article of commerce. As far back as 1856, 651,586 kilos were imported into Singapore, and now several thousands of piculs go yearly to Singapore and are exported thence to England for use as a lubricating agent. For this purpose it has proved most valuable, especially for steam machinery, far surpassing even olive oil. In Manilla it has been employed in the manufacture of candles and found to be very valuable for this purpose. There are doubtless many other purposes in the arts to which the fat might be applied. It contains glycerine and about 95 per cent. of saponifiable matter which has less oleine in it than animal fat. The tree is certainly also worthy of the attention of colonial planters since it yields fat, dye, timber and probably also resin, and the demand for the fat alone, when it is better known and prepared in a pure state, will probably far exceed the native supply.

THE NEW PHARMACOPŒIAS FOR THE UNITED STATES AND GERMANY.

(*Continued from p.* 383.)

Strychnia and its Salts.—There is but little agreement in the German, United States and British Pharmacopœias respecting these compounds. The B.P. includes strychnine only; the U.S.P. includes strychnine and its sulphate; and the P.G. has dismissed the alkaloid and retained its nitrate. The description of the alkaloid in the U.S.P. corresponds to that in the B.P.; the descriptions of the two salts are as follows:—

Strychninæ Sulphas ($(C_{21}H_{22}N_2O_2)_2H_2SO_4 \cdot 7H_2O$), U.S.P.—"Colourless or white shining prismatic crystals, efflorescent in dry air, odourless, but having an intensely bitter taste, which is still perceptible in highly dilute (1 in 700,000) solution, and of a neutral reaction." Soluble in 10 parts of water or in 60 parts of alcohol at 15° C., in 2 parts of boiling water, or in 2 parts of boiling alcohol; soluble also in 26 parts of glycerine, but insoluble in ether. This salt on account of its great relative solubility in water is no doubt convenient for some purposes; it has been pointed out, however, that the same object may be attained by the use of a minute quantity of acetic acid with the alkaloid. The salt ordered is the neutral sulphate, but it has been stated that sulphate of strychnine of continental manufacture is usually an acid salt; as, however, this crystallizes with only two molecules of water, the proportion of alkaloid (70 per cent.) would not be very widely different from the proportion (75 per cent.) in a neutral sulphate with seven molecules. However, it has been variously asserted that the neutral sulphate crystallizes with only five or six molecules of water.

Strychninum nitricum, P.G.—"Crystalline needles, colourless and very bitter. Soluble in 90 parts of cold water, in 3 parts of boiling water, also in 70 parts of cold or 5 parts of boiling spirit."

SULPHUR.—In addition to precipitated and sublimed sulphur, the U.S.P. and P.G. include "washed sulphur." Iodide of sulphur has been omitted from the P.G., but is retained in the U.S.P.

THYMOL ($C_{10}H_{13}HO$), U.S.P. (new); THYMOLUM, P.G. (new).—This antiseptic compound has been introduced into both the new pharmacopœias. The U.S.P. describes it as occurring in large crystals of the hexagonal system, nearly or quite colourless, having an aromatic thyme-like odour, a pungent aromatic taste, with a very slight caustic effect upon the lips and a neutral reaction, and liquefying with camphor. Soluble in about 1200 parts of water, or 1 of alcohol at 15° C., in 900 parts of boiling water, and freely in ether, chloroform, benzol, benzin, glacial acetic acid, fixed and volatile oils and boiling alcohol. Sp. gr. 1·028 as a solid, but lighter than water when melted. Melts at about 50° C., and boils at about 230° C. Mixed with half its volume of glacial acetic acid and then with an equal or somewhat greater volume of sulphuric acid, and gently heated it gives a bright reddish-violet colour. Freedom from carbolic acid is indicated by water saturated with thymol not giving a blue colour with solution of ferric chloride. The P.G. says in addition that it is soluble in 2 parts liquor sodæ (sp. gr. 1·160). Dissolved in 4 parts of sulphuric acid it forms a yellowish liquid that becomes a beautiful rose colour when gently warmed. If this solution be poured into ten volumes of water and digested with excess of white lead, the filtrate is coloured a beautiful violet blue by a small quantity of ferric chloride. Bromine vapour passed through an aqueous solution throws down a white sediment.

VERATRINE.—According to the description in the B.P., "pale grey, amorphous;" in the U.S.P., "a white or greyish-white amorphous, rarely crystalline powder;" in the P.G., "pulvis albus, laxus." In addition to the solubilities given in the B.P., the U.S.P. says it is soluble in 2 parts of chloroform, in 96 parts of glycerine and in 56 parts of olive oil. Some colour tests for its recognition are also given. With nitric acid it forms a yellow solution; with sulphuric acid it first assumes a yellow colour, with a greenish fluorescence, then becomes intensely scarlet, and eventually violet. Heated with hydrochloric acid it dissolves with a blood colour. The P.G. adds that if a solution of veratrine be spread in a thin layer and powdered sugar sprinkled on it the colour is first yellow, then green, afterwards blue, and at the end of an hour begins to disappear. The U.S.P. speaks of veratrine as "an alkaloid or mixture of alkaloids," and this agrees with the statement of Bosetti (*Pharm. Journ.*, [3], xiii., 799) that commercial veratrine is a mixture of cevadine and veratridine.

ZINC.—Of the compounds of zinc the acetas, chloride, oxide and sulphate are common to the B.P., P.G. and U.S.P. The P.G. has omitted the ferrocyanide and lactate, which are not in the B.P., and the valerianate which is, but is alone in retaining the sulphocarbolate and a crude oxide. The U.S.P. has included the bromide, iodide and phosphide, which are not in the B.P. or P.G. The following are the principal characters of the zinc salts not in the B.P.:—

Zinci Bromidum, U.S.P. (new).—White or nearly white, very deliquescent, odourless granular powder, having a sharp, saline and metallic taste and neutral reaction. Very soluble in water and in alcohol. Strongly heated it fuses and then volatilizes with partial decomposition. It is not quite obvious why this salt has been made official.

Zinci Iodidum, U.S.P. (new).—The physical characters of this salt are identical with those of the preceding.

Zinci Phosphidum (Zn_3P_2), U.S.P. (new).—Minutely crystalline friable fragments, having a metallic lustre on the fractured surfaces, or a greyish-black powder, permanent in the air, having a faint odour and taste of phosphorus; insoluble in water or alcohol, but completely soluble in hydrochloric or sulphuric acids, with evolution of phosphoretted hydrogen. This salt has been recommended as a convenient medium for the administration of phosphorus, and it has been included in the non-official lists issued by the Paris and Dutch Societies. But it has been pointed out that it is advisable to commence with very small doses, not exceeding one-twentieth of a grain of the phosphide.

Zincum Sulphocarbolicum, P.G.—Colourless, transparent prisms or tables, easily soluble in 2 parts of water or alcohol, and forming a faintly acid liquid, which is coloured violet by ferric chloride.

NOTE ON AN ANILINE DYE ADULTERATED WITH SUGAR.*

BY H. C. DRAPER.

A sample of magenta dye, purchased from an English firm, was found to contain crystalline matter insoluble in alcohol. The writer, on examination of the bulk of the dye, found that, mixed with the characteristic crystals of rosaniline chloride, was a large number of small cubes of a darker colour. These on further examination proved to be crystals of *sugar* "faced" with roseïne, and many of them so slightly coated that the dye was easily removed by rubbing them with the fingers. As the sugar crystals could be readily distinguished by inspection, they were picked out by hand from a weighed quantity of 10 grams, and it was found that they amounted to no less than 75 per cent. of the whole.

A fresh quantity of 10 grams of the dye exhausted with absolute alcohol left a sugar residue equal to 59·5 per cent.

It would be interesting to know to what extent this somewhat ingenious form of adulteration is carried.

ESTABLISHMENT OF PHARMACEUTICAL COURTS OF HONOUR IN GERMANY.

Seventeen years have now elapsed since, in a paper read before the Pharmaceutical Conference at Nottingham, Mr. Ince dealt with the ethics of pharmacy in a way that at the time attracted considerable attention and gave rise to much subsequent discussion. One section of that paper was devoted to the subject of the behaviour of the pharmacist with regard to those in the same line of business as himself and was pervaded by the sound common sense which constitutes one phase of true wisdom as well as by the charity which "is not easily provoked, thinketh no evil." That essay still preserves some vitality, notwithstanding the journalistic mountain that has been piled upon it since its production, for it is still sometimes referred to, although probably very seldom read; the latter is, however, a fact to be regretted, for had the spirit of the counsel given in it a more frequent opportunity of becoming diffused, we might be spared the task of reading every year yards of depressing manuscript, in which pharmacists sometimes formulate charges against their competing brethren as dark as the ink in which they are written. We are far, however, from saying that such charges are always without foundation; for, unfortunately, now-a-days the competition involved in the struggle for existence is so keen that the ethical sense is in danger of becoming dulled, and a man's capacity of judging as to his duty towards his neighbour is apt to show signs of being impaired. It is not so very long ago that an eminent pharmacist who, some years previously, had read an admirable paper on the subject before an important pharmaceutical association, was expelled from the same association for a breach of pharmaceutical ethics. But similar grievances appear to exist also in places where such an explanation could not be put forward; for they occur even in Germany, where at least pure pharmacy is supposed, comparatively, to be protected by the State from the rough winds of competition. However this may be, the subject has now been long under consideration of the leading pharmacists of that country, and at a convention of delegates held in connection with the recent annual meeting of the German Pharmaceutical Association in Wiesbaden it was resolved to institute in connection with every district branch of that body an *Ehrenrath*, or council of honour, to which charges and disputes among its members, involving points of ethics, could be referred for decision, and a series of regulations as to the constitution and functions of these councils was drawn up and agreed to.

According to these rules each of these councils of honour will consist of five members, who, together with three deputies, are to be elected by means of voting papers from among the pharmacists belonging to the respective branches of the Association; the term of office is to be for five years, and each councillor must reside in the district over which the council he belongs to exercises its influence. It can be well understood that circumstances may arise which would render a seat in a council of honour very undesirable, and apparently in anticipation of such cases it is provided that acceptance of the office by a person who is elected is to be deemed obligatory, and an out-going member after serving a term may be elected to serve for another five years. Moreover resignation is to be dependent upon the consent of the other members of the council, who, however, may allow it if the reasons given are deemed sufficient. Each council is to elect its own President and Vice-President, whose duty it will be to convoke and preside over the meetings, the proceedings at which are to be considered private, whilst only such resolutions are to be deemed valid as are passed when five members of a council are present. The judgment of these councils of honour is to extend to all acts of members of the German Pharmaceutical Association which are alleged to be in contravention of its statutes, or injurious to the Association or an individual member of it, or to the community of pharmacists in general. As instances of such offences are specified: (1) injurious arrangements with medical men, such as for reciprocal recommendations, the supply of the specialties of a medical man, the composition of which is kept secret from other pharmacists, attempts to bribe medical men by presents, or partnership arrangements with medical men; (2) agreements with quack doctors and makers of secret remedies; (3) conduct towards customers which would tend to make them suspicious of other pharmacists; (4) neglect of obligations towards pupils; and (5) the giving of untrustworthy testimonials to assistants and pupils. Any member of the Association who wishes to have an inquiry set on foot concerning one of the above or other similar offences is at liberty to move a council of honour, but must put his charge in writing and show that it is well founded, the decision lying with the council whether an inquiry shall be instituted or not. Ordinarily the inquiry would take place before the council for the district to which the accused belongs; but the President of the Association will have the power, upon the application of the accused or of the local council, to order the case to be heard in another district. When, however, an inquiry is once commenced it can only be closed by a decision by the council on the question submitted to it, and will not be affected by the withdrawal of the accused person from the Association. Every council engaged in an investigation is to have the power to collect information and evidence, and to receive testimony orally or in writing, and every member of the Association is to be considered bound to answer truthfully all questions asked by a council. The accused, who may nominate another member of the Association to represent him, is to be entitled to receive, at least ten days before the time appointed for the hearing, an abstract of the motion, together with a statement of the grounds upon which it is based and the evidence that has been tendered in support of it. After consideration of the evidence, the decision of the council of honour may take the form of a rejection of the proposition, an open verdict, a requirement that a given scandal shall be removed, or a recommendation to the President of the Association that the offender be excluded according to the bye-laws. When a resolution has been arrived at it is to be communicated in writing to the President of the Association and to the person who has been accused, and the latter will have the right to appeal from it to the general meeting of the members.

From the foregoing summary it will be seen that the establishment of these councils of honour may mark a very important epoch in the history of pharmacy in Germany, and their proceedings, so far as they are revealed, will be watched with interest by pharmacists in other countries. The scheme was not without its opponents in the country where it is intended to come into operation, and in England, where so many influences tend to render pharmacists an undisciplined body, it will to many appear to be an extremely ambitious one. Certainly, there is a great probability that the decisions of the courts of honour will occasionally provoke considerable impatience and resentment, and if the law of libel in Germany at all resembles that of this country, considerable tact and discretion in the conduct of inquiries and the rendering of decisions will be required to ward off occasional unpleasant consequences. Of course very much will depend upon the support rendered by the members in general to those upon whom a decidedly unpleasant duty will devolve; but so far as we may judge from the fact that the proposition to institute these councils was supported by the votes of ninety-three out of a hundred and fifteen delegates from sixty-nine "circles," there is a widely-spread present desire to give them a fair trial. Success will not only be a boon to the pharmaceutical body in Germany, but it will prove the existence of an *esprit de corps* and homogeneity of sentiment among the pharmacists of the empire far exceeding that which is found in this country.

SIR WILLIAM SIEMENS.

At the commencement of the present week not a few readers of this Journal were looking forward to the rich intellectual treat of hearing an address from one of the greatest masters in applied science that the world has yet known, on the occasion of the opening evening meeting of the Society of Arts on Wednesday. But when that time arrived the lips which were to have spoken were for ever silent, Sir William Siemens having died suddenly and unexpectedly only forty-eight hours previously. Carl Wilhelm Siemens—or, as he preferred to be called after his naturalization in this country, William Siemens—was born in the kingdom of Hanover, in the year 1823, and his career is a bright illustration of the advantages of the sound system of education which has now obtained in Germany for many years and has contributed so much towards placing the people of that country in the front rank among the nations. Although perhaps the most gifted of an extraordinary family of brothers, it may be safely assumed that the powers of his mind were augmented by early scholastic discipline and that his brilliant inventive faculty was made many times more productive of good to mankind by the happy combination of scientific teaching and practical work which constituted his early education. Passing from the Gymnasium at Lubeck to the Polytechnic School at Magdeburg, and thence to the University at Gottingen, where he studied chemistry and physics under Wöhler and Himley, it seemed as if he only needed his subsequent experience in the famous engineering works of Count Stolberg to fit him, as far as education could, for the part he was to play in the world. It is curiously significant of the effect of this training that all the branches of it might be said to have been blended in his first contribution to applied science in this country, which was an improvement in electro-plating worked out by himself and his brother Werner. It is probably impossible, in consequence of the friendly reticence of the brothers, to define the exact share of the deceased in the labours which have made the name of Siemens a household word throughout the world, but there can be no doubt as to its variety, value, and far-reaching influence. The regenerative furnace, which made other good work in the manufacture of steel possible, and the inventions in connection with the practical utilization of electricity, are boons that will probably long continue to profit the human race. The versatility of the mind that could turn from the volatilization of metals in an electric furnace to the taming of the same fluid to the task of ripening strawberries, or from the construction of a thermometer that would register temperature at the bottom of the sea to settle the problem of the measurement of the temperature of the sun or to put forward and defend an ingenious speculation as to the maintenance of that source of heat, is productive of wonder in proportion as the nature and extent of the problems worked out by it are realized. It is no exaggeration to say that posterity will pronounce Sir WILLIAM SIEMENS *primus inter pares* amongst the band of foreigners who have repaid Old England for her hospitality by adding glory to her history.

Sir WILLIAM SIEMENS received many proofs of the high value set upon his labours, beyond that remuneration which follows success in business. He was twice elected President of the Society of Telegraph Engineers; he at different times held the same office in the Institution of Mechanical Engineers, the Iron and Steel Institute and the British Association; and at the time of his death he was Chairman of the Society of Arts. Only a few months since Her Majesty recognized his merits by conferring upon him the honour of knighthood. His death appears to have been due to an injury to the heart, the result of a fall in Hamilton Place whilst returning home from the Royal Institution about a fortnight ago.

It will be seen from the official announcement on another page that since the publication of the list of approved candidates for the election of annuitants from the Benevolent Fund, which takes place next month, information has been received of the death of Mrs. Rebecca Brand, whose name stood third on the list. We understand that the voting papers had already been printed, including, of course, Mrs. Brand's name; but, in order to prevent votes being wasted, the name will be marked through and the word "dead" stamped in the margin before they are issued.

* * *

One of the most interesting and instructive sights in connection with the recent meeting of the American Pharmaceutical Association at Washington is said to have been the large collection of materia medica in the National Museum, which appears to have been brought together under the auspices of the Government. It is reported to include specimens of nearly all the drugs in all the pharmacopœias of the civilized world, care having been taken that samples of average quality, suitable for educational purposes, shall predominate, rather than those that are unusually fine. When different kinds and grades are met with in the market, as in the case of gum arabic, opium or cinchona bark, all of them are shown as far as possible. Of more doubtful use is a series of pharmacopœial preparations. The organization of the Museum was the work of Dr. J. M. Flint, who received every assistance from Professor Baird, the Director of the Smithsonian Institution and National Museum. Many interesting specimens and much valuable information respecting them were obtained through the consuls of the Republic in foreign countries; but a large proportion of the official drugs appear to have been given by Messrs. Schieffelin. The question of the desirability of rendering this collection as complete as possible was brought before the members of the American Pharmaceutical Association by the President, and at his suggestion a resolution was passed to the effect that the National Museum should become the depository of the materia medica specimens belonging to the Association and all that may come into its possession.

According to a statement published in some of the French political papers the inspection of pharmacies in France during the current year has extended to 72,232 establishments, of which 9152 were in the department of the Seine, and the expense has been 296,474 francs. These numbers, however, would appear to be probably inclusive of visits to other places than pharmacies. An accompanying semi-official notice intimates that these inspections, as at present conducted, are considered to be both costly and useless, and that the Minister of Commerce is contemplating the substitution of the mixed commission of medical men and pharmacists, which at present performs the duty of inspecting pharmacies, by a single commissioner for each circumscription. The *Union Pharmaceutique* points to the fact that in the Bill of M. Naquet, which has received the endorsement of the Government, provision is made that the inspection in each department shall be conducted by a single inspector, who would be a pharmacist not in practice and residing in the department; but that this plan has been objected to, as not securing impartiality, by the executive of the General Association of Pharmacists, which has proposed that it should be amended so that each inspector whilst making his rounds in his department should be accompanied by the inspector of a neighbouring department.

* * *

The appeal of Liebig's Extract of Meat Company in their action against Mr. Anderson, in which the Company sought to restrain the use of the name "Baron Liebig's Extract of Meat," and also of a photograph of the late Baron Liebig with the words "Brand—Baron Liebig," has been dismissed with costs. The Lords Justices Cotton, Lindley and Fry were unanimous in dismissing the appeal without calling on the counsel of Mr. Anderson. It is to be hoped that an end to litigation has thus been reached, so that the trade in this useful article of food may in the future progress without embarrassment.

* * *

The "obituary" column in the *Times* of Monday last contained an announcement of the death, on the 14th inst., at Tunbridge Wells, of "Louisa Ann, widow of the late J. Pereira, Esq., M.D."

* * *

A list of Corrigenda to the United States Pharmacopœia, 1880, has been issued, and we understand that copies of it may be obtained on application to the publishers.

* * *

We have pleasure in stating that Mr. Samuel Goss, Pharmaceutical Chemist and Local Secretary to the Pharmaceutical Society, has been elected an Alderman in the Corporation of Barnstaple.

* * *

At the next meeting of the School of Pharmacy Students' Association, which will be held at 8 p.m. on Thursday, the 29th inst., Mr. T. S. Dymond will read some "Notes on Benzoic Acid," and a Report upon Practical Pharmacy will be made by Mr. R. A. Cripps.

* * *

The next meeting of the Chemists' Assistants' Association will be held on Wednesday evening, November 28, when a paper on "Essential Oils, their Derivation and some of their Uses" will be read by Mr. W. A. Wrenn.

Transactions of the Pharmaceutical Society.

NORTH BRITISH BRANCH.

EVENING MEETING.

The first meeting of the thirtieth session was held in the Society's Rooms, 119A, George Street, Edinburgh, on Wednesday evening, 14th inst., at half-past eight o'clock. Mr. John Nesbit, President of the Branch, in the chair.

After the transaction of some preliminary business, Mr. Nesbit proceeded to deliver the following—

Presidential Address.

Gentlemen,—It has pleased the Council of the Branch to place me in a position of grave responsibility, and one I had great hesitation in accepting, that of President for the ensuing session. I had the more hesitation in doing so on looking over the names of the many eminent men who have preceded me, men who will ever rank as the foremost of their day and generation in the annals of pharmacy. I am deeply sensible of my own inability to properly perform the duties appertaining to the office, and must rely on the assistance and indulgence of my fellow councillors, as well as of the other members and associates of the Society, and hope the session we are just commencing may be both a profitable and successful one.

I may congratulate the Branch on the recent change in the constitution of the Council, which has been as nearly as possible assimilated to that of the Society. It now consists of twenty-one members, fourteen of whom retire annually, but are eligible for re-election.

It is hoped that this increased representation will give a wider interest in the work of the Society and thus promote the best interests of pharmacy.

It appeared to me that we could not better spend a part of this evening than by discussing those interests which affect more or less every member of the Society, and to those I purpose directing your attention as briefly as possible.

We have it reported on undoubted authority that pharmacy on the other side of the Tweed is in a very depressed state; we may, however, congratulate ourselves, that it is, on the same authority, more prosperous in Scotland. It may not be out of place for us to consider the cause or causes that may lead to such a marked difference. Trade has certainly not suffered less here than in other parts of the country, and we may safely say that the incomes of every class, from the peer to the peasant, have suffered, in Scotland as well as in England, a considerable diminution during the last few years. If we have suffered less than other trades, and less than our brethren further south there must be some reason not far to seek for our greater prosperity. These reasons will be apparent in my further treatment of the subject.

Professor Attfield in a very able address recently delivered at Southport, at the opening of the Pharmaceutical Conference, shows very clearly the causes that have led to much of the depression. That address is a continuation of the one delivered at Southampton, in which the duties performed by the pharmacist to the State were discussed, while in the Southport address he shows distinctly the return which the State ought to make to the pharmacist for the proper performance of those duties. He shows that in many parts of the country, grocers, storekeepers and a host of other traders have commenced to deal in drugs. These men have no knowledge of the articles in which they are dealing, and, in consequence, the quality is very inferior, though, in many cases, more tempting to the eye of the inexperienced than the best quality, and the price is generally so low as to be merely a bait to catch customers for more profitable transactions. Others, again, who have no qualification, have opened shops in appearance chemists' shops, but they evade the law by not using any of the titles the qualified man alone is entitled to. This class professes not to sell any of the scheduled poisons, but it is generally understood they do not hesitate to do so when they can with safety to themselves. Medical men also have taken more to dispensing their own medicines than formerly, very possibly impelled by a decrease in their own professional incomes. It is not, therefore, surprising that those who have spent years in acquiring a knowledge of their business and have invested all their capital in it should suffer when subjected to such unfair competition. In consequence, almost every pharmacist has had his business much depreciated in value, and in some cases capital and means of livelihood have been entirely lost.

The remedy proposed, and with which I cordially agree, is to prohibit general dealers and other unqualified persons from dealing in drugs, with the exception of a few of the ordinary kinds and those used for domestic purposes. Such a remedy would be perfectly consistent with free trade. We do not ask a monopoly, but only that equal justice shall be measured to us as to other professions. We want no limit fixed to the number of those entering our profession. On the contrary we are ever ready to welcome every addition to the register. Every person must, however, have shown his qualification as a security that he is able to perform those duties to the public which ought only to be undertaken and can only be properly performed by a skilled pharmacist. Is it not, therefore, unjust to those who have at great outlay of time and money procured the qualification, to allow others, who do not even pretend to know anything of the goods in which they are dealing, to assume the same functions and undertake the same duties? The State imposes penalties on those assuming any of the titles of the pharmacist, and has thus admitted that those only who are qualified ought to deal in drugs. We may, therefore, fairly ask that unqualified men evading the law be subjected to the same penalties.

This affords us sufficient ground of appeal to the House of Commons to have the present Act amended so as to fulfil its original purpose.

We can easily adduce instances in which the State affords protection to class interests, and very justly so, as it is done in the interests of the public. We find that severe penalties are enforced against men who are unqualified assuming the functions of medical or legal practitioners. We have also in our merchant shipping service, which is the very embodiment of Free Trade, and which, in consequence, surpasses that of all the other nations of the world in extent and efficiency, just the kind of protection we want. Before a man is allowed to become the commander of a vessel, he must show to the Board of Trade that he has undergone a regular training and passed through the various grades of seamanship, and that he has a thorough acquaintance with the laws of navigation. No evasion is permitted. A man is not even allowed to navigate his own vessel unless he holds a certificate certifying that he is qualified. These precautions are taken to secure as far as possible the safety and the lives of the crew and passengers; not for the purpose of giving a monopoly to captains. We do not in consequence of these protective regulations hear that either medical men, or lawyers, or commanders of our vessels are in the least degree scarce or that they are able on account of this apparent monopoly to exact from the public large fees for their services. Neither would we be able to charge exorbitant prices for our drugs or for our services, as there is not and will never be in this country any limit to the number of men who may acquire the qualification and come in and share with us the grand "El Dorado" the public think we inhabit. Were we to seek to limit the number entering our profession, as in some continental countries, then we would be seeking a protection which will never be accorded to any class in this country.

In regard to the proposal to supply medicines in sealed packages to village shopkeepers, that seems to me unnecessary. There are advantages and disadvantages in a country life, and not the least of the latter is the inconvenience of having sometimes to send several miles for a medical man; alongside of that must be placed the inconvenience of a chemist being also at a distance. My experience of the country, which is not inconsiderable, is that the poorest of families provide themselves with a supply of such medicines as they can safely use in case of illness, a practice which might be followed by dwellers in cities to the great advantage of themselves and the slumbers of their chemist.

Prior to the passing of the Pharmacy Act, 1868, it was not uncommon to see in little village grocery shops tincture of rhubarb and laudanum standing side by side; but since the Act came into operation the laudanum bottle has disappeared, and, so far as I know, without any inconvenience to the public. On the contrary, its disappearance is rather an advantage. Its sale in many cases only encouraged the habit of laudanum drinking, it being sold to all comers, and no questions asked. If a few more articles were similarly prohibited I do not think our country friends would be seriously inconvenienced. At all events, the advantage of getting drugs of the best quality and always in a fresh state from the nearest pharmacist by means of the parcels post would more than counterbalance any inconvenience that might be experienced in the loss of the present source of supply.

Having discussed the salient points in Professor Attfield's address, we will now endeavour to discover the difference between pharmacy here and on the other side of the Tweed. In London and the large towns in England we find establishments which are model pharmacies, in which our profession occupies the place our Society has always aimed at obtaining for it. These exist by the dispensing of prescriptions which, is really the "Be all and end all" of pharmacy. Another and a larger class exists where few or almost no prescriptions are dispensed. These exist by supplying such drugs as are required by the public in domestic practice and the sundries kept more or less in all pharmacies, and not infrequently by trespassing on the province of the medical man. On the other hand medical men largely invade our special province, not only by dispensing for their own patients, but frequently by keeping open shop, for which latter they are only in rare instances qualified. We gladly admit their qualification for their own special department, the practice of medicine, but it is well known that they have little or no training to enable them to practise pharmacy.

In Scotland the case is somewhat different, unless in some places on the west coast. In Edinburgh and most other large towns medical men do no dispensing. Even in country districts they prefer to be relieved of work of that kind. Consequently we frequently find in country villages pharmacists who derive their incomes chiefly from dispensing the prescriptions of the practitioners in the neighbourhood. Many such small establishments exist throughout the country, where more prescriptions are dispensed in one day than in a month in much larger establishments in England. This alone would account for much of the prosperity attributed to us.

We, however, have some recognition by the Government, which so far as I know is altogether wanting on the other side of the border. As a rule our parish doctors are only paid a yearly salary for attendance on paupers, in which medicines are not included, as they are supplied by the local chemist and paid for monthly by the Parochial Board at moderate dispensing prices. The Board of Supervision representing the Government insists on this arrangement as far as possible, and it is perfectly entitled to do so, as whatever amount is paid in the shape of medical relief by the parish is half refunded by the Government. So far as I know such an arrangement has never been attempted on the other side of the Tweed. The parish doctors there universally supply medicines, which on medical authority are usually of the commonest and cheapest kinds. It is unfair to the pauper that this system should exist. The medical man considers the salary he receives as a fee for his professional services, and the medicine he supplies simply as a deduction from it; hence the poor pauper suffers. No doubt such dispensing in the aggregate would not be of much value in a money point of view to the chemists throughout the country, but it would have a considerable effect in doing away with medical dispensing; when it was seen that paupers required both a doctor and chemist, the classes above would be quietly educated to get for themselves the same advantage.

Moreover, we do not find that our large hospitals give medicines to all comers as in England. Our Edinburgh Infirmary, which may be considered the foremost in Scotland, has in the course of the year some sixteen thousand out-door patients, who are prescribed for by the physicians in attendance, but are required to procure their medicines from their own chemists and at their own expense. The same system is pursued in other towns in Scotland, and may be recommended to the governors of similar institutions in London, as a direct means of lessening the occasion for those urgent appeals for money so often to be seen in the *Times* and other newspapers. It would also help in promoting that thorough and manly independence of character so characteristic of all classes in Scotland, and not less so of the working man than of any other.

Wherever pharmaceutical work is to be done it should certainly be committed to a qualified man. Our successive Governments have only, however, recognized this in the army and navy on rare occasions. There is necessarily with such large bodies of men a large amount of dispensing done, as well as large quantities of medicines consumed. The dispensing is supposed to be performed by the medical men of the various regiments, but it is really done by the common soldiers, who can have no knowledge of the nature of the drugs and preparations they deal with. To get men to perform duties they have no knowledge of and no special qualification for may have the appearance of economy, by saving the salary of a qualified dispenser, but it is not really in accordance with the teachings of our political economists. How far such a proceeding may be a disadvantage in times of peace, how far it may affect the health or even the lives of our soldiers we have no statistics to show; but in times of war the disadvantage of there being no permanent staff of pharmacists is frequently too apparent, not only in the want of a proper supply of drugs, but also in the want of dispensers. Those of us who are old enough to remember the Crimean war know with what hot haste dispensers were selected and despatched to the seat of war,—not, however, till the army had suffered considerably from the want of them. Medical stores, which it would have been the duty of the director of a pharmacy staff to provide, were in many cases sadly deficient. Opium was frequently not to be had, while men were dying of diarrhœa and dysentery. Lime water was, however, as I have been informed, to be had in great abundance, it having been sent from London carefully secured in pint bottles. Such management is the reverse of economical, to say nothing of the dictates of humanity.

Various proposals have been made for the regulation of the patent medicine trade. There can be no dispute that the Pharmacy Act ought to make no exception in regard to those containing poisons. A Government stamp does not make a poisonous preparation harmless, and certainly does not convey to the public any idea that caution is necessary in the use of such preparations. It has been suggested that the stamp should be discontinued, as it is accepted by the public as a guarantee not only of the quality, but of the wonderful virtues of the preparation it covers. I altogether disagree with such a proposal. We find our Government derives a large revenue, and rightly so, from taxes on wines and spirits and also tobacco. Now I would place patent medicines in the same category, and instead of discontinuing the stamp would at least double its price, and instead of printing over it the name of the manufacturer, would put the following or something to the same effect: "This stamp is no guarantee of the quality or virtues of the medicine." Many of these preparations contain very poisonous drugs, and I would insist on the names of all poisonous ingredients being distinctly stated on the label, instead of the too common practice of labelling them with the name of some simple and harmless domestic remedy,—such as aniseed, horehound, linseed, etc.,—which is very misleading. How far it may be justifiable to allow such compounds to be sold at all is questionable. We know that very serious results frequently ensue from their habitual administration to young children. Much of the infantile mortality of our large towns doubtless arises from this cause, and much also of the weakness of intellect becoming more and common in our adult population. I would, therefore, suggest that the formula of all such preparations be registered,—their composition and freedom from danger to the public reported on by a joint committee of medical men and pharmacists before a licence be obtained by the manufacturer for their sale.

Every member of our Society must have seen with satisfaction the action taken by the Pharmaceutical Council in asserting our rights to assist in the framing of a new Pharmacopœia. Had the Bill of the Medical Council become law we have every reason to believe that our claims would have been admitted by the Legislature. If a Pharmacopœia were only, as has been asserted, a doctor's prescription book, then we could have no claim to be represented on the Committee. It is to my mind quite different from a mere hospital formulary or those handsome compilations so freely circulated by our friends from the other side of the Atlantic. It is a statutory work for the use and benefit of the public, and not for any particular section of it. It ought to contain a list of the drugs and chemicals in ordinary use, to describe the physical and chemical properties, and give tests for indicating their purity and strength. It ought to contain formulæ and instructions for making such galenicals as are always in demand. These ought to be of a simple nature, representing the various drugs and chemicals in the most convenient and efficient form for administration or ready combination by the instructions of physicians.

If this view be a correct one, then it must be admitted that medical men as such are entitled to no more than a share of the work of framing it.

The Medical Bill will no doubt be reproduced during the next session of Parliament. It will therefore be necessary for us to take the same steps as we did in the last session to have our rights recognized.

Should our efforts be crowned with success then I would suggest that a permanent committee be appointed for the purpose of revising or making additions as occasion may require. All would reap the advantage of such an arrangement, none more than ourselves, as our doubts in regard to the strength of new preparations always being introduced would be considerably lessened by the publishing of recognized formulæ. Another advantage would be the bringing of the Pharmaceutical Council into closer contact and more intimate relationship to the Medical Council.

We are a branch of the medical profession, but a branch almost separated from the trunk. Anything, therefore, that would create a better understanding between the two bodies would be for the advantage not only of ourselves but also of the public. Such a body would also be able to advise the Government in regard to the licence to be granted to manufacturers of patent medicines containing poisonous ingredients. The pharmaceutical portion of the committee could report on their composition,—the medical on their safety and usefulness to the public.

I will now only allude to pharmaceutical legislation. An impression seems to prevail even in our own ranks that we have always initiated legislation. Such a view is quite erroneous.

The first formation of our Society, in 1841, was due to an attempt made by the College of Physicians to legislate for us. Prior to that time no combination existed among chemists, each man followed his own course independently of his neighbour. In that year, however, the famous Hawes's Bill was introduced, which proposed, among other medical reforms to license an entirely new class of pharmacists, who would gradually have superseded those in business, many of whom were men not only eminent in their own calling, but also in their scientific attainments and social position. Such men were not likely to sit idly by while a Bill was being discussed in Parliament which would, if it had become law, replace them by men who might have no knowledge of pharmacy, but had only received the imprimatur of the College of Physicians. Such an attempt at spoliation led to a combination of the trade. Petitions were sent to both Houses of Parliament from all parts of the country, with the result that the Bill was withdrawn. That combination continues to the present day, for shortly after it formed itself into the Pharmaceutical Society, receiving a Royal Charter, and in 1852 an Act of Parliament confirming its rights, but giving it no privileges. Again, the 1868 Act was the result of pressure springing out of a communication from the Medical Council to the Government suggesting that some enactment was required to ensure competency in those practising pharmacy. We were, therefore, again compelled either to legislate or be legislated for. A Bill was consequently promoted by our Society, and another by the Society of Chemists and Druggists. We have it on the highest authority that a house divided against itself cannot stand and we find that neither of the Bills became law, but instead we received a Poison Bill, a compromise between the two parties which may have been of service to the public, but certainly of doubtful advantage to us. It is, however, unfair to attach blame to our Society for the result, as that time it only represented a small portion of the trade. Had the various sections of it gone forward as a united body, on the lines of the Bill of the Pharmaceutical Society, no doubt the result would have been different, and it is questionable whether the Act would have required amending at this early date.

We are again attempting legislation, not, however, at the call of the Medical Council, but this time in response to the demands of the public expressed through the Government to have poisons placed under still greater restrictions. The Draft Bill, if it were to become law, would not give us all we are entitled to but would place us in a much better position than we are in at present. The chief of its advantages would be that the dispensing of prescriptions would be left entirely in our hands. In it we do not claim the exclusive right to deal in some of the poisonous chemicals largely used in the arts and manufactures, but we claim the right for the protection of the public to see that those dealing in them label them "poisonous." A deal of opposition has been offered to this clause which seems to me groundless. Such chemicals are not used in medicine only, and therefore as pharmacists we have no right to a monopoly in their distribution. Few pharmacists would, I venture to think, care to leave their dispensing counters to supply a gallon of spirit of salt or oil of vitriol; besides, we have not the exclusive right to their sale at present, and to ask for such would wreck the prospects of our Bill.

The apprenticeship clause will be of great service by preventing disappointment to young men entering the business, and will permit of them applying themselves to the acquirement of a knowledge of their profession instead of studying what ought to have been learnt at school.

Legislation is at best a slow and uncertain process.

The Council of our Society have in consequence taken steps to enforce a curriculum. It may seem a hardship to young men to be compelled to pass six months at a School of Pharmacy after having served an apprenticeship. Yet we find that there are few young men in Scotland who do not endeavour to fit themselves for their responsible duties by attending courses of lectures in a university town.

The adoption of the scheme will ensure for the chemists of the future a better social position and more pharmaceutical work. We must ever bear in mind that the watchword of our Society has been "Education and Qualification." I would only, in conclusion, suggest the addition, "Union," and urge on you all to use your influence to bring within the pale of the Society those who are now without. For if we appeal to the Legislature as one man, there can be no doubt that we shall be successful in obtaining our legitimate demands.

Mr. J. B. Stephenson, in moving a vote of thanks to the President, said that he felt that those present would join with him in appreciation of the address. He considered it fortunate that it was not usual, nor did he think it proper, to criticize a presidential address, for in this case so many points had been touched on that one could scarcely attempt to criticize them all. He felt that he could give general support to the views expressed. He thought that Mr. Nesbit had done wisely in drawing attention to the difference, or causes of difference, between English and Scotch pharmacy; that was a matter worth looking into. Referring to pharmaceutical legislation he said that the Pharmacy Acts Amendment Bill would meet many of the hardships complained of by pharmacists, and everyone connected with the profession should, therefore, back up the efforts of the Society to get not only that Bill enacted, but to aid in obtaining the demand which they had made when the Medical Bill was brought into Parliament last session, and he could not imagine that their demand would be refused, considering the approval which the proposed Pharmacopœia Clause had received from members of Parliament and medical practitioners.

Mr. J. R. Young seconded the vote of thanks and agreed with the remarks which had fallen from Mr. Stephenson regarding the address. The point which had particularly struck him was that regarding the privilege which Soctch pharmacists have in dispensing medicines for parochial boards. Apart altogether from any consideration of the business advantages or disadvantages of this system, he felt that it embodied a sound principle, namely the recognition of the province of the pharmacist. He hoped that steps would be be taken to have the similar rights of English pharmacists clearly laid before the proper authorities; if the right were conceded parochial medical practitioners would be relieved of work which can only be irksome to them; it would be beneficial to the paupers, and parochial funds would not suffer, since Government meets a share of the expense. He thought that this was a most important matter, and one which should not be overlooked.

Mr. J. L. Ewing supported the motion and asked indulgence for what might appear to be a criticism of the address. He could not help expressing the opinion that the patent medicine stamp should be abolished, for to a certain class of the public it conveyed an impression or guarantee of the value of medicines which came under the tax. The revenue would suffer but little were the tax repealed, for he had gathered from Mr. Hibbert that the amount is so paltry, that its loss could not be considered an obstacle to the reform. Another matter which he would like to refer to was the increase in the number of pharmacies in Scotland, and taking Edinburgh as an example he thought that the number was quite out of proportion to the population. His position as convener of the local price committee had given him some acquaintance with the increase in Edinburgh during the past seven years, and he found that there were at least thirty-seven new shops opened in Edinburgh and Leith during that period. The number had thus so far outrun the proportion of the population, that they had one pharmacy for every eight hundred inhabitants. If this state of affairs continued he felt that the life of the pharmacist would indeed be one of labour and toil, but not of remuneration.

The motion having been heartily responded to by the meeting, Mr. Nesbit returned thanks and called upon the Secretary of the Branch to read his report of the donations received during the recess. These donations comprise the following:—

To the Library:—

'Proceedings of the Vermont Pharmaceutical Association,' 1882. *Two copies.*

'Proceedings of the American Pharmaceutical Association,' 1882.

'Report of the Smithsonian Institution,' 1881.

'Annual Report of the Philadelphia Alumni Association,' 1882.

From the Respective Publishing Committees.

Richter's 'Typo-nucleus Theory.'

From Mr. Peter Boa.

To the Museum:—

Large cube of barbaloin, specimens of strychnia arseniate, nitrate and sulphate and pure alkaloid.

From Messrs. T. and H. Smith and Co., Edinburgh.

Specimen of oil of sweet birch (*Betula lenta*) and salicylic acid prepared from the same.

From Mr. Kinninmont, F.C.S., Glasgow.

Specimens of yellow prussiate of potash,

From Mr. Alexr. Napier, Edinburgh.

Specimens of pure aldehyde, cannabinum tannicum (Merck), cotoin, paracotoin, hippurate of soda and beta-naphthol.

From Messrs. Clark and Pinkerton, Edinburgh.

Herbarium specimens of indigenous medicinal plants.

From the Curator, Royal Botanic Gardens, Edinburgh.

Specimens of *Camellia oleifera* products, illustrative of a paper published in this Journal, July 14, 1883. From Mr. Hugh McCallum, Hong-Kong.

Mr. Gilmour moved a cordial vote of thanks of the donors.

The following paper by Mr. George Burrell, Montrose, was then read by Mr. MacEwan, in the unavoidable absence of the author:—

A Few Hints to Young Pharmacists.

Advice is somewhat like the articles the pharmacist is familiar with, more pleasant to give than to take, and yet like those articles it has its peculiar province and usefulness. Those who are encased in a robe of self-complacency may think it as superfluous as a tonic would be to one whose appetite and digestion are sound and vigorous; but to the modest, anxious, inquiring young man, who has a healthy desire to better himself in person and in circumstances, and whose conceit has been nipped in the bud by coming in contact with high models, the utterances of experience are not without value.

That class do not listen to the opinions of older men with a self-satisfied smirk, nor show any desire to sneer at those who may not be familiar with modern scientific terminology, the mere scaffolding of knowledge, but having found that flabby cram will not impart robustness to the understanding, and that the mind needs something more substantial than complicated formulæ to live upon, they gladly receive whatever may minister to their intellectual growth. To such I venture to address the following remarks.

It is, some would say, a mere truism to affirm that work is our appointed task, that we must live by the sweat of our brow; and yet the very familiarity of this maxim is apt to make us overlook its deep significance. Healthful and sunshiny labour can be easily and pleasantly portrayed in a glow of poetic beauty, especially by one sitting in an easy chair, with a comfortable dinner in the prospect, and everything cosy about him; but to the man who has so many cubic yards of broken stones to accomplish to meet his weekly needs, and who is pretty familiar with home cares and short commons, it presents a different aspect. At the same time, in spite of all sentimentalizing and grumbling, it is an established fact, that the stone-breaker, and every man, is happier when working, than when idle.

Hear what the most powerful thinker of modern times, says on the subject:—

"A man perfects himself by working. . . . Even in the meanest sorts of labour the whole soul of a man is composed into a kind of real harmony the instant he sets himself to work! Doubt, desire, sorrow, remorse, indignation, despair itself, all these like hell-dogs lie beleaguering the soul of the poor day-worker, as of every man; but he bends himself with true valour against his task, and all these are stilled, all these shrink murmuring far off into their caves. The man is now a man."

This is the key-note of much of Carlyle's healthiest teaching.

Let us now consider what the work of the young pharmacist is.

Having attained to the dignity of Minorhood, the door of exclusion is opened and the great highway of life which he has to traverse lies before him. He cannot now make a bicycle of his text books and compendiums, and patent contrivances for quick and easy intellectual locomotion; his mind has emerged from the feeding bottle process, and like a child who instinctively kicks and sprawls until he gets rid of the fat which clogs his tiny muscles, our young pharmacist casts off all mental coddling, and steps out on his own legs.

In very truth his real education now commences, which will end only with his life.

In due time he meets with the inevitable obstacles—disappointments, slow progress, small drawings, bad debts, rash purchases, long hours, occasional sleepless nights, dyspeptic twinges, unreasonable customers whom he is obliged to humour, capricious patrons inclined to lord it over him a little, unruly apprentices, unreadable prescriptions, cutting prices, measures and funnels going to smash, jealous and sometimes not over scrupulous *confrères*, and so on.

By the time he has encountered most or all of those difficulties, he has found that the teaching of George Street and Bloomsbury Square has to be supplemented by a sterner and deeper philosophy.

His Majesty the Public, whose servant he has become, however appreciative of honest endeavour, is at the same time somewhat exacting, and is apt to forget that the pharmacist has a digestive apparatus and a soul like other men; hence untimely calls at meal and sleeping hours and frequent interruptions of religious duties.

I have advisedly presented my subject, at this stage, in a sombre point of view, to serve as a back-ground to the brighter tints which I can legitimately throw in. Although the training of the pharmacist is not intended to fit him for the highest walks of scientific research, he yet has abundant scope in his particular department to develop and exercise every faculty. If he cannot penetrate to the inner sanctuary of the Temple of Science, he may get a glimpse of it from the outer courts. Every article he deals in invites his careful study, and every preparation of the Pharmacopœia may suggest a fruitful train of interesting speculation; every vegetable within whose tissues medicinal virtue lurks, and every chemical which helps to assuage pain or prolong life, are subject to his skill. Moreover, the exercise of his duties calls into activity a happy combination of intellectual acumen and manipulative dexterity. I do not envy the man who depends entirely on "the quick forge and working-house of thought," for if his career be brilliant, his life is too frequently short. Pure brain-work of the highest class may secure enviable prizes, but it is generally accompanied by much physical torment. A great deal of Carlyle's comfort depended upon his potatoes or oatmeal being properly boiled, and there is no doubt the gloom which overspread so many of his reflections had its origin in the life-long dyspepsia which almost maddened him.

If you want to think out a subject keep your fingers employed in some little job not needing much care, such as cutting labels (not round ones though); and when tired with thinking take the pestle, or spatula or test tube and do a little work. Manual occupation seems to assist the action of the mind somewhat in the same way as an instrumental accompaniment does the voice in singing; and it might be an interesting subject of investigation to determine how far the delightful conversational powers of our dear lady friends depend on the ceaseless activity of their fingers. When you have any leisure in the shop, make it a rule to read nothing but professional books *there*—except, of course, on Sunday, which should have its appropriate studies. We have an old, large and interesting pharmaceutical literature, in addition to the current and old numbers of the *Pharmaceutical Journal*, the *Chemist and Druggist*, the 'Year-Book of the British Conference,' and kindred publications, which afford plenty of healthy reading to keep you abreast of the day and to give you hints of great practical value.

Acquire the useful habit of noting any thought suggested by your work or reading, for I believe many fruitful ideas are lost by not being registered at their birth. The 'Chemist and Druggist's Diary' is very handy for that purpose. While doing everything in your power to perfect your skill as a pharmacist, do not forget you have the character of an intelligent man to sustain, and for that purpose you have the grandest literature in Europe to help you. Intercourse with the "mighty dead" is the solace of life, and no one need weary when he can at will commune with Shakespeare, Milton, Bacon, and the long and brilliant array of authors who have succeeded them, and whose works are accessible to all.

As our calling requires not only a considerable amount of scientific knowledge, but also an intimate acquaintance with mercantile principles, it is sometimes difficult to make these two elements co-operate advantageously. Our charges do not, like the fees of medical and legal practitioners, rise with our reputation, but are regulated by the "prices current," and by the kind and amount of competition we encounter.

It is this mixture of the merchant with the scientist that gives rise to the most difficult questions we have to determine. If we were adequately remunerated for the amount of skill and care we are obliged to exercise, we might dispense with many articles which anyone can buy and sell; but under present circumstances we are debarred from that and obliged to defend ourselves from the incursions of outsiders by overlapping, to a certain extent, their territory.

It is certainly unjust, that one man should be obliged to go through an expensive course of scientific training to secure a legal qualification to sell poisons, while another with little more than the knowledge of the three R.'s, and no compulsory qualification, should be allowed to sell both *unscheduled* poisons, and compounds containing articles included in the *scheduled* list!

This raises the vexed patent medicine question in which so many are vitally interested. Shall we, by giving up a *part* of the profit, keep that branch of our trade, representing a turn-over of probably a million and quarter sterling or more; or by sticking to the full prices surrender the whole or most of it to outsiders? Shall we allow grocers and others to tempt our customers to buy articles on which they have a large profit, by supplying them with patents, etc., at a little above cost price?

We can sell quack medicines without being quacks—can we *make* as well as sell them, without endangering our pharmaceutical integrity? In short, to many, the real question may be—shall we *live* by unbending to a certain extent our scientific dignity, or shall we *die* in the odour of pharmaceutical sanctity?

My own opinion is, the most dignified, most legitimate and wisest course to follow, would be to agitate for the abolition of the patent medicine stamp. This tax is not only a paltry one for a great country to exact, but it is also an *immoral* one, inasmuch as Government places its imprimatur on the basest as well as on the most unobjectionable compounds. By its removal, secret medicines would stand on their own merits, and the pharmacist would have a fair field for his skill and ingenuity; while the public would be relieved of an unjust imposition and be supplied with safe and efficacious remedies, for half the price they pay for so many which are worthless and mischievous. I am sure that policy would secure the powerful aid of our medical friends, and save us the experience of the *reverse* of Pharaoh's dream—the sleek and well-fed grocer gobbling up the traditionally lean apothecary!

Great and laudable efforts have been made to raise our status, by giving a more scientific complexion to our calling and securing thereby a more efficient discharge of our duties and a consequent increase of confidence on the part of the public; and it is left to the young pharmacist to carry on and perfect what his predecessors have so well and laboriously inaugurated. The memory of the late Jacob Bell and the other public-spirited founders of the Pharmaceutical Society, will be held in enduring and grateful remembrance by those who have benefited so largely by their labours. The examinations which our young men have to go through, may appear to them too much like a hurdle-race where there are as many stumbles as successful leaps; but by and by, they will regard these trials of their mettle with the same feelings an old man thinks of the cricket matches of his youth.

I would recommend every young pharmacist to join the Pharmaceutical Society. Many complaints have been made of the little the Society has done, and the much it has left undone; as if an association comprising so small a proportion of chemists and druggists could do what the combined strength of the whole body might find it difficult to do. A large membership would encourage the Council to show a bold front when circumstances required it; while it would more truly represent the general opinions, and more powerfully foster the common interests. Many become members without any prospect of personal benefit; but they have the satisfaction of being connected with an association recognized and respected by all whose opinion is of any value. The man whose mind is cooped up in his own mortar will have no more influence than its pestle. In the meantime we are too much like a crumbly pill-mass, in need of something adhesive to make us *roll.* Hearty and intelligent co-operation is that something, and so long as that is wanting, we may show some kind of *motion*, but there can be *no go.* The young pharmacist must work incessantly, to perfect himself in his profession, and his constant endeavour should be, either to improve an old preparation, or to devise a new one. That will prove an effectual protection against the assaults of outsiders, and he will find that in raising his *own* status he will most efficiently help to elevate the character of the whole body. It will never do to rely entirely on legislative interference, which at best is but a compromise between conflicting interests; what we want is *justice* not *protection.* A legal qualification implies an *illegal dis*-qualification, and it is but common justice that those who have the former should not suffer from the encroachments of the latter class, especially when the public welfare is so largely affected by the distinction. The crisis through which our trade is at present passing, clearly indicates the necessity of a large and powerful combination, without which, I fear, a vast number must submit to absolute extinction. At the same time it must be remembered, we are suffering, like other commercial interests, from the present general depression, which we have reason to think is passing away.

The time also may come, when the quack successors of Pontius Pilate who are bawling out "What is Truth?" and answering the question by pitching a thirteen pence halfpenny box of their pills into the stomach of the doubter, will give place to the unpretentious pharmacist, who will do his honest work, without fuss and brag.

Mr. Young said he had great pleasure in moving a vote of thanks to Mr. Burrell, whom he had known for forty years as a pharmacist who took considerable interest in the affairs of his profession; in fact, he seemed to be a Nestor in pharmacy. He felt that the young men could, with every confidence, receive Mr. Burrell's advice, which was given in a style of his own, rugged no doubt, but sage and trustworthy and very entertaining.

Mr. Baildon seconded the motion.

Mr. Hill expressed the pleasure which he had had in listening to the paper, and he felt that he could speak for other young men in saying that the advice was so given that it would not be received with a smirk, but with that consideration which was due to a man of Mr. Burrell's wide experience in pharmacy. At the present time, he remarked, a crisis in pharmacy has been reached and that cohesion which has been referred to was now more desirable than at any other time. He was not one who took the pessimist view of the situation—that pharmacy is "going to the dogs." This cry proceeded mainly from those who were outside of the Pharmaceutical Society, those who held that it is only the mercantile and not the scientific part of pharmacy which requires cultivation. This he believed to be a mistake, for scientific principles were the basis of the profession, and it was only the scientific part which would carry the other through the crisis. He could scarcely agree with Mr. Burrell's remark that the pharmacist could not hope to enter the inner courts of the Temple of Science, for many of the most eminent chemists had begun their studies, and often made their greatest discoveries, while they were connected with pharmacy. Scheele and Liebig were of this class. He felt that the younger members would appreciate Mr. Burrell's hints.

Messrs. Boa and Henry endorsed the remarks of the other speakers, and the President of the Branch said that it would give him great pleasure to convey to Mr. Burrell the vote of thanks which had been accorded to him.

The meeting then adjourned.

Pharmaceutical Society of Ireland.

MEETING OF THE COUNCIL.

The monthly meeting of the Council was held on Tuesday, November 7, at 11, Harcourt Street, Dublin, the President, Mr. Brunker in the chair.

Present:—Messrs. Harry Napier Draper, J.P., F.C.S., Vice-President, William N. Allen, Henry Bennett, Thomas Collins, M.R.C.S.E., William Hayes, John Evans, L.A.H., George H. Grindley, Edward M. Hodgson (Treasurer), Robert Montgomery, L.A.H., M.R.C.S.E., Robert Simpson, William F. Wells, jun.

The minutes of the annual meeting of the Society and of the last monthly meeting of the Council were read and confirmed.

Letters were read from Mr. Robert T. Herron, L.P.S.I., Armagh, and from Mr. James Williamson, solicitor, relative to the recent prosecution of two persons named Gray for selling drugs without possessing the necessary qualification. The defendants had been convicted and fined £2 in each case with £1 costs—in all £6. The letters requested the Society to forego their claim to a portion of the penalty, and to allow the entire to be retained by Mr. Herron to defray the expenses attendant on the prosecution, which it was stated would amount to the entire sum recovered.

The President said the Society had permitted Mr. Herron to institute the prosecution in their name, on the understanding that they should be at no expense in the matter. Mr. Herron now, however, wanted them to go further, and to concede to him the portion of the fine to which they were entitled by statute. It was for the Council to consider whether they would concede that application.

Mr. Hodgson said the Society was entitled under the 36th section of the Pharmacy Act to two thirds of the fine, and Mr. Herron to the remaining third. The Society had consented to allow Mr. Herron to institute this prosecution in their name at his urgent request, in order to put down the illegal vending of drugs which he complained of as being carried on by unqualified persons in his neighbourhood. It was a very proper proceeding, and the offenders had been fined; but it was very doubtful whether the Council had any right to forego the statutory right conferred on the Society to two thirds of the penalty.

Mr. Allen: Is there any direction in the Act of Parliament as to how the fines shall be disposed of?

Mr. Hodgson: The Act says that one third is to be paid to the person who shall be the means of bringing the offenders to justice, and that the remainder shall be paid to the Treasurer of the Society to be by him applied in carrying out the purposes of the Act.

Mr. Wells apprehended the section had application only to cases in which the Society were themselves prosecuting.

Mr. Hodgson said that was a mistake. The statute did not appear to contemplate that the Society should be prosecutors at all. The police were to prosecute for infringements of the Act, but two thirds of the fine should go to the Society and the remaining third to the person who was the means of bringing the offenders to justice. He apprehended the proper course would be that the two thirds of the fine should be handed over to the Council, and they then could consider whether any portion of it should be given to Mr. Herron to defray the expenses of the prosecution.

Dr. Collins said it was the duty of the Council to encourage members of the Society—especially members in the country—in prosecuting persons guilty of infringing the Act; and he thought it would be treating Mr. Herron harshly if the Council insisted on retaining the money and left him to defray the expenses out of his own pocket.

The President apprehended that in the absence of any bye-laws dealing with the subject the Council had no choice but to require two thirds of the fine to be remitted to their Treasurer in pursuance of the Act of Parliament. At the same time he was of opinion there was a good deal in what had fallen from Dr. Collins, that it would be a great pity to throw cold water on the efforts made by country members to put down the dispensing by unqualified persons. Such efforts ought to be encouraged.

Mr. Hodgson disclaimed any intention of throwing cold water on the efforts made to prosecute infringements of the Act. He merely wished that the Council should keep within their duty as defined by the statute.

Dr. Montgomery said under the circumstances of the present case he would be inclined to allow Mr. Herron to retain the entire fine, as it appeared he had been at such expenses in the prosecution; but he thought the Council should be cautious how they acted in the matter, lest it might be supposed they were making a precedent for future cases.

Mr. Draper said the proper course would be for the Council to require in the first instance the entire two-thirds of the fine to be remitted to the Treasurer, and, subsequently, Mr. Herron's application for a portion of the money might be taken into consideration. The Council were most anxious to encourage their members and to assist them in every way in putting down the illegal dispensing by unqualified persons. Such assistance was one of the strongest inducements which could be afforded to licentiates to support the Society.

Professor Tichborne said the amount of the penalty fixed by the statute, section 30, for infringing the Act was £5, and he did not understand why in the present and other cases it had been reduced by the magistrates to £2. According to his reading of the Act the magistrates had no power to reduce the penalty.

The President believed the magistrates sitting in petty sessions had the power of mitigating fines in all cases unless expressly precluded from doing so by statute.

Mr. Allen proposed and Mr. Draper seconded the following resolution, which was agreed to:—

> "That Mr. Robert T. Herron be informed in reply to his letter of October 11, that the Council cannot entertain his application, they having no alternative under the 36th section of the Act. The Council will, however, take into consideration Mr. Herron's application for a grant towards expenses incurred by him."

A communication was read from Mr. John P. Short, L.P.S.I., of Kells, relative to establishments carried on by unqualified persons.

The President said the letter did not mention the names of any of the parties referred to, and he apprehended the proper course would be to ask Mr. Short to report the circumstances of any cases which had come under his notice, for the information of the law committee. The Registrar was directed to communicate with him to that effect.

A letter was read from Mr. P. J. Finnegan thanking the Council for acceding to his request as reported in the proceedings of last monthly meeting.

A report of the Law Committee was received and adopted and a series of queries relative to the interpretation of the term "person keeping open shop" were ordered to be laid before the Solicitor-General for Ireland.

Mr. Hodgson (Treasurer), pursuant to notice, moved—

> "That the original members of the Society be *requested* to pay the same annual subscription as the elected members of the Society."

He apprehended the notice might require some slight alteration in its wording as there was no doubt the Council could not require the original members to contribute to the funds of the Society, they having been constituted members by Act of Parliament, and it being beyond the province of the Council to require any contribution from them unless they were willing to give it. What he wished was that the members in question should be applied to, and asked to contribute to the funds of the Society, as from its financial position it was desirable that as much support should be obtained for it as possible. He (Mr. Hodgson) as one of the original members was quite willing as far as he was personally concerned to pay the same contribution as the elected members. The Society required larger funds than they had at their command, in fact an inspection of their balance sheet would show the absolute necessity of doing something to increase their income.

The President thought the resolution might very well be adopted in the terms drawn by Mr. Hodgson in the notice of motion. The notice merely proposed that the members be "requested" to pay the subscription; he thought it was quite within the province of the Council to make such a request. It would of course be optional with the members to comply with the request or not as they deemed proper.

Professor Tichborne said the question was whether the resolution should apply to those members who did not take an active part in the Society. There were only five of the original members on the Council now.

Mr. Hodgson said that was so; some of the original members had passed away, but some were still living who were not members of the Council.

Mr. Draper agreed with the Treasurer that it was most important for the Council to endeavour to increase the income of the Society and although he was not very hopeful of the motion being carried out to any considerable extent, he so entirely sympathized with the object in view that he would second it.

The motion was then agreed to.

Professor Tichborne, pursuant to notice, moved—

"That a Committee be appointed to report to the Council on the future supply of the Journal to members of the Society and as regards the reporting of the proceedings of Council."

The matter did not require any lengthened discussion, as it was in fact only carrying out what the Society arranged to do at their annual meeting. It was proposed to appoint a small committee of three members to see whether they could get the Journal supplied any cheaper and also to see how their funds stood, and what difference the supply or non-supply of the Journal would make. He would suggest that the committee be requested to report to the Council at its January meeting.

Mr. Hayes seconded the resolution, which was carried. The committee to include Mr. Allen, Mr. Hodgson, and the proposer and seconder.

The President said it would be well that the licentiates of the Society should know that an impression which was very general, namely, that the original members were supplied gratuitously with the Journal, was incorrect. He had received some letters from which it would seem that such an impression was entertained, but it was quite erroneous.

The reports of the Examiners for the October examinations were laid before the Council. Of ten candidates who presented themselves for the Preliminary examination, eight passed and two were rejected. Nine candidates presented themselves for licences, of whom eight passed, and the Examiners had referred the case of the remaining candidate to the Council to decide what should be done.

The President said the gentleman in question had failed to make the minimum marks in pharmacy, and according to the rules must be rejected. The Examiners think (and in his opinion justly) that they should have some discretion by vote of the majority in rejecting candidates, even where the minimum marks have been obtained, and should not be tied up by a hard and fast rule.

The Registrar was directed to inform the candidate in question that he was rejected.

The President proposed the admission of the following as members of the Society:—Mr. Cunningham, 11, Upper Baggot Street; Mr. J. S. Short, Upper Baggot Street; and Mr. Donovan, Shelborne Road, Ball's Bridge.

Mr. Hayes proposed the admission of Mr. Crinion, of 67, Talbot Street.

Mr. Hodgson proposed the payment of several accounts, amounting altogether to £118 10*s.* 3*d.*, for requisites supplied for the new offices of the Society.

The motion was agreed to and the Council adjourned

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The third general meeting of the thirty-fifth session was held at the Royal Institution, on Thursday evening, November 8, 1883. The President, Mr. Edward Davies, F.C.S., F.I.C., in the chair.

The minutes of the previous meeting were read and confirmed, and the following donations were announced:—The Smithsonian Reports for 1881, from the Smithsonian Institution, Washington, U.S.A.; eleven pamphlets on Chemical and Philosophical subjects, from the Royal University of Norway, Christiania, Norway; the November number of the *Analyst*; the *Chemical News* for October (four numbers); the *Pharmaceutical Journal*, for October 27 and November 3, from the Society; and 'The Proceedings of the Liverpool Architectural Society—Session 1881–1882,' from the Society.

Mr. A. C. Abraham read a letter he had received, addressed to the Secretary of the Association, from Mr. George Hamilton, of Liscard, drawing attention to a letter of his, on "Colliery Explosions and High Tides," which appeared in the *Liverpool Mercury*, of December 22, 1881, as bearing on the recent colliery explosions.

Mr. Davies, Dr. Symes and Mr. Abraham having discussed this question, the President called upon Mr. Alfred Smetham, F.C.S., to read his paper on "Soap Manufacture and the Soaps of Commerce." The paper will be printed in a future number of this Journal.

Dr. Symes proposed a vote of thanks to Mr. Smetham for his very interesting paper, which was seconded by Mr. A. C. Abraham.

The discussion was continued by Messrs. Parkinson, Conroy, Tinniswood, Mason and Davies, and Mr. Smetham having briefly replied, the motion was put from the chair and carried by acclamation.

There was a considerable attendance of gentlemen connected with the soap trade, who listened to the proceedings with much interest.

The President announced that the annual associated *soirée* would take place on December 19, and that the Honorary Secretary would be glad to receive the names of intending exhibitors thereat.

REGISTERED CHEMISTS' TRADE ASSOCIATION OF LIVERPOOL.

The annual dinner of the Liverpool Registered Chemists' Trade Association was held on Thursday, November 15. The President of the Association, Mr. Charles Symes, Ph.D., occupied the chair.

After the toast of "The Queen and Royal Family" had been drunk, the Chairman, in proposing the toast of the evening, "The Registered Chemists' Trade Association of Liverpool," coupled with the name of Mr. Hocken, Honorary Secretary, remarked that the Association sprang into existence some eight years ago, for it was thought for a city like Liverpool to be without any organization to represent the interests of their trade in any emergency was a discredit. After shortly recounting the good which the Association had already done in maintaining the rights of chemists and druggists, he went on to say that they still wanted a larger number of the members of the trade throughout the city to sympathize with them, for after all, unity was strength. He was pleased to couple the name of the Secretary with the toast, because that gentleman had devoted a large amount of his time to their interests.

Mr. Hocken, in responding, said that all that he had done had been done with hearty goodwill, and with the desire to make the Association a success. He was pleased to see such a large representation of the trade present, but, as he also saw a number of non-members of the Association, he was happy to be in a position to cordially invite them to become members.

The toast of "The Pharmaceutical Society of Great Britain" was given by Mr. Mackinlay, and responded to by Mr. Warhurst. "The Chemists and Druggists' Trade Association of Great Britain," "The Liverpool Chemists' Association and other Kindred Societies," "The Wholesale Trade," and "The President" were proposed and responded to in a hearty manner.

MANCHESTER CHEMISTS AND DRUGGISTS' ASSOCIATION.

The fifteenth annual meeting took place on Monday evening, Nov. 12. Mr. W. Wilkinson, Vice-President, in the chair.

The annual report was read by Mr. Benger, Honorary Secretary, and the statement of accounts by the

Honorary Treasurer, Mr. Woolley. Officers were re-elected, Mr. W. Elborne, of Owens College, being associated with Mr. Benger as joint Honorary Secretary.

A cordial vote of thanks was passed to the Council of the Pharmaceutical Society for weekly copies of the *Pharmaceutical Journal* and for a collection of cinchona barks.

On the motion of the Chairman, seconded by Mr. Benger, it was resolved to alter the title of the Society to "The Manchester Pharmaceutical Association," and it was decided to hold the first ordinary meeting of the session at the Owens College, permission to do so having been kindly given by the college authorities. On this occasion an address will be delivered by Mr. W. Elborne, Lecturer on Pharmacy in the college, and visitors will be afforded an opportunity of inspecting the new pharmaceutical laboratory and materia medica collection.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A meeting of this Society was held on November 15, Dr. Perkin, F.R.S., President, in the chair.

The following certificates were read for the first time:—Messrs. W. P. Bloxam, G. C. Chambers, A. Cobb, A. E. Ekins, F. P. Haviland, W. H. R. Kerry, F. Keeling, J. J. Pilley, J. Phillips, M. Percy, A. W. Rogers, A. Smithells, W. J. Saint, G. Smith.

It was announced that a ballot would take place at the next meeting, December 6.

Mr. C. O'Sullivan then read a paper—

On the Estimation of Starch.—The author has used the method described below during the last eight or ten years for estimating starch in cereals and malted grain. The method may be briefly described as follows:—The finely ground grain is successively extracted with ether, alcohol (sp. gr. ·90) and water at 35°–38°. The starch in the washed residue is gelatinized by boiling with water, cooled to 60° and converted by diastase into dextrin and maltose; if a quantitative determination of these two products be made, the starch originally present can be calculated. The author describes the method as follows:—About 5 grams of the finely ground flour are introduced into a wide-necked 100 c.c. flask and just saturated with alcohol, sp. gr. 0·82; 20 to 25 c.c. of ether being added. After standing several hours with occasional shaking the ethereal solution is decanted through a filter, and the residue in the flask washed with ether. To the residue there is added 80–90 c.c. of alcohol, sp. gr. 0·90, and the mixture warmed to 35°–38° for a few hours; the alcoholic solution is then decanted through the same filter and the residue washed with alcohol (sp. gr. 0·90) at 35°–38°. The residue in the flask and on the filter is washed into a 500 c.c. beaker and the beaker filled with water; in about twenty-four hours the solution is decanted through a filter and the residue washed with water at 35°–38°. The residue in the beaker and on the filter is washed with a short camel-hair brush and a fine jet into 100 c.c. beaker. The whole is then boiled for a few minutes in the water-bath, with constant stirring, to gelatinize the starch, the beaker and its contents are cooled to 62°–63° and about 0·03 gram of diastase added; the digestion at 62° is continued for an hour. The beaker is then boiled for eight to ten minutes; the solution filtered into a 100 c.c. measuring flask; the residue carefully washed with successive small quantities of boiling water and the whole made up to 100 c.c. at 15·5°. The ether frees the grains from fat, etc., the alcohol (·90) removes the sugars, albumenoids other than casein, etc., whilst water at 35°–38° dissolves out the amylams. Dextrin and maltose are the sole products of the action of diastase on starch. The diastase is prepared as follows:—Two to three kilos of finely ground pale barley malt are mixed with sufficient water to saturate and cover the whole. After standing three or four hours the mass is squeezed with a filter press. If not bright the liquid is filtered. To the clear solution alcohol, sp. gr. 0·83, is added as long as a flocculent precipitate falls; as soon as the supernatant liquid becomes milky the addition of alcohol is discontinued. The precipitate is washed with alcohol 0·86–0·88, dehydrated with absolute alcohol, pressed and dried *in vacuo* over sulphuric acid until its weight is constant. Diastase thus prepared is a white, friable, easily soluble powder which retains its activity for a considerable time. Five grams of barley flour thus treated with 0·03 gram diastase gave 100 c.c. at 15·5°, having sp. gr. 1·01003, which represents 25·39 grams of solid matter (taking 1·00395 as the sp. gr. of a solution containing 1 per cent. of starch products); 9·178 grams of this solution reduced 0·241 gram cupric oxide and 200 mm. of it gave a deviation in the Soleil Wentzke-Scheibler saccharimeter of 21·1 divisions. Thus we have $0·241 \text{ gram} \times ·7256 = 0·1748$ gram maltose in 9·178 grams; in the 100 c.c. or 101·003 grams there are 1·923 grams maltose; 1 gram of maltose in 100 c.c. gives a deviation in 200 mm. of 8·112 division, and 1 gram of dextrin in 100 c.c. gives 11·56 div. so $1·923 \times 8·02 = 15·422$, the optical activity of the maltose, and $21·1 - 15·422 = 5·678$, the optical activity of the dextrin, therefore in 100 c.c. there are $\frac{5·678}{11·56} = 0·491$ grams of dextrin. We have, therefore, in the 100 c.c. maltose, 1·923 gram; dextrin, 0·491 gram; diastase, 0·03 gram = 2·444 gram out of 2·539 solids as indicated by the sp. gr.; of this deficiency of 0·095 gram, 0·083 proved to be α-amylam which had not been washed out. One part of starch yields 1 part of dextrin and 1 part of starch yields 1·055 maltose. The starch represented by the above numbers is, therefore, dextrin = 0·491, maltose $\frac{1·928}{1·055} =$ 1·822, or a total of 2·213 grams of starch from 5 grams of barley. Barley thus contains 46·26 per cent. of starch, a second experiment gave 46·38 per cent. The author gives many other determinations in detail:—Barley malt contains 39·9 per cent.; wheat, 55·4 per cent.; wheat malt, 43·26 per cent. and 43·53 per cent.; rye, 44–46 per cent.; rice, 75·77 per cent.; maize, 54–58 per cent.; oats, 35–38 per cent. In some experiments the author estimated the starch in a sample of pure starch containing 89·36 per cent. of dry starch. He obtained 87·72 per cent. and 89·54 per cent. The author states as the result of his experience with the method, that the difference in results obtained by any two observers need not exceed 0·5 per cent. of the total starch.

Dr. Armstrong said the paper was one of great value and the amount of work involved was not by any means represented by the length of the paper. The progress of physiological chemistry must depend upon the accuracy of the means at our disposal of estimating the various constituents. Such researches must contribute a great deal to the investigation of vital problems.

In answer to Dr. Armstrong, Mr. O'Sullivan stated that methylated spirit could be used in the extraction of the flour.

Dr. Percy Frankland then read a paper—

On the Illuminating Power of Ethylene when burnt with Non-luminous Combustible Gases.—The ethylene was prepared from methylated spirit and strong sulphuric acid, and purified by passing over various absorbents; it contained CO_2, 0·05; O, 0·94; C_2H_4, 97·52; N, 1·49. The non-luminous combustible gases experimented with were hydrogen, prepared as usual from zinc and sulphuric acid, carbonic oxide from potassium ferrocyanide and strong sulphuric, and marsh gas. The product obtained by heating sodic acetate and soda lime was so impure that the author was obliged to prepare pure marsh gas by decomposing zinc methyl with water. The illuminating power was determined by an Evan's photometer, a Referees' burner and sperm candles being used; a sample of the gas was always taken at each determination and analysed. The illuminating power of ethylene, supposing 5 cubic feet per hour could be burnt, was found to be 68·5 candles. The illuminating power of ethylene when mixed with hydrogen shows an almost uniform diminution from 68·5 to zero when 90 per cent. H is used; a mixture containing 25 per cent. of ethylene had an illuminating power of twenty candles. In every case the illuminating power of mixtures of ethylene and carbonic oxide were found to be less than that of the corresponding mixtures of ethylene and hydrogen. With marsh gas it was found that mixtures rich in ethylene had about the same luminosity as those containing hydrogen and carbonic oxide, but that the iluminating power of mixtures rich in marsh gas greatly exceeded that of the corresponding mixtures with the two other gases. The intrinsic luminosity of the ethylene, calculated for a uniform consumption of 5 cubic feet per hour, continually increases as the percentage of marsh gas arises. Thus the ethylene in a mixture containing 92 per cent. of marsh gas gives a light of 175 candles, calculated for 5 cubic feet consumed per hour. The high illuminating power of coal gas, considering the small quantity (4·51 per cent.) of illuminating hydrocarbons that it contains, is probably explained by this great value of marsh gas as a diluent. The explanation of this behaviour of marsh gas is to be looked for in the quantity of heat developed in its combustion. Thus 1 mol. of H yields 68,924 units of heat; of CO, 67,284 units; of marsh gas, 209,008 units. The author promises some further experiments on the effects of incombustible diluents.

Dr. Frankland many years ago had made somewhat similar experiments, and had then stated that marsh gas was a diluent and gave no illuminating power to coal-gas. He experimented with a fish-tail burner. There seemed to be no doubt that the apparent rise of 4 to 5 candles in the illuminating power of coal gas by the wonderful "Referees' burner" was largely due to the development of the illuminating power of the marsh gas. For lighting purposes much marsh gas was objectionable, from the CO_2 produced and the quantity of heat developed; but where gas was used for heating purposes the case was quite different, and a large percentage of marsh gas was most advantageous, owing to its great heating power.

Mr. G. S. Johnson then read a paper—

On the Products of Decomposition of Aqueous Solutions of Ammonium Nitrite.—The main points of interest observed are as follows:—No oxide of nitrogen is formed by alkaline solutions of pure ammonium nitrite. Nitrogen is evolved from such solution at temperatures below 100° C., the evolution is facilitated by the presence of spongy platinum. Pure nitrogen can be obtained by adding crystallized cupric chloride to solutions at the ordinary temperature. If solutions of ammonium nitrite be acidulated 40 per cent. of nitric oxide is evolved. The author states that 2 per cent. of the gas evolved by the action of cupric chloride consists of nitrogen in a peculiarly active state, setting free iodine from hydriodic acid, and forming ammonia when mixed with hydrogen and passed through a red hot tube with spongy platinum. This active nitrogen is decomposed at a red heat and is not produced if the temperature of the solution is raised above 90°.

Dr. Armstrong suggested that the nitrogen should be made in some other way; he did not think that passing the evolved gas over red hot copper ensured the absence of oxygen. The quantity of ammonia formed was extremely minute; it seemed also excessively improbable that such an active form of nitrogen should exist.

Dr. E. B. Schmidt then read a short paper—

On the Estimation of Iron by Potasssum Bichromate.—The author recommends the above process; but states that zinc should not be used to reduce the iron, as it interferes with the end reaction with potassium ferricyanide. He prefers Kessler's method of reduction with stannous chloride. The author considers the reduction with sulphite of sodium tedious.

Mr. Riley said that the bichromate method was almost universally used for the estimation of iron; the difficulty when zinc was employed was also well known. Numerous analyses were constantly being made in his laboratory, the reducing agent employed being sodium sulphite. The whole subject was thoroughly discussed by him in a paper published some time back in the *Chem. Soc. Journ.* (1877, vol. ii., p. 24, and 1862, xv., 311).

The Society then adjourned to December 6.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

The first meeting of the present session was held on Thursday, November 15. Professor Attfield, F.R.S., President, in the chair.

The election of officers for the session was proceeded with. Messrs. F. Ransom and R. J. MacDermott were appointed as scrutineers to examine the voting papers. The following members were elected as officers for the present session:—Vice-Presidents, Mr. H. G. Greenish and Mr. T. S. Dymond; Honorary Secretary and Treasurer, Mr. Wyndham R. Dunstan; Assistant Secretary, Mr. F. W. Short; other members of the Executive Committee, Messrs. F. McDiarmid, W. H. Ince, R. W. C. Pierce and P. L. Huskisson.

Mr. Joseph Ince then delivered an address upon "Science: its Abuse and Use," which will be printed in the next number of this Journal.

At the conclusion of the address, Mr. R. W. Giles proposed and Dr. Senier seconded a vote of thanks to Mr. Ince, which was supported by the President and Secretary, and Messrs. Parker and Ransom, and upon being put to the meeting was carried unanimously with much acclamation. The meeting, which was very largely attended, then adjourned.

BRITISH PHARMACEUTICAL CONFERENCE.

(*Concluded from page* 398.)

The next paper was on—

The Composition of Easton's Syrup.

BY ROBERT H. DAVIES, AND EMIL B. SCHMIDT, PH.D.

During a recent examination of some samples of this syrup, the proportion of alkaloid present was found, in some cases, to differ from that prescribed in such a marked manner that a more detailed examination was undertaken with a view of drawing the attention of pharmacists to the variations of strength occurring in this preparation.

Easton's syrup professes to contain "about 1 grain phosphate of iron, 1 grain phosphate of quinia, and $\frac{1}{32}$ grain phosphate of strychnia in each fluid drachm. This statement is made by Mr. Squire,* and a formula given for making the syrup, which is called "Dr. Easton's formula."

Proportion of Quinia Phosphate.—If the directions given here are carefully followed, the product will measure between 24 and 24½ fluid ounces, and will contain the quinia phosphate derived from 192 grains of sulphate. Approximately, then, 1 grain sulphate of quinine has been used in the production of 1 fluid drachm of syrup. The formula of quinia phosphate corresponding to the soluble or neutral sulphate would be $(C_{20}H_{24}N_2O_2)_3,(H_3PO_4)_2$. We may assume with a high degree of probability that this is the phosphate present. One hundred grains of sulphate would yield nearly 87·5 grains of phosphate; therefore under the most favourable circumstances the syrup could not contain more than 0·875 grain of phosphate of quinia per fluid drachm. The amount of

* 'Companion to the British Pharmacopœia,' 13th edit., p. 148.

this latter in a sample of syrup prepared in accordance with Dr. Easton's formula, deduced from the amount of alkaloid extracted, was 0·814 grain per fluid drachm, that is, 6·51 grains per fluid ounce, whereas in various other samples of commerce the amount of phosphate of quinia was as follows:—

Sample of Syrup.	A	B	C	D	E	F	G	H	J	N	Own.	Theory.
Grains of phosph. of quin. per fluid oz.	1·57	7·83	6·54	6·58	4·95	3·15	5·80	7·13	2·72	4·59	6·51	6·87

A certain sample, which was prepared in accordance with the Pharmacopœia of the United States, yielded alkaloid corresponding to 8·56 grains quinia phosphate per fluid ounce.

Mode of Estimation.—10 c.c. of the syrup were mixed, in a separating funnel, with 20 c.c. dist. water, 3 c.c. liq. ammon. fort. added, and, after shaking, 25 c.c. of a mixture of equal volumes of chloroform and ether, and the whole agitated for three or four minutes. After complete separation of the aqueous and chloroformic solutions the latter was drawn off, and passed through a small dry filter into a weighed beaker. When this treatment had been repeated with 20 c.c. of the ether-chloroform mixture to extract any remaining alkaloid, the united ethereal liquids were evaporated by immersing the beaker into a warm water-bath. The residue was finally dried in the air-bath at 100° C. and weighed.

The residual alkaloid should be resinoid in character; if crystalline, it is highly probable that the quinine employed was contaminated with other alkaloids. When dried at 100° C., it should weigh 0·128 gram of which 0·0057 gram is to be deducted for strychnia, leaving 0·1223 gram from 10 c.c. syrup, which corresponds to 6·51 grains of phosphate of quinia per fluid ounce, the quantity which was experimentally obtained from a carefully and freshly prepared sample of syrup. The alkaloid extracted from the same commercial specimens varied from 0·034 gram to 0·152 gram per 10 c.c., the theoretical yield being 0·135 gram per 10 c.c.

Proportion of Ferrous Phosphate.—In producing the 24 fluid ounces of syrup by Dr. Easton's formula, we are directed to decompose 300 grains sulphate of iron with 360 grains phosphate of soda. Mr. Squire mentions that the quantity of sodium phosphate is not sufficient to precipitate the whole of the iron. As a matter of fact, if the 300 grains were entirely converted into phosphate, they would only form 128 grains of ferrous phosphate, $Fe_3, 2PO_4$, which would give a maximum of $5\frac{1}{3}$ grains per fluid ounce, instead of the 8 grains as given in the formula. But even that amount of $5\frac{1}{3}$ grains per fluid ounce is most probably not reached, since in the process of decomposition a quantity of sulphuric acid becomes liberated, which doubtless prevents a portion of the ferrous phosphate from being precipitated.

Mode of Estimation.—We have not succeeded so far in separating iron in the ferrous condition from any that may be present in the ferric state. The results given as ferrous phosphate assume that the whole of the iron present is present as this salt.

Five c.c of the syrup are evaporated on a water-bath in a platinum dish, then carefully incinerated, the ash extracted with hot hydrochloric acid, and washed on a filter; the ferric chloride in the hot filtrate is reduced by solution of stannous chloride, which is added until the solution becomes colourless. Excess of this reagent is removed by the addition of mercuric chloride, and the amount of ferrous salt determined by titrating with a half decinormal solution of potassium bichromate.

The amount of iron present in the samples examined would be equivalent to the following proportions of ferrous phosphate.

Sample.	A	B	C	D	E	F	H	J	Own.	Theory.
Grains of ferrous phosph. per fluid ounce . . .	0·97	1·99	12·32	8·46	7·2	8·72	6·89	8·72	4·7	5·3

The amount present theoretically is 5·3 grains, and that found in the sample made by us, was 4·7 grains per fluid ounce.

Proportion of Strychnine.—The small proportion in which strychnine is present in this preparation, rendered it necessary to depart from the usual mode of extracting and weighing the alkaloid. We had recourse therefore to a colorimetric method for the approximate estimation of this alkaloid, when it is present in very small quantity.

The alkaloidal residue from 10 c.c. of syrup was dissolved in 31·25 c.c. of water acidulated with sulphuric acid, 1 c.c. normal acid was employed, and 5 drops of this solution were added to 4 c.c. of concentrated sulphuric acid tinted yellow with potassium bichromate. The depth of colour produced after standing five minutes, was then compared with the colour produced by known quantities of very dilute solution of strychnia of known strength in the same sulphuric acid coloured with bichromate.

This method was devised about two years ago by Mr. Oscar Eckenstein, in conjunction with one of us. By operating as above it is possible to detect strychnine in one drop of a solution of strychnine one-fiftieth the strength of the official liquor strychniæ, that is containing 1 of strychnine in 5500 about. As a quantitative method it leaves much to be desired.

The results yielded led to the following conclusion:—

Sample.	A	B	C	D	E	F	G	H	J	N	Own.	Theory.
Grains of strychnine in 4 fl. oz..	1 to 1·2	3	·8 to 1	·6 to ·8	·8 to 1	·6 to ·8	·6 to ·8	1·2	·6 to ·8	·6 to ·8	·8	1

The sample prepared by us showed ·8 grain in 4 fluid ounces; by this test theoretically 1 grain should be found in this quantity.

In connection with these results it must be borne in mind that the method as a quantitative one is only approximately correct.

The only sample with which we would find fault on account of the strychnine is sample B., where it would appear that about three times the amount is present that ought to be found.

Phosphoric Acid.—Qualitative testing for sulphates having shown that these were not present in any case in more than traces, and chlorides being proved absent, the total free acid was estimated by means of volumetric solution of soda, and the proportion which might be considered to be in combination with the alkaloids present having been added, the whole calculated as phosphoric acid.

A singular circumstance is to be observed in effecting this estimation: when about five-sixths of the soda solution necessary has been added, and indeed, from this period until the end of the operation, the liquid distinctly reddens blue litmus paper, and at the same time colours red litmus paper blue. To the blue paper the liquid behaves as an acid solution, whilst to the red paper it is alkaline in character with almost equal distinctness. It is impracticable to employ a solution of litmus, and, using litmus paper, the operation may be considered finished when both colours undergo, as far as possible, the same amount of modification.

Ten c.c. of the sample diluted to 50 c.c. required from 4 to 11 c.c. of normal solution of soda; this corresponded to the following proportions of phosphoric acid present.

Sample.	A	B	C	D	E	F	G	H	J	Own.	Theory.
Grains phosphoric acid in 1 fl. oz. .	19·36	20	33·56	46·24	49·24	43·44	48·24	46·6	47·76	37·68	38

A sample made by us yielded 37·68 grains per fluid ounce, and the theoretical amount is 38 grains.

The results given above, together with the specific gravity of each sample, have been tabulated for convenience. The samples examined were obtained in the ordinary way of business from makers or retail dealers In our opinion their varied composition points conclusively to the desirability of some official and authoritative formula for the manufacture of this important preparation.

Table of Composition of Easton's Syrup.

Sample.	Theory.	Own sample.	A.	B.	C.	D.	E.	F.	G.	H.	J.	N.	
Quinia phosphate	6·87	6·51	1·57	7·83	6·54	6·58	4·95	3·15	5·8	7·13	2·72	4·59	Grains per fluid ounce.

A vote of thanks to the authors having been carried,

Mr. PLOWMAN said it appeared from the perusal of this paper that no method had been proposed for separating the cinchona alkaloids one from the other. The residue from the mixture of chloroform and ether had been taken as pure quinia, and this seemed to him to be a serious blemish in the paper.

The next paper was on—

THE ODOROUS PRINCIPLE OF HENBANE LEAF.

BY A. W. GERRARD, F.C.S.

A few years ago some fresh henbane leaves I received particularly attracted my attention by their unusually strong but very characteristic odour. As nothing appeared to be known or published concerning this odorous body, I felt a desire to attempt its extraction and investigate its characters. The leaves being required for the preparation of hyoscyamine I could not follow the usual method of distillation for fear of injury to the alkaloid, so I attempted the separation of the odorous principle by the following process, which proved a success.

Process of Extraction.—The leaves in separate portions were washed in about a litre of ether until 10 pounds had been treated, this yielded a chlorophyll coloured fluid, which was allowed to spontaneously evaporate, giving as a residue a semifluid green extract. The extract washed with water to remove adhering alkaloid or other matters was set aside. After the lapse of some months the extract was noticed to have deposited some crystals showing a brilliant irridescence, likewise some granular matter. Deposition was allowed to continue until it appeared arrested. The solid matters were now separated by straining and gentle pressure, and the soft residue purified by several solutions in and separations from ether. In this way I obtained 2·6 grams of substance, which on examination proved to be the odorous principle of henbane.

Properties.—It forms a pale yellow unctuous semi-crystalline mass, having the appearance of a stearoptene. Its odour was that of henbane, at the same time suggestive of butyric acid. Its reaction to litmus was acid, taste acid and slightly acrid; like many essential oils its vapour exercised a bleaching action on cork. It was freely soluble in alcohol, ether, chloroform and carbon disulphide. Heated, it fused and volatilized; its vapour burnt with a yellow smoky flame, leaving a slight carbonaceous residue, which entirely disappeared on further heating. Examined with a lens numerous crystalline plates were observed. It was heavier than water; its sp. gr. taken by floating in sulphate of magnesium was found to be 1061. With strong sulphuric acid it gave a brown colour; strong nitric acid did not appear to affect it.

My suspicions from its odour were that this body might be an ether or compound of butyric acid. A portion was saponified with soda, then treated with hydrochloric acid in excess; the clear acid solution on separation smelt strongly of butyric acid, and gave, when neutralized and treated with cupric sulphate, the green precipitate characteristic of cupric butyrate. The foregoing characters give evidence that the odorous principle of henbane is a butyric ether, or it may be a butyrin, several of which are described in Watts' 'Dictionary of Chemistry' as having properties in general with the body I have obtained.

In addition to the odorous principle I found in the ether residue some fixed fat and a pungent tasting resin.

Practical Bearing on the Pharmacy of Tincture of Henbane.—It is well known that some tinctures of henbane give a turbidity when diluted with water, whilst others do not; also that the tincture gradually loses its green colour, forming a dark deposit. As regards the former it has been stated that the difference is due to the use of annual and biennial henbanes, a tincture of the latter only giving turbidity. This statement is not the fact, as I have found the tincture from both varieties when freshly made equally give turbidity; it is true that a difference is sometimes observed, and may be attributable to the period at which the plant has been gathered, and the extent to which the odorous principle and fat has developed. Many samples of tincture of henbane almost entirely lose their property of becoming turbid with water; this is generally the result of age, for such a tincture will be found to have lost its original green colour and changed to a brown, with formation of the usual dark deposit. Thus deposition and disappearance of turbidity are simultaneous and proportionate. As to the nature of the deposit in the tincture I believe if examined it will be found to consist of a mixture of odorous principle, fat and chlorophyll, the separation of which is slowly effected by the agency of the water in the proof spirit; if this be so, then it is an argument for the use of a stronger alcohol in making tincture of henbane.

A vote of thanks was passed to Mr. Gerrard.

The last paper read was entitled—

SUGGESTIONS FOR COMBINATIONS OF COLLODION.

BY J. B. BARNES,

Pharmaceutical Chemist.

Having witnessed the good effects of the compound solution of salicylic acid and collodion when applied to corns, as recommended by Dr. Traill Green,* I am disposed to believe that the use of collodion as a medium for the topical application of several other substances might be advantageously extended; already we are familiar with such preparations as collodium epispasticum and collodion stypticum, for which Mr. Martindale, in the 'Extra Pharmacopœia,' gives formulæ as well as

* *Pharm. Journal*, April 28, 1883, p. 884.

for collodium c. oleo crotonis, collodium iodi, and collodium iodoformi.

The advantages of combinations of collodion are that, unlike ointments, they remain fixed for some time to the part applied, and are cleanly. It remains, however, to be proved whether the remedial effects of the several substances in combination with it will be obtained; collodion must retard the action more or less of all of them, but at the same time it is reasonable to expect some of those under consideration may be found useful. It is not for the pharmacist to determine the strength of such combinations,—that has to be decided by the prescriber,—but it is within the province of the former to discover by experiment the proportions suitable for combination.

I find when wood tar is mixed in the proportion of 1 drachm by weight with 4 of collodion a perfect solution is effected, which, when applied to the body, dries quickly and leaves a smooth covering.

Coal tar collodion may also be prepared by mixing, in the same proportions, an alcoholic extract of coal tar of the consistence of syrup with collodion; it is fluorescent in appearance, and forms a good covering when applied to the skin. The addition of 30 grains of iodine to the fluid ounce of either of these preparations does not affect its consistency or adhering properties.

Oleum picis juniperi, when mixed in the proportion of 1 by weight to 5 of collodion, dissolves and forms an application which when applied to the skin dries quickly, leaving a good covering.

Oil of gurgun, in the proportion of 1 by weight to 3 or 4 parts of collodion, also dissolves and forms a good varnish.

Oleic acid and Peruvian balsam, each in the proportion of 1 by weight to 4 of collodion, form good varnishes when applied to the skin, which require ether to remove them.

The following also form suitable combinations for painting on the skin, adhere firmly and do not crack. Glacial acetic acid, 1 part by weight; flexible collodion, 4 parts; carbolic acid, in crystals, 1 part to 4 of flexible collodion; creasote, 1 part by weight to 7; and essential oil of mustard, 1 part by weight to 7 of flexible collodion.

Belladonna collodion may be prepared by macerating 60 grains of the alcoholic extract in a fluid ounce of flexible collodion for twenty-four hours and decanting the clear liquid; when spread upon the body it leaves a smooth surface.

Aconitia, atropia, hyoscyamia and veratria dissolve very readily in collodion, the latter alkaloid in the proportion of 8 grains to 7 fluid drachms of flexible collodion and 1 fluid drachm of oleic acid; when applied to the skin leaves a smooth covering, which does not rub off.

Morphia does not dissolve in collodion, but when in combination with oleic acid it does; 5 or 10 grains in a fluid drachm of the acid with 7 drachms of flexible collodion forms a covering which adheres firmly to the skin.

Ammoniated mercury, iodide of lead and precipitated sulphur, each of them mixed with flexible collodion in the proportion of 1 drachm to 7 and 4 or 5 drops of castor oil, form mixtures which adhere firmly to the skin.

Oleate of mercury mixed with collodion in the proportion of 1 to 4, when extended on the surface of the body, leaves a smooth almost transparent covering.

In the preparation of the oleate 1320 grains of oleic acid was diluted with three volumes of ether; 420 grains of dry binoxide of mercury was added, and the mixture shaken occasionally for four days until the orange colour of the binoxide had disappeared, the white creamy compound was allowed to evaporate without the application of heat. The dilution of the oleic acid with ether prevents caking, the oleate of mercury so obtained is of a yellowish-white colour, of the consistence of vaseline.

Oleate of zinc mixed in the proportion of 1 part to 4 of collodion forms a convenient mixture for topical application.

Iodide of cadmium dissolves in flexible collodion, 1 drachm mixed with 7 fluid drachms of the collodion and 4 drops of castor oil, gives a colourless bright solution, which, when painted on the skin, leaves a smooth white covering.

I have not been successful in preparing a smooth transparent collodion of iodide of sulphur, the iodine dissolves out and the sulphur subsides; 50 grains of iodide of sulphur treated with ether yielded 10 grains of sulphur, the exact proportion given in the Pharmacopœia as obtainable when 50 grains of the iodide is boiled with water and the iodine driven off.

My sample of this substance obtained from a firm of well-known manufacturing chemists was now mixed in the proportion of 1 to 60 of glycerine, it appeared to dissolve, but the sulphur gradually subsided.

A vote of thanks was passed to Mr. Barnes.

General Business.

Mr. Plowman said he rose to perform a very pleasant task. It was hardly necessary to inform the members of the Conference that through the generosity of Mr. Thomas Hyde Hills a fund had been provided for giving a number of books to be given to the Associations of those towns where the Conference might meet from time to time. In the case of Southport there had been, up to the present time, no Association, and hence some little difficulty arose; but after correspondence between the secretaries acting for the Executive Committee and the Southport authorities, it was decided that the books should be granted on condition that they should be taken care of by the local secretary of the Pharmaceutical Society for the time being, and that they should form the nucleus of a library. The books were now on the table for formal presentation to Mr. Ashton, and he could only express a hope that the library would grow as rapidly and with the same signs of permanence as the town of Southport. He must add that besides the Bell and Hills gift were two volumes given by Mr. Thomas Hanbury in memory of his brother, Mr. Daniel Hanbury, namely, 'The Science Papers,' and 'Pharmacographia.'

Mr. Ashton, on behalf of the pharmacists of Southport, begged to heartily thank the committee and trustees of the fund for this gift. According to the arrangements made there was every prospect that in a little time the number of books would be considerably augmented, and he was sure they would be much appreciated by the chemists of Southport.

Place of Meeting for 1884.

Mr. Benger said the members were aware that it was the custom of the Conference to accompany the British Association to its various places of meeting. They would also remember that last year, when it was decided the British Association should go to Canada next year, it was felt that it would not be wise to attempt to follow them on that occasion. Hearing of this, the chemists of Aberdeen and the North of Scotland forwarded a cordial invitation to go there next year. A good deal of correspondence took place and arrangements were almost completed, but within the last few days a new aspect of affairs had arisen. The British Association, it was understood, would probably go to Aberdeen in 1885, and under those circumstances the Aberdeen chemists had withdrawn temporarily their invitation, so as to give the Pharmaceutical Conference an opportunity of accompanying the British Association when it did go there. They were not, however, left homeless. The President had previously had some correspondence with a gentleman in the South of England, and having heard that they were now open, he had sent in the name of the chemists of Hastings and St. Leonards a very cordial invitation to the Conference to meet there next year. Having read the letter of invitation, Mr. Benger concluded by moving that this cordial invitation be as cordially accepted, and he hoped that the meeting might prove as satisfactory in the South of England as the present one had in the North.

Dr. Quinlan seconded the proposition.

The President, in putting the resolution, explained that the invitation was quite spontaneous; it had been made to him privately some two months ago, but it was then held in abeyance owing to the expectation that they would go elsewhere. It had now been renewed in the cordial spirit which they had heard from the letter.

The resolution was carried unanimously.

Election of Officers.

The President said the Executive Committee had now to present the list of suggested names of officers for the ensuing year. As he had before stated, the Committee had done its best to select the names of those who would be likely best to serve the Conference, but at the same time any member was quite at liberty to suggest any other names.

Mr. Benger explained that one or two blanks were left for local officers who would be appointed by the Executive Committee later on, if that met the approval of members.

A resolution was accordingly passed unanimously, entrusting to the Executive Committee the duty of appointing local officers for the ensuing year.

The list of names suggested having been read, Mr. Nesbit and Mr. Chipperfield were appointed to act as scrutineers.

Mr. Stephenson (Edinburgh) then moved:—

"That the cordial thanks of the non-resident members of the British Pharmaceutical Conference be given to the Local Committee, and especially to Messrs. Radley, Ashton, Ball, and Kershaw, for the very successful manner in which the various arrangements connected with the Southport visit have been carried out."

He was sure the Executive Committee had correctly gauged the feelings of the meeting in giving priority to this resolution, and possibly the same feelings of propriety had influenced them in assigning it to his hands he being a comparative stranger among the non-resident visitors. The welcome they had received from the pharmacists of Southport, the kindness and hospitality which they had experienced and further expected to experience were so marked, that it was quite unnecessary to say a single word in support of the resolution. The members of the different localities where the Conference met seemed to vie with each other in hospitality, so that it would be a difficult matter for any town to surpass previous efforts; but without making any invidious comparisons, he might express his own feelings that the Southport people had quite held their own, and it must be very gratifying to them to know that this had been without exception the most successful meeting in point of numbers which the Conference had yet held.

Mr. Taylor had the greatest pleasure in seconding the resolution so ably moved by Mr. Stevenson.

Mr. Benger said he had had rather special opportunities of coming in contact with members of the Committee, having had occasion to visit Southport several times during the past year. He could only say that so far from having to use any influence he might possess in the way of stimulus he had rather to act like the guard at the tail of a train, and endeavour occasionally to put on the brake; however, he must say that the brake did not act very well. It would have been a hard thing to check the generous enthusiasm of the Local Committee and their friends.

The President said not only as President, but as one who had been in the town several days before the meeting commenced, he had seen something of the work of the Local Committee. He had been struck with the admirable organization, great enthusiasm, and entire heartiness with which the local members of the Conference had thrown themselves into the work of entertaining the visiting members.

The motion having been carried unanimously,

Mr. Radley (Chairman of the Local Committee) begged to thank the members for the handsome compliment which had been paid them. It was their great wish that the Conference should have a hearty reception, and it would be a very pleasant reflection that their efforts had been so much appreciated. One great advantage which arose out of these Conferences was the very pleasant meetings of the Committee which had taken place, and the introduction of brethren from neighbouring towns to each other. He trusted this would be the starting point of a local association, which might become very powerful for good in the future.

Mr. Ashton (Local Secretary) said it had been a labour of love to all the Committee. They had had many pleasant meetings together, everything had gone on straightforwardly, and he was quite certain that it had been the means of bringing together some gentlemen who were not in the habit of meeting before, and that the same kindly feeling was engendered in every place which the Conference visited.

(The scrutineers here returned and announced that the election was unanimous, only one paper having been slightly altered, and that not to erase any gentleman's name, but to suggest an alteration in his position.)

Officers for 1883-84.

The following is a list of the officers elected:—

President.—J. Williams, F.C.S.

Vice-Presidents.—M. Carteighe, F.I.C., F.C.S., London; J. R. Young, Edinburgh; W. R. Atkins.

Treasurer.—C. Ekin, F.C.S., Hounslow.

General Secretaries.—F. Baden Benger, F.C.S., Manchester; S. Plowman, F.I.C., London.

Other Members of Executive Committee.—J. Borland, F.C.S., F.R.M.S., Kilmarnock; J. C. C. Payne, Belfast; W. A. H. Naylor, F.C.S., London; W. V. Radley, Southport; W. Hills, F.C.S., London; G. S. Taylor, F.C.S., London; J. C. Thresh, D.Sc., F.C.S., Buxton; J. B. Stephenson, Edinburgh.

Auditor.—T. H. Sykes, Southport.

Mr. Brunker said that whilst fully concurring in the vote of thanks which had been passed to the Local Committee he felt that the visiting members would be guilty of a great omission if they were not to express their cordial thanks to the public bodies which had done so much for the entertainment of the visitors. He would, therefore, propose—

"That the best thanks of this meeting be given to the chairman (Ed. Holden, Esq.), the directors, and the manager (Mr. Howorth) of the Victoria Baths Company for their kindness in giving a special swimming entertainment to members of the Conference. Also to the chairman (Ed. Holden, Esq.), the directors, and the manager (Mr. Nightingale) of the Glaciarium Company for granting admission to the Glaciarium and allowing members to inspect the works."

Mr. Naylor seconded the resolution, which was carried unanimously.

Mr. John Williams moved the next resolution, viz:—

"That the hearty thanks of the Conference be accorded to the President for the very able and courteous manner in which he has conducted the business of the meeting."

If he were to say what he should like, and, perhaps, ought to say in support of this resolution he should require a considerable time; but at that late hour he felt sure he should best serve the interests and consult the feelings of the meeting by not attempting to say much. He must say one thing, however, that so ably had the President conducted the business of the Conference, and so much were they indebted to him for the admirable discourse which he had delivered, that it made one tremble to think that whoever followed him must inevitably by comparison fail. For himself he should have to throw himself on the indulgence of the members, and could hardly hope in any way to emulate the admirable performance of the President.

Mr. A. H. Mason said the resolution really did not require a seconder, but simply as a matter of form he would add a word or two. They were not only indebted to Professor Attfield for the ability with which he had presided over the meetings, but, as Mr. Williams had said, for the two able addresses which he had delivered. Most of them would feel that it might have been more congenial to the tastes of Professor Attfield to deliver addresses having a more scientific aspect; but he had sacrificed his own feelings and considered only the position of the members at large in giving these two discourses on the relations of pharmacy to the State, and the relations of the State to pharmacy. When Mr. Kershaw moved a vote of thanks to Professor Attfield the other day, a hint which he took upon himself to ask the meeting to endorse was most enthusiastically received, viz., that a copy of these addresses might be distributed to every member of the House of Commons. If it were necessary that a resolution should be passed authorizing the incoming executive to undertake that work he was sure it would receive cordial approval, but that would not be necessary if the members showed their approbation in the usual way. He might state, also, that it would not be a costly proceeding, the addresses being already in type. If any of them had seen the *Times* of that day they would have noticed a very pertinent article dealing with the address in which the editor took up the position put forward by the President, namely, that pharmacists had to undergo a certain education, etc., for the benefit of the State, and that the State did not provide a *quid pro quo*. An old philosopher said there was nothing like agitation; even butter was made by agitation. The press was taking this matter up, and at the present time it would be most desirable to send a copy of this address to the members of the House of Commons. In conclusion he could only say that it was with extreme regret that he noticed Professor Attfield's name was obliterated from the list of officers handed round, but he was quite sure that although his name was not there his heart would remain with them always.

Mr. Plowman remarked that Professor Attfield still remained vice-president in virtue of having been president, and he would no doubt be present at every meeting of the committee as he had been since the founding of the Conference.

Mr. Schacht, having read an extract from the article in the *Times* referred to, said the machinery for the improved legislation required already existed in the action taken by the Council of the Pharmaceutical Society.

The resolution was then put by Mr. Williams, and carried unanimously.

The President, in response, said he thanked the members from the very bottom of his heart for the most enthusiastic way in which the resolution had been accepted. He thanked his colleagues, and the members generally, for the support they had given him, and he could not have conducted the business so successfully, as it was alleged he had, had he not had the hearty support of his colleagues on the Executive Committee. Each year there had been present gentlemen who had been former presidents, from whose example he had learnt so much, and who had kindly aided him in conducting the meetings. He must not omit to refer to the very great service rendered to him personally as President as well as to the meeting, and to every member of the Conference, by the two General Secretaries, Mr. Benger and Mr. Plowman. He also begged most heartily to thank the authors of the papers. These meetings, were after all, to aid the Conference in its objects of prosecuting researches and promoting good fellowship; the former stood first in the official pages, and he had to thank the authors of papers for coming forward, both last year and this, with such valuable communications. He was very proud to see that so many of the authors of papers had been his own old students. He must also thank all who had attended the meetings. He would not suppose that the very large meetings they had had, attended by more members than had ever attended any meetings before—according to the official record within seven of 200—had been brought about on account of his presiding; but he did know and was happy to acknowledge that many gentlemen had come kindly to support him personally. It seemed to be the desire of the meeting that some arrangements might be made by which his address, or the two addresses forming one subject, should be brought before the notice of members of Parliament, and whilst thanking the members most heartily for the great personal compliment to himself contained in the suggestion, he might say that there was no difficulty in the way of that wish being carried out. The present address was in type, and, through the kindness of the Executive Committee, he had been furnished with a few copies for distribution to the press, and he was glad to see that the distribution already had such useful results. Last year also, having the intention to complete the subject this year by delivering the second address, he took the precaution of having extra copies of the address supplied to him by the printers which could now be bound up with the present one, and circulated as desired, and he could only hope that members of Parliament might make good use of them. Mr. Plowman had drawn attention to the fact that he had been able to give his services to the Conference without one single break for twenty-one consecutive years. He was thankful to have had the health necessary to enable him to do so, for he had, of course, to give up a great part of his holiday every year to carry out this work; nevertheless, although it had been somewhat a strain upon him, it had been a work of love, a labour of pleasure, for he felt that as pharmacy had given to him his position, for he had always been proud to state that he had begun life in connection with science as a pharmaceutical apprentice, he should do from year to year all he could in support of all the objects of pharmacy, and to promote its welfare. Twenty years ago he aided in founding the Conference; that, therefore, made the twenty-first meeting. He had since aided in maintaining the Conference with the help of its numerous supporters, and now he was proud to think he had helped in conducting the last two of its meetings. Although, perhaps, his health would not enable him to be present at every annual gathering in future, they might all rest assured that he should be present whenever possible, and that from his position in London he should no doubt be able, and certainly should be anxious, to attend every one of the Executive Committee meetings. Nevertheless, as one of the elected officers, though he still had a position on the committee, he must now bid a loving farewell to the Conference and to the members, thanking them for the kindness they had shown him.

Correspondence.

Dragon's Blood.

Sir,—In the course of the discussion on our paper on "Dragon's Blood," read before the Pharmaceutical Society, Professor Bentley expressed a wish to know if we had tested for iron in the specimens of dragon's blood examined by us. In answer, we beg to state that we analysed the ash in each case and found iron always present, though not in large quantity. We omitted to give the analyses of ash, as well as many other minor details of our investigation, in order that our paper might not be of undue length.

We would also beg to direct attention to two corrections which are necessary in our paper. On page 363 of the Journal, bottom line, for $(C_{18}H_{17}O)_2Pb$ read $(C_{18}H_{17}O_4)_2Pb$, and on page 364, line 19 from top, for $C_{17}H_{19}O_5$ read $C_{17}H_{18}O_5$.

J. J. Dobbie,
G. G. Henderson.

University of Glasgow, Chemical Laboratory.

Communications, Letters, etc., have been received from Messrs. Brown, Nind, Quinlan, Newsholme, Cooper, Henry, Hick, Pharmacist, Inquirer.

"THE MONTH."

At no time of the year perhaps are there fewer flowers to be found, either in gardens or in the country, whether in the hedgerows, the waysides or the woods, than in November. It is the month of decaying leaves and damp muggy weather, when cryptogams reign supreme, when moulds and fungi perform their functions of effecting chemical changes in the vegetable kingdom, and their near relations, the schizomycetes, are equally active in carrying on pathological changes in the animal kingdom. According to the *Medical Times and Gazette* (p. 522), Dr. C. Kelly, in a succession of able reports, has gone some way towards showing that in most of the rather numerous epidemics of diphtheria which have occurred in his district (West Sussex) within the last few years, a clear connection may be traced between the disease and the moist condition of the air and soil. Certain it is that the damp weather of October and November is most favourable for the development of many of the lower algæ, the red *Protococcus* and the blackish *Oscillariæ* being noticeable everywhere on damp walls and untrodden paths and waysides. This being the case there is every reason to suppose that the decaying vegetable and animal matter of sewers and dustbins is likely to develop at this time of year micro-organisms, as low or lower in the scale of life, at a much more rapid rate than usual, and thus tend to cause the spread of infectious diseases to a greater extent than at other periods.

A Parliamentary paper issued during the last few days contains an extract from the Anglo-Brazilian *Times* which gives some interesting particulars respecting the discovery, by Dr. Freire, of a micro-organism that is alleged to be the cause of yellow fever, to which a brief reference was made last month. According to Dr. Freire the disease is due to the rapid development and multiplication of a *Cryptococcus*, always recognizable in cases of yellow fever, to which he has given the name of *C. xanthogenicus*. In support of his theory he describes the results of a number of experiments. A rabbit inoculated with a drop of blood from the body of a person who had died from yellow fever died shortly afterwards, and a drop of this rabbit's blood caused the death of a guinea pig, the symptoms and lesions being exactly like those associated with yellow fever in man. The inoculation was continued through a series of guinea pigs until the ninth in succession was reached, the disease meanwhile showing rather an increase in virulence than otherwise. The organisms, even when taken direct from a corpse, remained inert after having been heated to 280°, though some taken at the same time, but not so treated, caused death. A guinea pig enclosed in an atmosphere saturated with the organisms died with the symptoms of yellow fever in seven days, whilst another died in one day after vaccination with water that had been in contact with earth from the cemetery, in which there was an abundance of the cryptococci. Dr. Freire is hopeful as to the discovery of a means of combating the disease, and claims to have already succeeded in attenuating its virulence though the cultivation and injection of organisms antagonistic to the yellow fever microbes and by which their development is impeded.

Some further results have been obtained by Messrs. Cornil and Berlioz in their investigations upon the bacilli of jequirity (*Abrus precatorius*). (*Comptes Rendus*, xcvii., 806). It seems that these micro-organisms produce different effects according to the dose employed, the part which is inoculated and the animals upon which experiment is made. In small-sized animals absorption of a small dose through the skin causes local inflammation or gangrene and confers immunity from subsequent inoculation. In larger doses fatal disease follows. When injected into the blood-vessels of the frog an extraordinary growth of the bacilli takes place and causes a virulent malady. The blood of guinea pigs and rabbits does not form so favourable a nidus for their multiplication.

"Salicyl-resorcin-ketone" is a compound which is formed when salicylic acid and resorcin are heated together to 195-200° C., and as might be expected it shares to some extent the antiseptic and antipyretic properties of the bodies from which it is prepared. According to Herr Repond (*Zeits. d. allg. öst. Apot.-Ver.*, xxi., 502), in small quantities it is less powerful as an antiseptic than either salicylic acid or carbolic acid; its action being rather to limit the development of than to kill the septic germs. It is, however, non-poisonous, repeated doses of two grams having been taken without inconvenience; it has been found useful for surgical dressings and has been administered to the extent of three or four grams daily in typhoid fever without producing any unpleasant symptoms. Salicyl-resorcin-ketone is soluble in 1000 parts of water at 40° C., soluble with difficulty in hot water and easily soluble in glycerine and alcohol. It melts at 133°-134° C., gives when in solution a red-brown colour with perchloride of iron, smells faintly aromatic and has a not disagreeable taste. The corresponding compound with phenol, "salicyl-phenol-ketone," is still less active as an antiseptic and more insoluble, but is said to be non-poisonous even in ten gram doses.

Dr. Hassall, in a paper in the *British Medical Journal* (Nov. 3, p. 869), on "Inhalation, more particularly Antiseptic Inhalation in Diseases of the Lungs," publishes the results of his experiments, which show that there is still much room for improvement in the method of employing this form of medical treatment. The conclusion he has arrived at is that there is reason to believe that but a very small portion of the substances employed, as the sprays are at present used, really reaches the lungs themselves, or even the larynx and trachea. This applies more particularly to such substances as carbolic acid, creasote, thymol and iodine; but with respect to others possessing a high degree of volatility, and employed in considerable quantity, the temperature being maintained, he considers that vapour inhalation may be practised in some cases with benefit. It is an interesting fact to place on record that so small a proportion of the remedy used, as he states, is inhaled; but inhalation would doubtless soon go out of fashion if the small quantity of the drug inhaled did not produce the effect required, and the proportion of any remedy necessary to produce its therapeutical effects is apparently, in some cases at all events, much smaller than is generally supposed. The proportion of musk or of other perfumes that is capable of producing a painful or pleasurable effect on the nervous system is extremely minute. It may be hoped, therefore, that Dr. Hassall's further researches will give some information as to the actual therapeutical effect produced by the small quantity of the drugs he mentions as capable of being effectively inhaled by the methods at present in use.

Convallaria majalis still seems to attract a fair share of attention as a remedy for cardiac diseases. Dr. G. Herschell (*Lancet*, Oct. 27, p. 724) mentions a case in which symptoms occurred almost the direct opposite of those that might have been expected from the use of the drug. The patient, who had, however, previously been in the habit of taking digitalis, suffered after each dose of convallaria from a sense of oppression over the sternum, nausea, cold feet, vertigo, flatulence, and a feeling of utter prostration, whilst the pulse became nearly imperceptible at the wrist. The action normally produced by the drug, according to Dr. Lee, is to slacken the beating of the heart, restore its normal rhythm, augment the energy of the systole and increase the blood pressure. Dr. E. Drummond, writing from Rome, points out in the *British Medical Journal* (Nov. 17, p. 970) that the properties of the plant were known in Europe as early as the beginning of the seventeenth century. In an old Italian 'Commentary on the Materia Medica of Dioscorides,' by Dr. Pietro Andrea Matthioli (physician to the Emperor and to the Archduke Ferdinand of Austria), and published in Venice in 1621, he has found the following statement:—"The Germans use lily of the valleys to strengthen the heart, the brain and spiritual parts, and give it in palpitation, vertigo, epilepsy and apoplexy, also as a remedy for the bites and stings of poisonous animals, to quicken parturition, and for inflammations of the eyes. For this purpose they are wont to prepare the wine from the flowers at the time of the vintage, and then infuse them in old wine for forty days in the sun, and subsequently distil and redistil (but not many times) along with lavender flowers, rosemary and other aromatics. They then preserve it as one of the most precious things that are to be found among medicines, and they call it *aqua aurea*, and preserve it in vessels of gold and silver against sudden attacks. They even believe that given *in articulo mortis* it is able to prolong life for several hours. In this, however, they are not unfrequently deceived, as I have myself witnessed." Almost exactly the same description occurs in the 'Botanologia' of Johannes Franckenii, a medical writer of the first half of the sixteenth century, recently published by Dr. R. Fristedt, of Upsala, except that proportions are mentioned and that ten days instead of forty is the time given for allowing the infusion to stand before distillation. However much of the beneficial stimulant effect of the distilled water may have been due to the cinnamon, cloves, cardamoms, rosemary and lavender, it is certain that the lily of the valley must have been classed as a cardiac stimulant, from having been given with other drugs to which similar properties were attributed; a proof of this use of one of the drugs remaining to this day in the spiritus lavandulæ co. of the Pharmacopœia.

Paraldehyd, the new hypnotic, has been the subject of a large number of observations, made by Dr. Langreuter in the Dalldorf lunatic asylum (*Pharm. Cent.*, xxiv., 503). The difficult solubility of the compound and its burning taste rendered its administration difficult, and the formula adopted was:—paraldehyd, 25 grams; ol. menth. pip., gtt. 2; ol. oliv. q.s. ad 50 grams. The ordinary dose was 6 grams of paraldehyd, which produced no abnormal symptoms, with the exception of a slight irregularity of the pulse that rapidly passed away, the pulse becoming somewhat fuller. Sleep followed in from five to thirty minutes after taking the dose, and in two cases the patient sank from the seat in one minute. Quietude was found to favour the best results, sleep ensuing in 90 per cent. of the cases when the medicine was administered in the evening and in 61 per cent. when administered in the day-time. In 61 per cent. of the cases a full night's rest (seven or eight hours) was obtained, and even where sleep was not induced the medicine exercised a calming influence. Experiments were also tried with acetal, but the results were not so favourable, and its use is not recommended by Dr. Langreuter. He found it less powerful in its action than paraldehyd, an average dose from 8 to 10 grams being required, whilst the taste and smell are much more intense and the result is not so constant; nevertheless, although it may not induce sleep it exercises a calming influence on violent lunatics, which chloral hydrate does not. The corresponding doses appear to be: chloral hydrate, 2·5 grams = paraldehyd, 6 grams = acetal, 10 grams. Both paraldehyd and acetal are at present much dearer than chloral hydrate, but paraldehyd can be used where chloral hydrate is contraindicated, in cases where the heart is affected.

Toothache is treated by Dr. Kirchbauer by the internal administration hourly until relief commences to be effected of tablespoonful doses of a mixture consisting of—chloral. butyl., 5·0; glycerin., 30·0; aq. dest., 100·0; syr. cort. aur., 20·0; ol. fœniculi, gtt. 5 (*Pharm. Post.*, xvi., 537). He also uses what he calls "chloral-carbol wadding," which is prepared by steeping purified wadding in a mixture made by allowing equal parts of carbolic acid and chloral hydrate to liquefy together, and keeping the whole in a closed vessel until required for use. A small plug of the medicated wadding is placed in the aching tooth.

Dr. Delbastaille reports (*Pharm. Post*, xvi., 537) that he has treated strumous glands, sarcoma, cancer, etc., with good effect by daily injections of three minim doses of a one per cent. solution of perosmic acid. He states that the surrounding tissues are not affected by the acid. According to the *Lancet* (Nov. 24, p. 919), Professor Bilroth has used a solution of perosmic acid of the same strength as a subcutaneous injection in the treatment of neuralgia, but the dose is not stated.

The use of an ointment consisting of oil of cade, red oxide of mercury, camphor and vaseline has been recommended as a dressing for eczema. It is reported (*Pharm. Post.*, xvi., 537) that in a case where oil of cajeput was erronously dispensed for oil of cade in making this ointment it proved to be a valuable remedy in that disease.

The value of pilocarpine in the treatment of severe hiccough, to which attention was called some time ago in the *Revue Médicale Chirurgicale*, has been confirmed by the success attending its use in a very severe case which had lasted for three months and resisted all other remedies (*Brit. Med. Journ.*, Nov. 17, p. 985). Dr. Ruhdorfer administered a subcutaneous injection of the hydrochlorate of pilocarpine (of the strength of 3 centigrammes in a gram of water) and the hiccough was at once cured, as if by magic, and did not subsequently return.

A solution of chrysarobin in collodion has been recently recommended in the treatment of psoriasis by Dr. G. H. Fox, New York, and several dermatologists have confirmed his statements as to its efficacy. Dr. van Harlingen (*Bost. Med. Journ.*, Nov. 8, p. 440) says that it has one great advantage over the gelatine preparations introduced lately, in that it can be applied extemporaneously, but he has found it so much less active than chrysarobin ointment that he has not been encouraged to continue its use. He prefers to use a 10 per cent. emulsion of chrysarobin in liquor gutta-perchæ, which would be a preparation similar to that described a few weeks ago by Mr. Modlen (see before, p. 341).

Dr. F. C. Berry, of Lynton, has called attention (*Practitioner*, p. 346) to the use of marshmallow in palmar psoriasis. In one case in which Fowler's solution, chrysophanic acid, huile de cade, and other remedies had proved unsuccessful, the disease is said to have been cured in a month by the application of marsh-mallow ointment. The ointment was made by cutting the fresh leaves into small pieces, stirring them together with lard, boiling the mixture for half an hour, and then straining it.

A new therapeutical use of santonin has been recently discovered by accident. Dr. U. Anderson writes in the *Lancet* (Nov. 10, p. 845) that after treating a patient for lumbrici the patient remarked that the medicine had not merely killed the worms, but cured a gleet of long standing. Dr. Anderson recommends for the latter disease, as a dose, 5 grains of santonin rubbed down with 5 grains of sugar of milk and taken twice a day, fasting, in milk.

A case of poisoning by 4½ drachms of chloral and 3 drachms of bromide of potassium is recorded in the *Lancet*, in which the administration of strychnine (although the antidote was given probably ten hours after taking the chloral) caused the return of consciousness in three hours and ultimate recovery. The dose used is not mentioned, but probably the quantity recommended in Dr. Murrell's excellent little work, 'What to do in Cases of Poisoning,' was prescribed. The history of the recovery from so large a dose of chloral would, however, have been enhanced in value had the dose of strychnine that was found so effectual been mentioned.

Dr. Layet, Professor of the Faculty of Medicine of Bordeaux, has lately read a paper (*Lancet*, Oct. 27, p. 740) on some injurious properties of vanilla, which have hitherto not been satisfactorily explained. In storehouses where the pods are cleaned, sorted and classed according to their quality, symptoms of itching of the face and hands, together with a powerful smarting sensation, are experienced, and the skin becomes covered with a pruriginous eruption, followed by swelling and reddening, and desquamation after a few days. Dr. Layet has studied this complaint at a warehouse in Bordeaux, where on an average 25,000 to 30,000 kilogrammes of vanilla are received every year. He finds the above symptoms to be apparently produced by a small white acarus which generally occupies the end of the pod. This insect does not bury itself in the skin like the *Acarus scabiei*, but causes the irritation by mere contact, being probably aided in its irritating effects by the presence of the "givre" or acicular crystals which effloresce on the surface of the vanilla. Another affection produced by the manipulation of vanilla is characterized by a feeling of malaise with dullness, stiffness and muscular pains, which oblige the worker to give up this kind of labour. These symptoms Dr. Layet considers to be probably due to the manipulation of inferior pods of vanilla containing much oily juice enveloping the seeds in the interior of the pod.

Students of materia medica who have perused the 'Pharmacographia' will probably be familiar with the fact that there are two drugs which have been imported into this country under the name of kamala, but that one of these is more correctly known as "wars" or "wurrus," and that it differs from the true kamala in being of a dark purple colour. Hitherto its exact source was unknown, but in part iv., p. 584, of Dr. Dymock's 'Vegetable Materia Medica of Western India,' just issued, it is stated that it is the gland of the leaf of a leguminous plant, *Flemingia congesta*, common in Arabia and India. Singularly enough, it has never been collected, so far as Dr. Dymock has been able to ascertain, in India, nor does it appear to be known as an import from Arabia.

Cusparia bark has been the subject of an investigation by Messrs. Körner and Böhringer, who report (*Ann. di Chimica*, lxxvi., 193) some very interesting results. The bark was extracted with ether and the solution when treated with dilute sulphuric or oxalic acid gave a coloured crystalline precipitate of the corresponding salt of an alkaloid, which after repeated recrystallizations from hot alcohol still formed greenish-yellow crystals. The colour, however, appears to have been due to an impurity, for upon decomposing the salt the free alkaloid was obtained colourless and then formed colourless salts. This alkaloid, which the authors have named "cusparine" and represent by the formula $C_{19}H_{17}NO_3$, melts at 92° C., and when treated with potash splits up into a new alkaloid, melting at about 250° C., and a difficultly soluble substance having the characters of an aromatic acid. The sulphate, hydrochlorate and oxalate of cusparine are slightly soluble in water, the acetate and the tartrate being much more soluble. The ethereal mother-liquor was found to contain the salt of another alkaloid, which when set free and crystallized from petroleum spirit formed slender white needles, fusing at 115·5° C. This alkaloid has been named "galipeine" and is represented by the formula $C_{20}H_{21}NO_3$. The neutral sulphate of galeipeine crystallizes from water in large yellow-green prisms, containing seven molecules of water and melting at about 50°; towards 100° the salt is decomposed into the sulphate of a new alkaloid and another nitrogenous substance. The presence was also recognized of a third alkaloid, which fused at 180°; it was easily decomposable and its solution showed a blue fluorescence. Neither of these alkaloids appears to agree with that described by Messrs. Oberlin and Schlagdenhauffen (*Journ. Pharm. et Chim.*, [4], xxviii., 263) under the name of "angosturine," which melted at 85° C., and had the composition $C_{10}H_{40}NO_{14}$.

Some further light has been thrown upon the constitution of quinine by the experiments of Herr Skraup, a point of contact having apparently been established between an important product of decomposition of quinine and a synthetically prepared compound (*Monatshefte*, iv., 695). Herr Skraup has found that when quinine or quinidine is oxidized by means of chromic acid carbonic anhydride is evolved and a crystalline acid is formed which he has named "quininic acid" and represented by the formula $C_{11}H_9NO_3$, differing from that of cinchoninic acid by CH_2O. When heated with concentrated hydrochloric acid quininic acid yields methyl chloride and xanthoquinic acid ($C_{10}H_7NO_3$), and this when strongly heated is further split up and gives carbonic anhydride and a phenol-like body, which has been identified with one of the three out of four possible oxychinolines that have been prepared synthetically.

The composition of the alkaloid berberine has at different times been represented by contradictory formulæ; an attempt has therefore been made by Herr Court to clear up the confusion (*Berichte*, xvi., 2589). Numerous analyses of the free base, the hydrochlorate, nitrate and sulphate have been made, the results of which point to the formula $C_{20}H_{17}NO_4+4H_2O$. With the exception of the water of crystallization this agrees with the results of Perrin and Hlasiwetz. Upon oxidation of the alkaloid in weak alkaline solution carbonic anhydride was evolved and the principal product of the decomposition was a bibasic acid resembling in composition and melting point hemipinic acid, but whether it is identical in all its characters with hemipinic acid from narcotine has not yet been determined. Herr Bernheimer has also made the observation (*Berichte*, xvi., 2685), that when berberine is distilled with a considerable excess of potassium hydrate, besides two acids that have been described by Hlasiwetz, chinoline is formed, which has been identified by its platinum salt.

Writers in German periodicals have already pointed out the defective nature of the method prescribed by the German Pharmacopœia for testing subnitrate of bismuth for arsenic. Reichardt (*Archiv*, [3], xxi., 585) shows that the nascent hydrogen produced by the action of caustic soda on iron and zinc is incapable of reducing arsenic acid; all arsenic, therefore, present in that form in the subnitrate of bismuth escapes detection when tested by the official method. In place of the latter Reichardt recommends boiling with caustic soda (test for ammonia), filtering, acidifying with sulphuric or hydrochloric acid, adding zinc and passing the gas evolved through a concentrated strongly acid solution of nitrate of silver. Experiments made by Jassay (*Archiv*, xxi., 745), however, tend to show that the bismuth salt, when boiled with caustic soda, tenaciously retains any arsenic that may be contained in it. The subnitrate is therefore best tested for arsenic by dissolving in hydrochloric acid, diluting, adding a trace of iodine and zinc; the test tube is covered with a filter-paper moistened with a concentrated *neutral* solution of nitrate of silver, upon which a trace of arseniuretted hydrogen produces a characteristic yellow spot.

Another of the tests in the Pharmacopœa Germanica said to be misleading is that for detecting storax in balsam of Peru. Grote (*Pharm. Centralhalle*, xxiv., 179) finds that genuine specimens of balsam, when shaken with petroleum benzine, yield to that liquid substances capable of producing with nitric acid the changes supposed to indicate the presence of storax. Flückiger's test, slightly modified as follows, is preferred by the author:—1 gram of the balsam is mixed with one or two drops of spirit, and to ten drops of the mixture 0·4 gram of slaked lime is added. If the balsam is pure the mass will not harden; should that take place the sample is adulterated, probably with either storax, benzoin, colophonium, copaiba or tolu.

M. G. Bruel describes a process for the volumetric estimation of iron, based upon the intense colour given by traces of a dissolved ferric salt in the presence of salicylate of sodium, and the total decoloration which takes place upon the reduction of the ferric to a ferrous salt by means of hyposulphite of sodium (*Comptes Rend.*, xcvii., 954). The solution of hyposulphite to be used is made of the strength of 1 in 1000 and then titrated with a standard solution containing 1 milligram of iron in the state of perchloride in each cubic centimetre.

During the operation of distilling some phosphorus in a current of hydrogen and condensing the vapour in cold water, Messrs. Remsen and Keiser observed the deposition upon the surface of the water of a layer of a snow-white substance, which was at first thought to be an oxide, due to some leak in the apparatus, but eventually proved to be an unusual form of the metalloid (*Chem. News*, xlviii., 201). This "white phosphorus" is light and plastic, insoluble in water, soluble in carbon bisulphide, melts at the same temperature as ordinary phosphorus and is then transformed into ordinary phosphorus. When placed upon a piece of bibulous paper so that the water is absorbed from it, it gives off dense white fumes, melts without taking fire and is converted into ordinary phosphorus. It is also at once changed into the ordinary form when placed in warm water. The authors compare this difference in physical condition to that which exists between "flowers of sulphur" and "roll sulphur." "White phosphorus" is said to be comparatively little susceptible to the action of light. One of the conditions essential to its successful preparation appears to be the presence of ice-cold water in the receiver, in close contiguity to the mouth of the delivery tube, but the operation is one requiring great care. Other substances have been described under the name of "white phosphorus," but none of these appears to be identical with the form observed by Messrs. Remsen and Keiser.

Borneol, the camphor of *Dryobalanops Camphora*, as is known, may be prepared artifically from ordinary camphor, the two methods hitherto described being that of treatment with caustic potash, and the treatment first with soda and afterwards with carbonic acid. Messrs. Jackson and Menke now describe a third method (*Amer. Chem. Journ.*, v., 270), which they say gives a better yield. It consists in dissolving the camphor in eighteen times its weight of ordinary alcohol and then adding sodium in fragments not exceeding one gram until the additions amount to one third in excess of the quantity calculated to be required for the conversion. Some of the spirit is then distilled off and water is added, upon which the crude borneol is precipitated. This when washed to free it from sodium hydrate and recrystallized from alcohol amounts to about 94 per cent. of the theoretical yield.

According to M. Jorissen (*Bull. Acad. Roy. Belg.* [3], v., 750), if linseed meal, after being stirred with warm water, be allowed to stand for some time at a temperature of 25° C., then distilled, a distillate is obtained containing hydrocyanic acid. The acid does not exist ready-formed in the seed, but it would appear that there is present in it a compound which acts upon amygdalin similarly to emulsin. A mixture of amygdalin, linseed oil and water is said to develop a distinct odour of bitter almonds.

About two years since, M. Richet published the result of some experiments upon the relative toxic action exercised by different metals on fishes. He has now supplemented these by the results of another series of experiments as to their relative action upon bacteria (*Comptes Rend.*, xcvii., 1005), the propagating liquid used being a mixture of sea water, 900 parts, neutralized urine, 100 parts, and peptone, 1 part. The metals were used in the state of chloride. The weights of the metals, in grams per litre of liquid, which sufficed to stop putrefaction are given as follows:—Mercury (Hg″), 0·0055; zinc, 0·026; cadmium, 0·040; copper, 0·062; nickel, 0·18; iron (Fe″), 0·24; barium, 3·35; lithium, 6·9; magnesium, 7·2; manganese, 7·7; ammonium, 18·7; calcium, 30·0; sodium, 43·0; and potassium, 58·0. In comparing this list with that relating to fishes (see *Pharm. Journ.*, [3], xii., 439), it appears that the proportion of metal required to prevent the development of bacteria is always larger than that which will kill fishes, and as a rule at least twenty times as much. Another point worthy of note is the innocuousness of ammonium, lithium and potassium towards microbes, and as is known towards plant life, as compared with their toxicity towards fishes and other animals. M. Richet thinks the poisons might be ranged in two classes: (1) universal poisons, of which mercury is the most perfect type, including zinc, cadmium and copper, which are poisons of the animal and vegetable cell; and (2) poisons special to animals, such as lithium, and especially potassium and ammonium, which are nearly innocuous towards vegetable tissues.

In the *Pharmaceutische Zeitung*, Herr Mader of Culmbach, reports that a parcel of this season's *Conium* herb that he examined consisted entirely of two other common umbelliferous plants, *Anthriscus sylvestris* and *Chærophyllum temulum*, without a trace of *Conium*. His suspicion was first aroused by the hay-like, not mousy, order given off when a portion was boiled with caustic soda. The substitution is easily understood on the supposition that the herb was not collected by a druggist, but by some one not familiar with botany, for the leaves of the *Anthriscus* are very similar in appearance to those of hemlock, while the *Chærophyllum* has a spotted stem. The latter, however, is easily detected even when dried by the hairiness of the leaves, and also by the swollen joints of the stem and the cylindrical fruits, if any portion of them be present, which occur in both the plants mentioned.

A species of henbane is described in the *Journal de Pharmacie* ([5], viii., 415), under the Arabic name "El Béthina," which is believed to be the plant employed by the Touaregs to get rid of the members of the Flatters mission. This kind of henbane is met with frequently a few days' journey to the south of El Golea in the Sahara region. It grows in isolated tufts and attains a height of 50 to 60 centimetres, flowering in March and fruiting in June. The plant is used by the Sahara Arabs for criminal purposes; it is known to be poisonous to the camel and horse, but is said to be eaten with impunity by the gazelle and sheep. The natives use the herb in the form of pulp or powder, which is mixed with dates or milk. The antidote used is pepper and butter, mixed with water that has been triturated with dates. This produces profuse perspiration, and the patient recovers without having experienced hallucination. The leaves of the plant are oblong, lanceolate and slightly tomentose sinuate, but not toothed, and amplexicaul at the base. The flowers are whitish, funnel-shaped, a little longer than the calyx, which has mucronate but not reflexed teeth, and is stalked. The bract which subtends the scorpioid cyme is shortly stalked, oblong, linear and entire.

The term "cellulin" has recently been given by Pringsheim (*Journ. Roy. Micr. Soc.*, p. 676) to a modification of cellulose found in the fertilizing tubes of the *Saprolegniæ*, and forming peculiar granular bodies of concentrically stratified structure, but which differs from starch in not being coloured blue with iodine and are not soluble in ammoniacal solution of oxide of copper. This new term is so near to cellulose that care must be taken by students of botany to distinguish between them.

Another new term, "haptera," has been proposed by M. Warming to include organs which serve for attaching the parts from which they spring, such as the attachment disks of the Virginian creeper, ordinary rhizomes, the adhesive tissue of *Cuscuta*, etc.

In *Schenk's Encyklopædie der Natur Wissenschaften* W. Zopf gives an exhaustive account of the *Schizomycetes*, in which he gives as his opinion that the various forms hitherto considered distinct by Cohn and others, such as the micrococcus, bacterium, and bacillus, are genetically connected. Thus the micrococcus under certain conditions may develop into the shorter rod form or bacterium, or longer rod form or bacillus, and if these divide continually may develop into the filiform leptothrix, vibrio (curved), or spirillum or spirochæte (spirally coiled) form. Any of these forms may again produce the micrococcus, which may be regarded as the final product. The production of the zooglœa or gelatinous form depends on the accumulation of resting cells and the tendency of their walls to gelatinize.

At the last meeting of the Linnean Society of London, three new British plants were exhibited, viz., *Naias marina* and *N. aloguensis* by Mr. A. Bennett, of Croydon, and a specimen of *Chara Braunii*, by Mr. H. Groves.

SCIENCE: ITS ABUSE AND USE.*

BY JOSEPH INCE.

In this age of introductory discourses, the discovery of a new subject is as difficult as the search after truth: fully conscious of the fact, and despairing to strike out into some untried path, I have chosen rather to review the past, and to lead your thoughts into a direction which may prove of service, when you, more fortunate than myself, may be on the track of original research.

Your surroundings, and the daily course of your occupations, bring you face to face with Science, not as an ideal and abstract conception, but as a living thing, clothed with power, actual as well as intellectual; and having the promise not only of the world of high imaginings, but of that prosaic world in which we have to gain our bread. There is Science, in plainer language knowledge, one and universal: the faculty of knowing and its possession. To attain this, in greater or less degree, has been the hope of all awakened human mind from our first parents down to the latest thinker. Science, thus understood, has been the theme, the teaching and the aim of all philosophy and of every system. *Scire*, is to know; *sciens*, the man who knows. *Scientia* is not the field of observation but the state. Hence it is illimitable, for it concerns the knowledge of all created things and thoughts; it is unfathomable, for the finite cannot grasp the infinite; and the span of human life

* Introductory address delivered before the School of Pharmacy Students' Association, November 15, 1883.

leaves us not the time to master that which He who is from everlasting to everlasting has ordained.

Science thus understood was a word familiar to our forefathers:—

"Ye distant spires, ye antique towers,
That crown the watery glade,
Where grateful Science still adores
Her Henry's holy shade."

Neither when the sixth Henry reigned, nor when Gray (1742) wrote his lines on Eton College, did it bear any other signification.

But the term in modern times has got a new meaning and is used in a restrictive sense. We mean by it either the knowledge of a definite group of mental observations which we label logic, mathematics or otherwise; or still oftener, though we may be tempted to resent the charge, the study of physical facts, based upon experiment, and capable of direct application.

I have no wish to criticize a definition which certainly is current; but I would ask you to note the change, else when alluding to the larger interpretation, the more limited only may be supposed.

I have to talk about a great subject in the smallest compass of words and time.

I do not wish to linger over generalities; and as all of us here are striving to cultivate science, practical or abstract, I would try to bring out specially one truth; the assumption of science constitutes its main, though not its sole abuse; but when, and just so far as science may be the synonym for knowledge, its uses are as beneficent as they are endless.

From the charge of assumption must be excepted the old world literature and its teaching.

Greek influence, and not Roman, gave the tone of thought; and the Greek drama which was the expression of the religion of the time was filled with allusions which to us are fanciful, but which in their day were accepted as articles of faith. No wonder then that their national philosophy which had no other standard should appear imaginative. The Latin authors borrowed their inspiration, and a great deal of their literature from Greece, and were less able to shake off poetic imagery and to take Nature, not the dramatists for their guide. I do not think we should blame this period for inexactness, and say that its writers were men who saw visions, and who dreamed dreams.

Sometimes they came marvellously near the truth, and especially Lucretius, as John Eliot Howard, whom we are proud to recognize as a chemist, has described. They *had* no facts, or very few; they had not enough to form a chain of reasoning. But they assumed nothing, and were not charlatans.

When their science related to modes of thought, then they redeemed their character, and gave the key to a logic which has been adopted throughout all ages. Otherwise, their science was not the synonym for knowledge, and therefore it was not beneficial to posterity.

The most wonderful thing to recollect is that for centuries, that to which we assign the name of science was latent; and we come straight down to the sixteenth century with the alchemists to find its manifestation.

There had been long talk of the art of prolonging life, and of that of transmuting the baser metals into gold. A race of men affirmed that they had hit upon the Elixir Vitæ, the Universal Solvent, the magic stone and the secret of converting one substance into another. You know the story. You must not forget that outrageous as was the system, and bombastic as were its professors, it exercised an extraordinary influence alike over the simple and the profoundly learned. Alchemy was science falsely so called; it was an abuse, for its exponents assumed a knowledge which in their own hearts they could never have persuaded themselves that they possessed. Nevertheless, out of darkness there sprang light; and we are indebted to alchemy for a recoil against all research which is based upon credulity, vanity and assumption.

A deliverance was at hand, and it was wanted. Exactly twenty years after the grave had closed over the rant of Theophrastus, rose our famous Englishman, Lord Bacon (1561). Entering at the age of thirteen the University of Cambridge, he was not seventeen years old when he wrote against the philosophy of Aristotle. This, in his opinion, was a system of definitions and of abstract speculations, which tended only to disputes. He went to Paris where he studied men and manners from the life; and at nineteen wrote his work upon the 'State of Europe.' Returning to his native land he devoted himself to the profession of the law, and was patronized by the reigning favourite, the Earl of Essex. Society bade him welcome; the court was his natural element; and his companions were the great in intellect and station. How he rose to eminence and became Lord High Chancellor; how he conceived the loftiest purposes, and stooped to actions which left his private memory a reproach; how in himself was seen the strange union between transcendant genius and the meanest practices it concerns us not here to recapitulate. We have to do with Bacon the philosopher, and find in his imperishable writings the revelation of those principles of science which for three centuries have determined the progress of the world. He touched the springs of knowledge; and you, who this day are working by direct experiment in this laboratory, are following out the lines traced by the master of original research.

The treatise, 'De Augmentis,' or the 'Advancement of Learning,' and the 'Novum Organum,' or 'New Instrument for inquiring into Truth,' created, rather say, established a new method of investigation. Many here are familiar with these things; some may not be, and for them a sketch may be acceptable which can be amplified at leisure.

Now I wish you to observe certain facts. The ancient writers on philosophy threw their strength into style and composition; their views were embodied in an incomparable diction, and their majestic sentences showed a power and glory of expression which few have equalled, none surpassed. Plato, the Greek, and Cicero, the Roman, have left passages on record which distance modern imitation. I would have you note that this was not for embellishment, but of set purpose.

Next; that whether the discourse ran on the praise of virtue or the contempt of pain; whether it was busied in recondite speculation or the quibbles of ingenious casuistry; it was unconsciously perpetuating the original temptation that they might be "as Gods," knowing good and evil.

That humanity should come as near as might be to the standard of those superior beings who lived serene in a dimly conceived blessedness was the chief aim.

Lastly, both in the contemplation of their abstract morality and of physical phenomena, they considered any leaning to the practical as of the earth earthy, and as not consistent with the dignity of a philosopher.

As there exist in man disturbing elements which war against cold theories; as in spite of all systems his humanity remains and his material interests need some provision, the grandest intellectual aspirations must end where they begin, in words.

They can issue in no real progress; and such progress was not only not aimed at, but despised. The event proved that mankind was none the better for these exalted utterances, and we may say, not in a theological and pious sense, but in the language of criticism, the world by wisdom knew not God.

When the last ancient philosopher expired he left behind him nothing but an admired essay, and in that very day his thoughts perished.

Then rose Lord Bacon, and said—"I purpose the establishment of a philosophy of such a kind as that it shall contain nothing vain or abstract, but which shall advance the condition of human life towards the better." Again: "The end of knowledge is the well-being of the human race."

Science, one and universal, must increase our happiness and ameliorate our state. Science in its separate departments must bear fruit.

At one swoop Bacon discarded idealized astronomy and mathematics; he would have nothing to do with either except so far as to discover, and accurately to describe, the laws on which they were based. There were to be no more Gods and Goddesses in the clouds. The sun ceased to be Phœbus Apollo, but was the great storehouse of heat and light. The moon had to be investigated as to her nature, motions and influence; for his lordship believed less in Diana than we do in the Man who, once on a Sabbath day, gathered sticks and became an habitual lunatic.

In short, astronomy was to be separated no longer from Natural Philosophy; and the science of the stars was to be treated in the same spirit of rational inquiry as the science of terrestrial objects.

So throughout the whole circle of knowledge: mathematics, legislation, medicine. All were to be examined upon direct evidence; and from one and all an answer was exacted to the question, How do these studies promote the well-being of mankind?

Such being the plan you will anticipate what follows. How could the designs be carried out by any other means than by observation, long and repeated; by study, actual and minute; and by experiment, persistent, consecutive and direct? How can we learn the use of anything without a knowledge of its real properties and consequent applications? This is what Lord Bacon did, and I want you, who are the heirs of his philosophy, to know why he is called the Father of Original Research.

The system which has guided all modern discovery has received the name of inductive philosophy: reasoning drawn from things repeatedly observed; by inference recognized as facts, and used systematically for the discovery of new truth. That is of truth new to us, for truth is immortal and not the creation of our researches. The skilled and the ignorant alike regulate their ideas and conduct by induction—so the burnt child dreads the fire—what has caused pain may do so again.

But while thousands trust to the light of nature, Bacon made his observations in an orderly and sequential manner: reduced them into system so as to establish laws by which other phenomena could be interpreted. He was not content that nature should casually reveal her secrets, but he sought them out, and that by the one method of experiment.

Working from the known to the unknown, he went on step by step, and learnt both by a process of separation and by direct questioning what substances were not, as well as their essential properties.

Induction in itself was no new thing—its intelligent use raised it into science.

Once say that the outward senses shall not be the sole guide; that neither mystical analogies nor poetic fancies shall be accepted in the place of facts; that these facts shall be ascertained by positive experiment in first and final proof that they are facts, and you have expressed what is meant by the inductive philosophy of Lord Bacon.

The world was ripe for the system: the hour and the man met, and how shall I sum up results? Why the complete editions of the book you read; the pursuits in which you are engaged; the daily work you do; the laboratory in which you study; the apparatus and appliances which it contains; every paper you may write; every research you make, and every success you gain; in short, your entire life and progress are the fruit of the golden seed sown three centuries ago.

I am uncomfortable when I think that my title includes the use of science, and yet I would fain have introduced a touch of the popular element into this discourse.

I take up the first good book of reference that comes to hand (their name is legion), and when I read of steam, iron and the railway; of light, heat and electricity; of the rise of all the grand commercial industries; of the splendid cultivation of the arts, and of all the beneficent adaptations which minister to the wants of man, and promote his material comfort; of medicine rescued from the hands of the pretender and marching on its double path of charity and skill; of that true chemistry (the adjective is Bacon's) which intermeddles with universal nature, and forces the barren abstract into innumerable channels of advantage; when I frequent places where wise men most do congregate and hear each man on his own special theme, speak simply, modestly, but with irresistible conviction, of things which may be the starting point of fresh discovery, or are their completion; when I reflect that there is not a single link in the chain of evidence over which its discoverer does not rejoice as part of the chain which binds us more firmly to human progress and to human happiness; I feel that I must retreat from before a subject with which I cannot cope; and I would pray you in the words of Shakespeare—

> "Still be kind,
> And eke out our performance with your mind."

Let us re-enter for a moment on the broad subject. As there is no error which has not crept into the church from a misconception of a truth; and no superstition which is not the corruption of a faith, so science itself has been liable to abuse.

I had proposed to omit altogether that palpable sort which springs from a malignant and nefarious spirit; but I must give a passing mention, lest I should be charged with excluding Hamlet from the play.

The murderer, vile and clumsy, and ignorant as he is both, selects some poisonous drug with which to destroy life. It is scarcely science which is concerned, certainly not his own, for he has but a rude knowledge that there are substances which kill; how, and why, he neither knows nor cares. This is the explanation of the vulgar choice of poisons which having marked and protracted symptoms, better skill would prudently avoid. But beyond doubt the last resources of a perverted science have been utilized when hate or lust has thirsted for revenge.

There stands Medea the classic type of villanous ingenuity; and there, Madame la Marquise de Brinvilliers, her antitype in infamy. Sensational novelists have worked up the history of this latter, but the bare facts are far more striking.

Enamoured of a handsome inmate of the household, Gaudin de Sainte-Croix, whom her own husband had introduced, a disastrous intimacy caused the lover to be hurried to the Bastille. It so chanced (I condense from an old French record) that he was confined in the same room as a Florentine called Exili, who had made himself notorious at Rome by more than one hundred and fifty poisonings. The Italian taught his willing pupil the whole art and mystery of the science; and when the chevalier got free, in turn he gave a course of instruction to his mistress. She proved a terribly apt scholar, and death (says the narrator) seemed to hover round her. All who approached her were as an untimely harvest. With gracious manner, and with a semblance of sweet piety, she carried poisoned biscuits to the hospital, and received blessings from the patients whom she was about to slay. In less than four years, from 1666 to 1670, her father, two brothers, and a sister, fell. The Marquis alone escaped; for the fear of being united to the fair fiend prompted her paramour to administer effectual antidotes as occasion needed.

Poisons became this woman's life: her element. A novice forced to take the veil at the bidding of her parents (in order to secure a fortune to the brother), told her sorrows to the Marchioness. She was compassionate, and at the end of one month, father, mother and brother were no more. The novice was free to re-enter society and the world.

Swift punishment befell the chevalier. He was distilling an active poison when the glass mask used for protection from the fumes, broke in pieces, and the poisonous exhalations did their work. He fell down dead. His papers and effects were seized, together with his receipts, and letters from the Marchioness, which she had the audacity to claim. Justice pursued her, for she was compromised beyond redemption, She fled, but by a stratagem was brought back to Paris, where not even the tortures inflicted on her, which have become historic, could wring out one syllable of confession. When all hope of pardon vanished, she wrote a full avowal of her crimes with such horrible detail that historians have refused to lend credence to its veracity. Mounting the scaffold with a firm step, she saw a crowd of the court beauties who had come to enjoy the spectacle. "Is it not a fine sight, my ladies?" said the Marchioness—and then she was guillotined and burnt.

That will do for the criminal abuse of science, and we may pass by Madame Lafarge who brought arsenic into fashion; made Orfila's reputation without saving that of Raspail; or Palmer, who rendered the word strychnine odious to his judge.

Is it not an inspiring thought, and one specially grateful to ourselves, that pharmacy, whose very name means poison, should be the grand science of detection and protection?

Let no pharmacist think lightly of his vocation. It is his to keep watch and ward whilst evil knowledge plots; his also, spoiling the spoiler, to convert the deadliest agents into healing remedies.

But lest I should too far trespass on your patience, these remarks must draw to a conclusion.

When Lavoisier was about to perish on the scaffold, he asked for a few days' time that he might complete his work in hand.

He was answered—"The Republic needs no *savants* and no chemists." Fortunately one of his earliest discoveries was that the presence or absence of an invisible body altered the physical condition of a visible solid: then this invisible gas was known as oxygen, and its nature and properties were ascertained. John Dalton, with his supreme common sense, found that each elementary body had a given weight, and that these bodies united with each other in fixed and definite proportions. From that day to this the science of chemistry has advanced, and surely I shall not be asked to sketch either its developments or its uses. With the former, even the industrious Mr. Watts with all his supplements cannot keep pace; and with the latter, you and the general public are familiar.

With what disastrous cunning chemistry has been abused, and how the secrets of the laboratory have been and are explored in order to scatter broadcast death and terror may best be learnt, unfortunately, in the columns of the daily papers.

Yet even "true" chemistry has its limits, and whenever by physical means it attempts to unravel things spiritual, the science of chemistry is abused. When a learned pundit in ponderous phrases and polysyllabic words defines life as due to the presence of aldehyd groups which are characterized by intensely active atomic movement; and death, as co-eval with and caused by, a transformation of these aldehyd groups into amyl groups, with diminished molecular motion, thus leading to cessation of action; he primarily talks nonsense; and secondly abuses science by assuming a knowledge which he does not possess.*

When a sham medical buys a bogus title, and under cover of its *prestige* tampers with the health of the community who are utterly unable to protect themselves, he but by half brings a slur upon the profession; he abuses science because he assumes a knowledge which he does not possess.

When the sham druggist opens a sham pharmacy and puts his lying bottles in the window, by which act he deceives a public incapable of discerning between the true and false; he not only degrades the calling, but he abuses science, because he assumes a knowledge which he does not possess.

When a half-educated pharmacist scrapes through an examination and is therewith content, he runs dangerously near the same indictment. Enough of shadows; let us walk in light.

The members of this Association are, of all men, least likely to be hurt by indulging now and then in speculations like the foregoing.

I have long thought that in Great Britain we keep the happy mean between abstract philosophy and the practical. Judging from the literature of the day I think we acknowledge both.

I wish from my heart that the two sides in pharmacy would make larger allowance for each other; that the quick energetic man of business would not look down on intellectual culture as so much stuff, good for the marines, and people who have time to waste; that the man trained within these walls, and successful in all his studies, would not despise the sound common sense and long experience of his less educated elder. There are two schools of education: experience in affairs and scholarship. Unite them and you have the science of trade. England is witness, by the rise of her great towns which I dare not specify lest I should offend by unintentional omission; by the lives of her great men of business; by the splendid progress of the industrial arts; that whenever abstract knowledge is made the motive power of commerce, a new and potential science is created.

Listen to Professor Huxley at the Salters' Company on Tuesday, November 13, 1883:—"The future of this country, its commercial predominance, its power of commanding the markets of the world, depends exactly upon whether its merchants or its manufacturers have or have not the wisdom to appreciate the gifts which science offers them. If they have that wisdom the command of the future is before them. If they have not, London will perish as certainly as Carthage."

Listen to Sir Joseph Hooker:—"Science is knowledge organized, and regarded in that light, nothing will be found in it conflicting with the interests of trade and social progress. Science, art and trade must walk hand in hand; if they do not, one and all must come to grief."

And shall Pharmacy, which sorely needs assistance, be kept an outcast at the gates? Shall one who makes vinegar, and another who manufactures cards tell you of the use of science? And do you mean in the nineteenth century, with all history behind you, to say, my trade is the solitary exception to the rule, and to the known law of progress?

In the name of this Association I boldly answer—No.

Yet one thought remains, the use of science to yourselves. Oh! the dreariness and the weariness of leading an objectless life; to have the wish, but not the will to work. What happier lot can be desired than having passed the rudiments of knowledge, to go on in the path of fresh discovery? That is your business here.

And if by study and by experiment you may be led from the known to the unknown into the knowledge of some hitherto concealed truth, which may advance science and be useful to mankind; not the applause of others, or some outward honour will be your first great reward; but the glow of satisfaction you will feel when your heart tells you, "I have not lived in vain."

* *Medical Press and Circular*, August 16, 1882, p. 142.

THE GELATIN BANDAGE.*

In the treatment of certain skin diseases (such as eczema, psoriasis, etc.), it has been customary to apply remedies which so obscure and cover up the affected parts that no opportunity is afforded to observe the condition of the skin after an interval of time. It is quite well known that the most commonly adopted treatment of the above class of skin diseases is that recommended by Hebra, namely, by means of tar. And there can be no doubt that the antiparasitic and antiseptic properties of tar are highly beneficial in such cases. Still, when a large portion of the skin of the body is involved, the tar treatment becomes very disagreeable and repulsive. "As one passes through the wards in Vienna (writes Dr. Rob. B. Morison, of Baltimore, in the *Medical Record*, July 28, 1883, from which we have compiled this abstract), the patients are seen lying upon beds between two blankets which, from the constant use of tar, have become so impregnated with it that the picture is anything but an agreeable one. Add to this the patient himself, covered often with a thin layer of this dirty-looking mass from head to foot, and one realizes that such treatment can only be used as a *dernier ressort*."

Recognizing these drawbacks, Dr. Pick, of Prague, has looked about for a substitute for tar, and has finally devised a treatment which, for simplicity, cleanliness, and beneficial effects, leaves nothing to be desired. [While our main object here is to describe the so-called *gelatin bandage*, the use of which will suggest itself in many cases besides the skin diseases mentioned above, we will briefly outline the other steps of treatment adopted by Professor Pick, and described by Dr. Morison.] "Instead of the troublesome use of powders and salves which in Vienna must be applied at least twice a day, the patient in Prague has immediately wrapped over his diseased parts linen bandages smeared with unguentum saponis, containing 5 to 10 per cent. of salicylic acid. This is applied in any stage of the disease, and left *in situ* for a week.

"The salicylic acid must be thoroughly well mixed with the soap ointment, whilst warm, and this must be spread, when at about the consistence of butter, evenly upon short linen bandages, which should not be more than 1½ inch in width, and even much narrower, when applied to fingers and toes. The ointment should not be in a thicker layer than the back of an ordinary table knife, and should be spread fresh every time it is used. It is not well to mix too large a quantity of the ointment, as upon standing it hardens and is more difficult of application.

"After the bandages are applied, they are covered with tricot, which is manufactured, in various sizes and at small expense, specially for Professor Pick, in England. A patient thus dressed *is able to go about his work* with no inconvenience to himself, and no injury to his clothes. After a week's time, he appears at the hospital, the bandage is removed, and the disease examined. If it is found necessary, from the still remaining inflammation and induration, a fresh bandage is applied and left on for another week. Then the gelatin is applied in the following manner:—

"*Gelatin Bandage.*

"A portion of a mass made by dissolving 50 grams of the purest gelatin in 100 grams of distilled water, and which has been allowed to cool previously, is melted by putting it in a cup, and placing the cup in hot water. To this is added the required strength of salicylic acid, usually 5 per cent. When sufficiently cool, this mixture is painted upon the diseased parts with a painter's brush made of bristles, such as is used in applying tar. The layer of gelatin is made about as thick as a sheet of writing-paper, and, after it has dried, is gently covered with a minimum quantity of glycerin spread on with the hand.

"The use of glycerin is found to be necessary to render the gelatin layer pliable, and to prevent its contracting, which it otherwise would do with considerable force; sufficient to irritate the skin. It is also worthy of note that it *is not practicable* to mix the glycerin with the gelatin before it is applied, as it prevents its hardening sufficiently, and renders it sticky. It takes a very small quantity of glycerin only, after the gelatin has dried upon the skin, to render it soft and pliable. A few trials teach the nurse the amount required. This use of glycerin obviates the only bad effect which the gelatin can possibly have. With such a gelatin bandage, a patient seldom feels the slightest itching, the diseased parts are seen through the transparent layer, thus rendering the progress of the disease visible without the removal of the application, and, what is much more agreeable to the patient, an ordinary bath removes all traces of it. So easy is this method of treatment that the patient can make his own applications in most cases.

"In making the gelatin mixture, the gelatin should be dissolved in distilled water and heated in a porcelain capsule. After stirring thoroughly, it is allowed to cool, and forms a cake which takes the form of the capsule. This cake can be kept for any length of time in paper, and the necessary quantity broken off every time it is to be used. The salicylic acid must *be kept separate* from it, and only added to the glycerin when it is melted. The mixture should not be painted upon the skin unevenly or in a thick layer. When properly applied, it can be torn from the skin in quite large pieces, and it comes off without pain to the patient or irritation to the disease. It sounds like the tearing of tissue-paper, and when thus torn off, looks as if the patient was having his epidermis removed by force.

"Any holes or rents in the gelatin covering may be repaired from time to time by a fresh application. The indications for the renewal of the whole covering are when it has worn off, or after a bath."

NOTE OF ED. N. R.—At various times, during the past eleven years, there has been a method for treating *burns* in use in the public hospitals of the city of New York which was originally devised by one of us, and which closely resembles the above-described glycerin bandage. It is known as—

"*Glue Burn Mixture.*"

White glue	troy oz. 7½.
Water	fl. oz. 16.
Glycerin	fl. oz. 1.
Carbolic acid	fl. dr. 2.

Soak the glue in the water until it is soft; then heat on a water-bath until melted; add the glycerin and carbolic acid, and continue heating until, in the intervals of stirring, a glossy, strong skin begins to form over the surface. When wanted for use, heat on a water-bath, and apply with a flat brush over the burned part.

We have been in the habit of pouring the melted mass into small delf extract jars, which were covered with paraffin-paper and tin-foil before the lid was put on, and afterwards protected by paper pasted around the edge of the lid. In this manner, the mass may be preserved indefinitely.

The materials for making the gelatin bandage may be kept on hand in the same manner. Each pot may contain a certain-weighed quantity of the mass which is stated upon a label to be attached to the pot, and which also specifies the amount of salicylic acid to be weighed out and to be mixed with the mass.

It seems to us that this glycerin bandage will form an admirable application to burns and scalds, particularly in hospitals where the mixture may be conveniently kept on hand. Its advantages over the uncleanly treatment with carron-oil and other similar applications are such that those who have tried it will always prefer to have

* From *New Remedies*, September, 1883.

recourse to it. In private practice, indeed, it is not often convenient to wait until the mixture can be procured or prepared, and for this reason it has not been much adopted outside of hospitals. But, if the gelatin bandage, as proposed by Professor Pick, should become—as it deserves to be—a regular article of commercial supply, there will be no difficulty hereafter in obtaining it at a moment's notice.

In addition to the salicylated gelatin bandage there mentioned, we may add that Professor Pick also uses a *carbolated bandage* containing up to 10 per cent. of carbolic acid. In some forms of skin disease, he employs a mixture containing either pyrogallol (pyrogallic acid), from 10 to 20 per cent., or chrysarobin. The former is transparent, and permits the examination of the skin; the latter is yellow and opaque.

Drs. Unna and Beiersdorff have lately experimented on the applicability of this method to other remedies, and have found that the proportion of gelatin, water and active ingredient must be changed according to the nature of the latter. They have established three series of masses, containing respectively, 5, 10 and 20 per cent. of gelatin, which they have classified in tables, in each of which the respective remedies are enumerated (see *Monatsh. f. prakt. Dermat.*, 1883, No. 2). Table *A* contains jellies with 5 per cent. of gelatin, of a consistence of a gelatin-bougie; they are easily melted by being immersed in hot water, and after being applied to the skin, rapidly solidify. They are called *Gelatinæ glycerinatæ molles.* Table *B* contains the *Gelatinæ glycerinatæ duræ*, with 10 per cent. of gelatin. In the case of these, it suffices to pour a few drops of hot water upon the surface, and to rapidly apply the solution thus produced, which sets quickly. Table *C* enumerates the jellies with 20 per cent. of gelatin; these are made without water. Among these are the jellies of pyrogallic acid and tannin, because any addition of water in these cases would cause chemical changes. The authors also found that fatty substances, up to 30 per cent., even with addition of water, can be incorporated in the mass, provided it consists only of gelatin and glycerin. In the case of chrysarobin, the authors likewise recommend the omission of water, and to make it so as to contain 5 per cent. of gelatin, 5 or 10 per cent. of chrysarobin, and 90 or 85 per cent. of glycerin.

NAPHTHOL: ITS MEDICINAL USES AND VALUE.*

In a paper under this title, read before the Philadelphia County Medical Society on the 17th ult., by Dr. John V. Shoemaker, Physician to the Philadelphia Hospital for Skin Diseases, that distinguished dermatologist calls attention to naphthol in a manner calculated to ensure for that drug a more extensive trial by the profession of the United States, than has yet been accorded it.†

Naphthol is a derivation of naphthalene, a hydrocarbon found in large quantities in coal tar, belonging to the so-called aromatic group. It bears the same relation to naphthaline that phenol does to benzol, and cresol to toluol. It was first employed by Professor Kaposi as a substitute for tar in skin diseases, being considered by him as the essential curative ingredient of that substance, while being free from its objectionable features. The preparation employed in the cases which form the basis of Dr. Shoemaker's report was that made after the method of Dr. Justus Wolf, being free from odour and coming in beautiful crystalline scales. This preparation decomposes under the influence of heat when it again becomes odorous and pungent. The commercial naphthol contains impurities which unfit it for use in medicine. Naphthol thus properly purified is an extremely powerful antiseptic and disinfectant. One part added to 480 of urine kept the latter from decomposing for six months, while another sample of the same urine to which naphthol was not added had a strong putrid odour at the end of eight days. The addition of the naphthol to this putrid sample divested it of all odour within twenty-eight hours.

Dr. Shoemaker's therapeutic experiments extended through some nine months and sufficed to convince him of the great value of naphthol in medicine.

He found it to fully sustain the claim that Kaposi had made for it in scabies, psoriasis and chromophytosis, as well as in some of the chronic forms of eczema, in which it not only allayed the itching attendant thereon, but lessened the infiltration as well. In wounds and indolent ulcers it is a most useful detergent and deodorant, removing the fetor and establishing healthy action of the parts. Aqueous solutions, containing half grain to the ounce, were used to great advantage as vaginal injections, especically in leucorrhœa and uterine carcinoma, as well as in gonorrhœal affections, both in male and female. In diphtheritic throat affections it made a most useful gargle, as well as to remove the fetor of catarrhal and other affections of the buccal cavity. Its greatest value, however, arose from its disinfectant action on the evacuations of fever patients and in rooms containing them, while by its absence of odour it did not tend to produce inconvenience either to patient or attendants. Combined with powdered talcum or starch, or both, and dusted into the shoes or stockings of those affected with fetid exhalations of the feet it acts most satisfactorily, and its effects are equally as good in the same affection involving the hands, axillary and inguinal regions. Combined with other ointments in the proportion of from one to ten grains to the ounce, it not alone preserves the unguent from decomposition, but exercises also an antiseptic action on the parts and the exudation therefrom. A slight admixture to an experimental sample of lard preserved the same in excellent condition throughout the hot summer months. In chronic psoriasis, particularly when there is great infiltration, a five to fifteen per cent. ointment was frequently attended with good results. It also proved very effective in squamous and fissured eczema, used in combination with lard or gelatine.

After his long and successful employment of naphthol Dr. Shoemaker was surprised to find that serious untoward effects had been reported from its use by foreign authors. With a view to further testing its toxic properties he first administered to a rabbit internally in a saturated solution. But on discovering no injurious effect he selected another rabbit which he determined to poison with a view to observing the *post-mortem* appearances. He accordingly gave it at first one-grain pills of naphthol every three hours, and subsequently increased the amount to two grains and again to four grains at the same intervals. But beyond increasing the animal's appetite no effects were apparent. Following these experiments two of his assistants took numerous and large doses (reaching as high as five grains twice a day) without other effect than a sensation of temporary warmth in the epigastric region after each dose and subsequent slight vertigo and buzzing of the ears, with other evidences of hyperæmia. The alvine evacuations were softened to a mushy consistence and changed to a clay colour; in one instance diarrhœa occurred. The deduction from these experiments clearly is that in the case of the ill effects reported an impure preparation had been employed.

Dr. Shoemaker pronounces purified naphthol to be far superior to carbolic acid and the other antiseptics which have been in vogue, while it is almost absolutely odourless. It has the advantage also of being cheaper than carbolic acid, when the amount required to produce its effect is considered.

JOHN ELIOT HOWARD, F.R.S.

OUR obituary column this week contains an announcement that will be read with regret in every quarter of the globe: JOHN ELIOT HOWARD, the eminent quinologist, has suddenly and unexpectedly passed away. In every land where the acclimatization of cinchona plants has been attempted and in every community interested in securing a constant supply at a moderate price of the valuable alkaloids derived from them—and what community is not?—it will be felt that the world has lost one of the men who have laboured most arduously and successfully towards the attainment of these ends. The subject of the cinchonas, with which Mr. HOWARD's name will no doubt be long and honourably associated, was taken up by him at a time when, although attention had been called to the increasingly rapid extirpation of the plants in the districts from which bark was then obtained, nothing had yet been done to avoid the extinction of the genus in its native habitat or to transport it to a new home. His first paper was published in 1852, and was very characteristic of much of the work done by him; it consisted of a lengthy report on the results of a laborious and painstaking examination of a series of Peruvian barks in the British Museum, which had been collected by the Spanish botanist PAVON. Whilst engaged in this investigation, in which he had the counsel and assistance of Dr. PEREIRA, Mr. HOWARD was led to suspect the existence of other results of the labours of Spanish botanists who had studied this subject, and as a result of inquiries made in Madrid he succeeded in obtaining more specimens of barks, and, what was of still greater value, the manuscript of an unpublished treatise by PAVON. This manuscript was carefully edited by Mr. HOWARD; Mr. FITCH was dispatched to Madrid to make drawings of the specimens in the national herbarium; and after a lavish expenditure of time, care and money the outcome was the appearance of the magnificent volume know as the 'Illustrations of the Nueva Quinologia of PAVON.'

But before the publication of this fine work, Mr. CLEMENTS MARKHAM had succeeded in introducing live cinchona plants into India, and a new field was thus opened up into which Mr. HOWARD went to work *con amore.* Unceasingly he corresponded with collectors and cultivators; hundreds of specimens of bark from the Madras and Bengal plantations were analysed; plants were reared in his own greenhouses to assist in clearing up doubtful points as to doubtful origin: and the results of all these labours were at once and freely placed at the disposal of the public. The Indian Government, recognizing the value of his unique experience, consulted him on numerous occasions, and profited by a series of admirable reports from his pen. The services thus rendered to the State by Mr. HOWARD in connection with this subject have always been warmly acknowledged, and on one occasion the special thanks of the Government were conveyed to him by the Secretary of State; but we are inclined to think that they might have been more suitably rewarded by a more evident mark of honour. Mr. HOWARD'S counsels with respect to the species of cinchona that should be cultivated were consistent and farsighted, though not always palatable. During the infancy of the acclimatization experiment fresh and extensive sources of bark had been opened up in South America, and Mr. HOWARD recognized and urged that the only prospect of a commercially profitable investment of capital in cinchona planting would be associated with the raising of plants yielding bark rich in quinine rather than others that might be of more robust growth but yielding barks in which the inferior alkaloids preponderated. With a view of rendering the fruits of his experience as widely available as possible Mr. HOWARD issued in 1869 and 1876 the three parts of his 'Quinology of the East Indian Plantations,' which has its only rival in the author's previous work.

The labours of JOHN ELIOT HOWARD are over, but the harvest is far from being yet reaped. Many a poor sufferer who never heard his name will profit unconsciously from the work of his life, and the wreath of cinchona leaves laid on his coffin was a fitting emblem of the service he has rendered to humanity. Only a few weeks before his death he received in the Hanbury Medal a testimony from those best qualified to judge his work as to his "high excellence in the prosecution or promotion of original research in the natural history and chemisty of drugs," and the honour will seldom be awarded to one more worthy to receive it..

BOTANICAL NOMENCLATURE.

ALTHOUGH, under the influence of the new school of physiologists, botany is rapidly losing its reproach of being a mere science of classification, its system of nomenclature is perhaps the most perfect of any of the natural sciences. This is mainly due to the fact that several of the most illustrious botanists of recent times,—among whom must especially be mentioned two still living, ALPH. DE CANDOLLE, of Geneva, and our own veteran, Mr. BENTHAM,—have applied their great powers especially to the perfecting of the laws of nomenclature. The system now all but universally adopted was formulated in a canon of sixty-eight articles laid down by a Congress held for the purpose at Geneva in 1867, which originated mainly with M. De Candolle. The experience of the sixteen years which have elapsed since then has suggested some slight modifications or extensions of these articles, which are published in a *brochure* by the same authority, entitled 'Nouvelles Remarques sur la Nomenclature Botanique' (Genève, 1883). An additional article extends the laws of nomenclature contained in the remaining articles to all classes of the vegetable kingdom, and to fossil as well as to living plants; and in another the term "*mutation*" is applied to a form occurring in a later geological period, but which is still regarded as belonging to the same species as one previously described. Another new article lays down more emphatically than before the principle that a generic name once given must not be altered in order to make it more correct from a linguistic, euphonic, or even from a descriptive point of view. It is obvious that, if it is once admitted that a name once given may be changed in accordance with the caprice, or even with the superior learning, of a subsequent writer, the uncertainty and confusion introduced into nomenclature would be endless. Another new article insists that "the designation of "a group has not for its object the enumeration of the "characters or the history of the group, but simply "the supplying a means of recognizing it when spoken "of." There can be no doubt about the soundness of this view, and it may well be applied to specific names, as well as to those of larger groups. To attempt to describe a new species in its name is usually a mistake; a larger acquaintance with the species and with its allies frequently making such a designation to a certain extent a misnomer. Thus, among familiar English plants, *Epilobium montanum* is our commonest lowland willow-herb, "ascending," according to Hooker, only "to 1700 feet;" and *Bromus maximus* is, by the same authority, in all respects a smaller plant than *B. sterilis*. Still, to alter these names, when once given, would be opposed to all sound rules of nomenclature. Indeed, as a general rule, the more arbitrary the name given to a new plant the better. M. De Candolle draws an interesting comparison in this respect between the gradual change in the style of nomenclature of men and of plants. Nations in a rudimentary state of civilization give names which describe some personal peculiarity or habit of the person named. In a more advanced state of civilization a name is merely a ticket by which a man or woman is known, and something also of his descent is indicated. Before the time of Linnæus the name of a species was at the same time an enumeration of its characters. The objectionable features of descriptive names are more clearly seen when they are translated into English. Nothing can be more absurd than the practice of some botanical writers, of translating the Latin name of every plant, and calling this the English name of the plant. In one small point the current style of nomenclature of plants and of animals differs. In botany the accepted rule is to write all specific names with a small initial letter, except when they are derived from the name of a person; thus:—*Hieracium Lawsoni*, but *Hieracium anglicum*. In zoology the specific name is written with a small initial letter, even when it is the genitive case of a person's name, as *Phasianus reevesi*. In this respect we cannot but think the rule adopted by botanists is the preferable one.

On Wednesday next, December 5th, the usual Evening Meeting of the Pharmaceutical Society will be held. Messrs. Dunstan and Short will present a continuation of their "Report on the Pharmaceutical Preparations of Nux Vomica," dealing on this occasion with the Tincture and the Extract. There will also be a paper on "Tincture of Cinchona," by Mr. E. G. Hogg, and two communications upon the Purgative Principle and the Vesicating Principle of Croton Oil, from Mr. Harold Senier. The chair will be taken at 8.30, but the Theatre will be open an hour previously, to afford facilities for the inspection of recent donations to the Museum and other articles that may be shown.

*   *   *

We regret to have to report that information has been received of the death, on Sunday last, of another of the "approved candidates" for annuities from the Benevolent Fund, Mr. Hugh Talbot, whose name was sixth on the list published last week. This name also will therefore be obliterated from the voting paper, in order to prevent votes being wasted.

*   *   *

Considerable confusion appears to exist in the published communications upon the subject of "kairin," as to the exact application of that name. In some papers having the appearance of being authoritative,—as for instance one by Professor Filehne (before, p. 383),—that substance has been described as oxychinolinmethyl-hydride, and the "hydrochlorate of kairin" has been spoken of as a distinct compound. In the paper, however, in which Dr. O. Fischer described the preparation of this and other allied compounds to the Berlin Chemical Society (*Berichte*, xvi., 712), he uses the term "kairin" as a synonym of "oxyhydromethylchinolin hydrochlorate." But by the courtesy of a correspondent we have had an opportunity of reading a letter in which it is stated, on the authority of the manufacturers, that the substance at present supplied by them under the name of "kairin" is the "hydrochlorate of oxychinolin ethyl." Possibly this compound is identical with the "α-æthoxychinolin hydrochlorate," which Dr. Fischer distinguishes as "kairin A." In view of this confusion we purpose publishing an abstract of Dr. Fischer's paper on an early opportunity.

*   *   *

Notwithstanding the disadvantages under which sulphate of cinchonidine was placed for a time in the United States, as compared with sulphate of quinine, through the ambiguity in the Tariff Act, to which we recently referred, it appears to be coming largely into use in that country. According to Messrs. Gehe all that can be obtained in the German market is bought up and sent across the Atlantic.

* * *

According to a Parliamentary return issued during the present week, the gross amount of revenue received during the year ending March 31, 1883, on account of patent medicines was £157,773 17*s.* 1½*d.*, which represented the duty paid on 18,457,990 packets.

* * *

In a recent consular report it is stated by Mr. Consul Wrench that the grower of opium in Turkey does not cover his expenses when the price of the drug in Constantinople falls below twelve shillings per pound; but that unless prices fall to and remain permanently at this low figure there is a probability that opium cultivation will increase in that country. The produce for the year 1882 was small, about 4500 chests, but the prospects for the present year were considered to be very good, and have already affected the price.

* * *

The President of the Pharmaceutical Society (M. Carteighe, Esq.) and Dr. B. H. Paul have been elected Honorary Members of the Danish Pharmaceutical Society.

* * *

Mr. Joseph Rees, Chemist and Druggist, has been elected Mayor of the town and borough of Cardigan, and Mr. Daniel Woolley, Pharmaceutical Chemist and Vice-President of the Stockport Chemists' Association, has been elected an Alderman of the borough of Stockport.

* * *

The next meeting of the Chemical Society will be held on Thursday, December 6, when there will be a ballot for the election of Fellows, and the following papers will be read:—"On the Constitution of the Fulminates, and on Liebig's Production of Fulminating Silver without the use of Nitric Acid," by Messrs. Divers and Kawakite; "Note on the Constitution of the Fulminates," by Dr. H. E. Armstrong, and "Experimental Investigations on the Value of Iron Sulphate as a Manure for Certain Crops," by Mr. A. B. Griffiths.

* * *

A meeting of the London Section of the Society of Chemical Industry will be held at Burlington House on Monday evening next, when papers will be read entitled "A New Residual Product from Coal Gas," by Mr. H. L. Greville, and "Further Notes on the Stassfurt Industry," by Mr. C. N. Hake; and Mr. A. Zimmerman will exhibit Rayat and Kunheim's Liquid Carbonic Acid Apparatus.

* * *

A special general meeting of the School of Pharmacy Students' Association will be held on Tuesday next, December 4, at 8.30 p.m., to consider a revision of the rules.

* * *

We are requested to state that the next meeting of the Chemists' Assistants' Association has been postponed from Tuesday, December 4, to Thursday, December 6, when a paper on "Digestion" will be read by R. Wharry, Esq., M.D.

Provincial Transactions.

SHEFFIELD PHARMACEUTICAL AND CHEMICAL SOCIETY.

A general meeting was held in the Society's rooms, Market Place, Sheffield, on Wednesday evening, Nov. 14. Mr. Preston, the President, in the chair.

The minutes of the last meeting having been read and confirmed, the Secretary announced that the following donations had been received:—The *Pharmaceutical Journal* from the Pharmaceutical Society; one guinea from Mr. J. F. Wilkinson, Manchester.

Votes of thanks having been passed to the donors, the President called upon Mr. E. R. Learoyd to read his paper on—

Apprentice and Student.

Before even the Pharmaceutical Society became possessed of the Royal Charter, at a meeting of the youthful Association which was eventually to merge into such an important body, held on May 11, 1841, the honoured founder, Jacob Bell, made use of this statement,—"When we consider the advancement of art and science generally in this country, it is a matter of surprise and regret that pharmacy and pharmaceutical chemistry do not receive that scientific support which is conceded to them in other nations in Europe, and in America." Further, he said, "In chemistry and philosophy, in medicine and surgery, Great Britain holds a prominent plrce; in arts and manufactures we can compete with the whole world; but in pharmaceutical chemistry, in the application of the science of chemistry to the art of relieving the numerous maladies to which human nature is liable, it must be admitted we are deficient."

I have thought well to commence these few remarks with the words of one who has long passed away, but whose name will be reverenced by the pharmacist as long as such exist, in order that not merely might it serve as the introduction to my paper but would forcibly illustrate two principles which I think you will agree with me are admitted thereby: one is that at and prior to the year 1841 (now more than a generation ago) the chemist held an unimportant and rather ignominious position in the estimation of those classes of society who were supposed to be best able to judge of his merits or estimate his worth. The second conclusion we are bound to acknowledge is, that while other sciences, with their several applications, had been making great strides, pharmacy, in the words of the eminent authority I have just quoted, proved admittedly deficient. Deficient in what? In social position? Surely any one who is at all acquainted with the high premiums paid for boys to become apprenticed to chemists of those days must allow that no question of this kind can carry very great weight. In education? Well, then, again I infer that the parents or friends of such youths would be in a position to give them a more than decent education, generally speaking, for the position in life for which they were eventually to qualify. Then in what do we find they were deficient? Again I must refer to the clear and distinct reasoning of Mr. Bell, for I am at a loss to describe, in better terms than his own, the wherefore, which he gives as follows:—"This deficiency may be attributed to the absence of any specific and distinct course of education in this particular department, to the want of a sufficient stimulus to exertion in its advancement, and to the consequent neglect which degrades it below its proper standard of importance." These are strong terms, and may now by some be considered to seriously reflect on the chemist of the past. However, to-night it is our pleasure to be interested somewhat in the apprentice, the youth who is by nothing more than the mere effluxion of time to become the representative, worthy or otherwise, of those whose teachings he has imbibed and in whose footsteps he may be considered hereafter to tread.

Then the question at once arises, to whom were these youths indebted for the knowledge which should fit them for the onerous and important duties they were soon to be called on to fulfil? I can quite imagine that in putting a lad apprentice even then, his friends took very carefully into consideration the fact that a commensurate remuneration must be probable for the outlay in premium and in time expended in acquiring the information necessary to a successful career. But what were the "principals?" Were they able properly to teach or give opportunities to be taught that which of necessity can only fit the aspirant for the position to which he looks forward? To quote once more, Mr. Bell says:—"The chemists and druggists of England have been called into existence by the public demand for a class of persons who devote their principal or exclusive application to the art and science of pharmacy."

But here I am bound to take exception; it seems to me somewhat grandiose and presumptive to assume that such be the condition of affairs, while in the same breath almost we have been told that the chemist was, alas! in the most eminent degree deficient.

It seems strange, but at the same time excusable, that our author, having so earnestly the interests of his fellow-chemists at heart, should at times be rather illogical; but a pang of remorse must have filtered into his breast when he adds, that "In the absence of a uniform system of education it cannot be expected that all 'dispensing chemists' can be equally competent." "Though," he adds, recurring again to his former position, "we must admit that among some of their number a reformation is much required."

It is quite safe to say that at the time the paper just referred to was written, not only did chemists and druggists exist, but they were without doubt called on continually to execute those professional duties apart from mere commerce, which to-day they are expected to be qualified to undertake; in fact Mr. Bell admits that such were in existence and active occupation, for we are told how "pharmaceutical chemistry comprises several departments, the manufacturing chemist, the analytical chemist, the dispensing chemist, how they carry on their respective functions, and finally how from division of labour manifest advantage results.

Thus we see again that the chemist was not only in existence, but it is, I think, fair to presume, was to some considerable extent enjoying the confidence, if not of the scientist, at least of the general public, to whose daily requirements he was devoting his experience and his life.

We must not forget that at the time Mr. Bell made use of these statements he was, as it were, really paving the way for the emancipation of the trade, by the inauguration of the great scheme of education to which he had become so devoted. At the same time, it answers our purpose to-night to consider carefully the arguments used. Why, I will shortly endeavour to explain.

In further announcing the objects of the infant Pharmaceutical Society, Mr. Bell says:—"But some course of education is necessary to qualify all these classes of 'pharmaceutists,' and in the absence of any national institution of this description the attainment of that proficiency from which public benefit can be expected is due to the voluntary and unassisted assiduity of individuals, and not to the system under which they are placed."

Thus we at once see that all this goes to prove the desirability of a national course of education.

But the question now arises, Under what conditions and in what position were the apprentices of the past? Speaking pretty generally I suppose we may consider the apprentice of a generation ago to be much in the position of the apprentice of to-day, with one or two important exceptions. In those days most people in business took (as it is termed) apprentices, and it speaks volumes for the probable pecuniary value of such business that they were able to command good, and in many cases what we should now consider high premiums. To-day it is different, and the tendency of the times is to do away altogether with apprenticeship. Then the youth, whoever and whatever he might be, had to go in as at first little better than the errand boy—begin at the beginning, work hard and long, and only after some years' difficult and laborious servitude would he be able to advance his position in the shop. Times and habits were different. Our forefathers worked longer hours than now universally prevail, and we can well imagine the unfortunate boy, his mother's darling, his father's pride and hope, writing home laboured and affecting accounts of his hardships and troubles as a chemist's apprentice.

That such was the case and that hardship was felt we are quite convinced, for having only again to refer to an article by the Editor of the *Pharmaceutical Journal*, written in or about September of the same year, 1841, which at once shows us how the shoe pinched. In it we are told how a variety of letters have been received from assistants, describing the hardships and disadvantages under which they laboured; and the writer goes on to say that the position of an apprentice or assistant in a chemist's shop is attended with much labour and many privations, close confinement, long hours, constant and wearying application of the faculties to duties which possess in themselves but little interest, the necessity for study and the difficulty of finding time or energy to devote to it; in addition, the labours of the counter.

The usual complaints appear to have had reference to late hours, confinement to business during *seven* days of the week, the want of time for recreation or amusement, and in, some cases, defective domestic arrangements.

So then from an eminent authority do we gain the information that the apprentice of the past was, if not a particularly worthy, at any rate, a much to be commiserated creature. In country towns, and in the majority of cases in the principal cities, the years spent in apprenticeship were usually years of incessant toil.

Apprenticeship for much longer periods prevailed than is now the custom. Used in many cases as cheap labour, we may suppose mental improvement to have been often carelessly neglected and habits of thought considered, if indeed consideration entered at all into the matter, to be subservient to mere handicraft. In our own time we can unfortunately find instances of this. I, myself, have had an assistant who confessed that during the whole of his apprenticeship, he had never made up, or dispensed if you like, what he called a "proper prescription;" to whom the obvious inference must apply I leave to you, as also I leave to you to determine what sort and condition of man would, by such training, be launched upon the troubled sea on which rocks the chemist's "bark."

A good deal might be said as to peculiarities exhibited by some masters. To mention my own case again, I have in the "West-End" of London served as assistant to a pharmaceutical chemist who only allowed the use of the Pharmacopœia to his young men, giving them to understand that his establishment was not to be considered a training school for pupilage but a place for *work*, that is, *his work*. Such narrow-mindedness is beneath contempt and assuredly brings its own reward.

Then, again, situations with their differences in locality and class, differ accordingly in routine. Whilst the youth in London would be complaining that business spreads over such an extended day that owing to circumstances half a day's work remains to be accomplished after eight o'clock at night; on the other hand, the country apprentice was so completely exhausted with pounding, weighing and mixing, that, taken into consideration with the little encouragement received, it was no wonder that "wearied nature sank to rest," or sought relief in perhaps somewhat doubtful recreation.

One point for congratulation may at least be discerned amid the dreariness of this rather dismal category, one redeeming feature, one happy example which serves at least to lighten the general gloom, and this we find by remembering that it has been conceded that advancement even in those times was not impossible, the ladder of progress was not altogether thrown down, and to those who perhaps a little favoured by exceptional circumstances, or by indomitable industry, it was, we are thankful to say still possible to achieve something like success. It has just been admitted that the attainment of proficiency was due mainly to the voluntary and unassisted assiduity of individuals, and all honour to those whose responsibility was so acknowledged, whose trust was not betrayed, and whose interest in the future welfare of their juniors led them (in the exercise of an anxiety sensible to the requirements of the times) to stimulate by the best means at their disposal those habits of study and general conduct, which, properly fostered, bring forth the happiest results.

And well it is for us to look back and note the names of but a few of those pioneers who have, pharmaceutically speaking, "cleared the way,"—Bell, Payne, Pereira, Christison, Liebig, Thompson, Ure, Morson, Redwood, Savory, Deane, Squire, Clarke, Ince, Hanbury and many others,—and I ask you to decide whether or not these names are worthy of your regard, or are not those you would delight to honour.

But for all that, speaking generally, this I take it was the state of affairs in the past: youths put to a business, entailing serious and responsible duties; left very much to their own resources; enjoying, if one may call it such, a somewhat lengthened period of servitude; but unfortunate in having no stated course or educational programme which might prove an incentive to effort, or serve as a guide in directing their studies.

Years have passed away. The plea that the interests of the chemists as well as the safety of the public demand that no person shall become an apprentice in the business who has not had the advantage of a fundamental education, and that no person shall dispense medicines who has not undergone an examination as a test of his competence to perform that important office, has become, as far as the legal definition is concerned, an accomplished fact.

The generation which worked so arduously and disinterestedly for this end has all but passed away, and it becomes an interesting question as to the position the chemist now holds. Has the work prospered? Does the position of the chemist to-day realize the desires and prognostications of the founders of the Society? And more particularly, after all these years of progressive development, is the position of the chemist's apprentice or the "student of pharmacy," as I may now venture to call him (for I am informed on very eminent authority that the days of apprenticeship *as such* are numbered), one which is a matter to us for congratulation or regret?

I am happy to think that I can answer the latter interrogation in the affirmative, and that it does not take any very lengthy consideration to determine that the status of the young man who now aspires to enter the ranks of pharmacy is infinitely superior in nearly every respect to that enjoyed by his predecessor of a generation ago.

To my mind, however, there is something of sadness and regret, as there is something to be admired, in these reminiscences of by-gone days, when men lived and worked much as we are living and working now; when almost alone and often unaided industry and pluck lifted, as it were, a man above his fellows, and when, in spite of difficulties and discouragement, there arose those whose names we mention with respect and esteem.

Undoubtedly *we* should not forget the lessons which the history of the past teaches, some of which I trust you will be able to gather from these remarks.

But "has the work prospered?" Well! to-day we have the Pharmacy Act an accomplished fact; we have the sale of poisons in the hands of only qualified chemists; we have the dispensing of prescriptions more or less efficiently conserved and protected; we have the "title" clearly described and surrounded by the necessary bulwarks; we have pharmacists occupying responsible and honourable positions as analysts, and in other important official capacities; and finally, we have, *or think we have*, an increased status in the estimation of the public at large. With all these advantages, does the position of the chemist to-day accomplish our desires, is our satisfaction reasonably complete? To this question I am compelled to answer, reluctantly but decidedly, No.

That the chemist has all this we admit, and in the abstract privileges such as are most admirable we also admit; but that any real advantage commensurate with the enormous outlay of years of anxious effort has yet dawned on the chemist and druggist, as a whole, we are prepared to doubt. That his anxieties are lessened; that his status is materially improved; that his work is lightened (except in the sense of division of labour); that his hours of business are sensibly relaxed; that his time for relaxation is increased; that his pecuniary emoluments are enhanced; and, to sum up, that he is prominently benefited in the practical sense, rather than in mere theory, again I venture to say you will with me very much doubt.

Nevertheless, there will be those who will tell you that, in the increased knowledge which the chemist has at his command, in the increased interest which things, once common to him as household words, assume by enlarged intelligence, and in the increased power which general enlightenment has given him, there will be found a fund of interest and gratification far beyond any ordinary and common satisfaction; which may be pointed to as the highest aspiration of what might be designated the mere "trader of the past."

Again, may I be permitted to say that once more you will be inclined to accept this argument *cum grano salis.*

But it is with a sense of relief that we turn to our friend the "student" of to-day. He, without doubt, is in the enjoyment of advantages far beyond the wildest dreams of the average youth of the year 1841. Certainly we have to deplore the continuance of late hours,—and whilst we are reminded on this subject, once for all we would lay down the rule, that those who most transgress by keeping open their places of business unreasonably are, with but few exceptions, the new beginners, those who as assistants were the readiest grumblers. Still the Pharmacy Act, if it has done nothing else, has at least done this,—it has given the student a *locus standi*; it has provided for him a curriculum; it has opened to him schools with eminent teachers; it has provided the necessary *stimuli* in the form of exhibitions, scholarships and medals; and finally, after a fairly studious career, enables him to boast of its laurels being placed upon his brow in the shape of the highest degrees at its command.

That the Pharmacy Act is perfect I for one am not at all prepared to admit, and one (to me) great evil, a blemish difficult to understand, if we take into account the amount of consideration the Act involved and received in its preparation, is that young men are only required to serve, or rather be in the occupation of, a duly registered pharmacist for the short term only of three years. I fear much of the disappointment felt by young men entering into business springs from this source.

If nothing else, we may safely look on the old-fashioned plan of five, six or seven years' apprenticeships as one by which the young man would be retained under the immediate superintendence of his master for a period sufficiently long to do two things, viz., to "mould his character," and to give him necessary experience as a business man.

Not in mere boyhood was he to be considered as an "experienced dispenser" (for that I take it, the law being complied with, is the case now), not with habits sufficiently disturbed to give him a distaste for a business, the most unpleasant part of which in the natural order of things comes first, not before he had been sufficiently long with his principal to properly grapple with that important problem of supply and demand which we must all study, and not before, under his master's own eye, had he had sufficient time to develop, if in him was, those traits of character which should send him into the world at once a credit to his trainer and himself.

Perhaps it might be interesting to notice one instance of how the ideas of the Utopians (if we may be so permitted to call them) of the past, permeated through the pharmaceutical world and whether any result was produced.

In 1841, Jacob Bell had promulgated his ideas, and as far as I can learn by the records of the Journal, it was only in 1843 that the first official notice appears of any effect, educationally speaking, having been produced in the country. In January of that year (1843), however, a course of lectures, the first which I can find to be officially recognized, takes place in Manchester, and the circumstances are worthy of record from the singular fact that it is evident that wide-spread interest is exhibited in the new departure; for instance, on this important occasion, forty-four tickets were sold, forty-three to members and associates were 10*s.* 6*d.* each, and one non-member was charged as much as 1 guinea (21*s.*). The lectures took place in the Theatre of the Manchester Medical School, and were delivered by a Mr. Davies.

Of those who attended, four were from Rochdale, eleven miles away; two from Oldham, eight miles; three from Stockport, six miles; one from Hyde, eight miles; one from Bury, nine miles; and one from Bolton, twelve miles; thirty-two being from Manchester, Salford and the neighbourhood. How long the Local Society went on, though assisted by a grant of £30 from London, before being seized by that inevitable consumption which has destroyed so many Provincial Associations, I am not in a position to say. . . . .

The author concluded by saying that in these days we are proud to think there is a brighter look out and a better prospect for the future. Compulsory education was considered necessary and it has been brought about. Means for obtaining the required knowledge could not be dispensed with, therefore such have been satisfactorily arranged for; and it is only fair to assume that in the near future in other places, as in Sheffield, when the requirements become obvious, there will spring up as occasion demands, those opportunities which, if sufficiently embraced, fit our students to take a respected and worthy position in the business they have chosen and in society at large.

The President, invited discussion on the paper, said that the subjects touched upon by Mr. Learoyd were of very great interest, and that the members could not but feel obliged to him for the very able and lucid way in which he had brought the matter forward.

Mr W. Ward was pleased to accord his hearty thanks to Mr. Learoyd for his paper, and to see that the subject had been so attractive to the rising generation as evidenced by the large attendance of associates; he took it as a good sign of the future of pharmacy. He did not agree with those who say education unfits a man for business; he considered that the more highly a man was educated the more likely would he be to succeed, especially when his knowledge is combined with practical common sense; higher education had always been the aim of the Pharmaceutical Society. He had very great pleasure in proposing a vote of thanks to Mr. Learoyd.

Mr. Ellinor seconded the vote of thanks, saying that the apprenticeship of to-day was very different to what it was when he was an apprentice; students had now every opportunity of learning, and it was their own fault in a great measure if they did not get on.

Several other gentlemen joined in the discussion, to the various points of which Mr. Learoyd replied.

The vote of thanks was carried heartily.

Before the conclusion of the meeting, Mr. W. A. Shaw was elected an Associate of the Society.

EDINBURGH CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

The third meeting of the sixth session was held in the rooms of the North British Branch of the Pharmaceutical Society, 119A, George Street, on Wednesday, November 21, at 9.15 p.m. Mr. Claude F. Henry, President, in the chair.

There was a large attendance of members and others.

The minutes of last meeting having been read and confirmed, Mr. Peter MacEwan proceeded to read a paper on "Volumetric Analyses."

After some introductory remarks, in which the author urged the importance of everyone connected with pharmacy being able to verify the strength of the medicines before supplying them to the public, he stated that volumetric analysis was one of the most efficient means towards this end, and proceeded to show in what it differed from gravimetric analysis. He then briefly sketched the history of the process as follows:—

"In 1806 Descroizelles, a French chemist, published an account of a new method which he had devised for ascertaining the alkali strength of barilla and potashes. His method consisted in the employment of a 10 per cent. solution of sulphuric acid, which he poured from a graduated tube into a solution of a known weight of the sample until the mixture became slightly acid. The standards which he chose were entirely arbitrary, and consequently his proposal was little heeded. In 1817 Mr. Charles Tennant, of Glasgow, contributed to the August number of *Thomson's Annals*, 'A Table showing the quantity of Soda (free or combined with Sulphur or Carbonic Acid) contained in the specimen under trial with Sulphuric Acid, containing 10 per cent. real acid. If the specimen under trial consists of 100 grains, the Table of course shows the percentage of Alkali.' His measuring apparatus was a tube graduated to 5 grain division, and he indicated neutrality with red cabbage infusion. He had also used 'a solution of Soda, containing 5 per cent. real alkali, for trying the strength of acids.' Dr. Andrew Ure, one of the first honorary members of the Pharmaceutical Society, contributed a paper to the October number of the volume mentioned, in which he speaks of alkalimetry and the use of litmus as an indicator, giving the results of some estimations made volumetrically. In this paper mention is made of a memoir which the author had submitted to Dr. Henry, of Manchester, in the year previous, in which memoir a full account was given of volumetric methods based on 'the lights recently shed on chemical proportions by Dr. Dalton's atomic theory, and thus made it' (the standard solution) 'represent *not arbitrary*' (as in Descroizelles' method) 'but *absolute* measures.' This is the true basis of volumetric analysis, and Dr. Ure makes good his claim for its invention in a paper read to the Pharmaceutical Society in February, 1844. At that time volumetric analysis had come into general use, particularly on the Continent. Gay Lussac had experimented and devised at least two processes, which are still in use, namely, estimation of free chlorine with arsenious acid, and silver with common salt, the latter method giving origin to the word *titration* applied to the volumetric process, and derived from the French word '*titré*,' standard (of gold or silver). Liebig had devised that beautiful process, now pharmacopœial, for the estimation of hydrocyanic acid, and Bunsen, Schwartz, Fresenius and Will gave the art great impetus by their careful researches. Dr. Mohr, of Coblentz, revised all that had been done by previous investigators, devised new processes, and that burette which is now so much used, thus placing the art in a state of efficiency which has called for little revision. Helpers were not wanting in our own country, but I need only mention the name of Francis Sutton, whose treatise on volumetric analysis has no peer in our language.

"Volumetric analysis was then described as being based primarily on the incontrovertible law of combining proportions, the practice of the art involving several recognized principles which may be generalized as—

"1. A constant and known reaction between the reagent and the substance titrated, the end of the reaction being capable of easy and quick determination.

"2. Standard solutions of reagents whose strength is related to the chemical weight unit—hydrogen.

"3. Employment of apparatus graduated on a decimal system."

The author then proceeded to describe the apparatus required, and the preparation of the standard solutions, referred to the principal features of the reactions, and explained, with numerous illustrations, the basis upon which the necessary calculations are made.

The President moved a hearty vote of thanks to Mr. MacEwan for his paper, and in commending the subject to the attention of the members, referred to the immense labour which the getting up of such a paper with its attendant experiments must have entailed on Mr. MacEwan.

The motion was seconded by Mr. Hill, who regretted that, there being much business before the Association that evening, there was so little time left for the consideration of the paper.

The motion having been heartily accorded, Mr. MacEwan briefly replied.

Mr. J. D. Robertson now proposed "That the annual *réunion* this year take the form of a Conversazione and Ball."

Mr. Turnbull having seconded the motion, it was unanimously approved of, and Messrs. Aitken, Boa, Crowden, C. F. Henry, MacEwan, J. D. Robertson and Turnbull were appointed as a committee to act in the matter.

The queries, as intimated, were then submitted and freely discussed, in which Messrs. Aitken, Boa, Crowden, C. F. Henry, Hill, MacEwan, Duncan M'Laren and Turnbull took part.

The Secretary then gave notice of several queries to be answered at next meeting; and the President having intimated that it will be held on December 5, and that Mr. G. R. Fowler will then read a paper on "Elementary Chemistry," the meeting adjourned.

NOTTINGHAM AND NOTTS CHEMISTS' ASSOCIATION.

The second monthly meeting of the above Association was held in the Sunday School Union Institute, Shakespeare Street, on Friday evening, November 23. There was a good muster of members and associates present. Mr. Councillor Fitzhugh, F.C.S., occupied the chair.

After the reading of the minutes, the President congratulated the members of the Association that at last such arrangements had been made that they would in future be able to meet in the room which they then occupied for the first time. It would be open for the use of associates one night (Friday) every week. He trusted that as it was so centrally situated and comfortable, the associates would avail themselves of this opportunity of improvement and fully appreciate the advantages it would give.

A committee was appointed, consisting of six of the associates, to assist in the arrangements connected with the materia medica, chemical specimens and library that were to be placed in the new room.

The President next introduced Mr. F. H. Spenser, who delivered a most useful and instructive lecture on "The Ear," illustrating his remarks by a large dissecting model.

At its conclusion, Mr. F. Lumby moved a cordial vote of thanks to Mr. Spenser for his able and instructive lecture.

This was seconded by Mr. R. Jackson, supported by the President, and carried.

DOVER CHEMISTS' ASSOCIATION.

The annual meeting of the Dover Chemists' Association was held at the Apollonian Hall, Dover, on the 21st inst., when there was a full attendance of the members. Mr. H. Peake was unanimously re-elected Chairman, and Mr. W. B. Cotterell Hon. Secretary and Treasurer for the ensuing year.

A discussion arose with respect to a retail catalogue emanating from a London firm, which it was stated had been distributed by post throughout the town, and a resolution was passed upon the subject.

The annual supper was held after the business meeting, when Mr. Bottle proposed the health of the President (Mr. Peake), who replied in a suitable manner. A very pleasant evening was spent.

Proceedings of Scientific Societies.

CHEMISTS' ASSISTANTS' ASSOCIATION.

At a meeting of the Chemists' Assistants' Association, held on November 21, Mr. Parkinson, President, in the chair, a paper, on "Glycerine and its Impurities," was read by Mr. F. H. Alcock, of which the following is a *résumé*:—

The author described the various processes for the production of glycerine, including its preparation from emplastrum plumbi, which was the original method adopted by its discoverer, Scheele. The process, as patented by Messrs. Wilson and Payne in 1854, was fully described, viz., that of the dissociation of fats by means of superheated steam. The lime saponification process was also mentioned, as also the means by which the resulting glycerine was purified and concentrated to meet the requirements of medicine and the arts.

The manufacture of hard soap was briefly described in order to show that large quantities of glycerine were formed, which were contained in what is popularly known as soap boilers' waste or soap "lyes." It was with this source that the author wished to deal as fully as possible. Samples of this waste were shown in its original state, filtered and unfiltered, and also a concentrated sample which had been obtained by evaporation by steam heat from 420 pounds weight to 16 pounds. A sample which had been examined showed that this waste consists of a weak solution of glycerine in combination with gelatinous and albuminous matters, caustic soda, carbonate of sodium, chloride of sodium, possessing a disagreeable odour and a dark sherry colour, with a specific gravity of 1·0959, which, however, is very variable.

Many of the patents which have from time to time been taken out with the object of obtaining glycerine from this source were briefly described from the specifications, and allusion was also made to the fact that many more patents were about to be taken out in England, the specifications of which have not yet been printed. The official tests and characters of glycerine contained in the British, German, French (Codex), and United States Pharmacopœias were mentioned, and their object explained and defects pointed out.

Although tests were given for the detection of such substances as sugar, dextrine, gum, and others, which may be purposely added, yet the samples obtained (numbering twelve) from manufacturers, and illustrating the stages of their processes, were only examined for such impurities as might be associated with the method of production.

A tabulated list of results of reagents on the samples examined was shown, which indicated that most samples of medicinal glycerine were very pure, but that pure glycerine from soap lyes was still a problem, the chief objections being colour, smell, chlorides and sulphates.

In the discussion which followed, the President, Messrs. Braithwaite, Bailey, Dodd, Hadfield and Cracknell took part.

Parliamentary and Law Proceedings.

The Sale of Arsenic.

On Tuesday, November 20, Mr. W. Hardy, Deputy-Coroner, held an adjourned inquiry at the Angel Hotel, Mersey Road, Widnes, into the circumstances attending the death of William Williams, a baker, which took place on the 9th inst., from the effects of poison.

After the evidence of the daughter of the deceased had been taken,—

Mr. Alfred Jackson,* said: I am manager for the West Bank Pharmacy Company. I produce the book in which I enter the sales of all poisons sold in the shop. In that book I find an entry dated November 6, and it relates to a man named William Johnson, of Thomas Street, who said he was a grocer, as having bought half an ounce of arsenic, for the purpose of poisoning rats. The entry is signed by himself, "William Johnson." He was introduced by Mr. Thomas Smith, grocer, 84, Mersey Road, who is known to me. He said he knew the man who bought the arsenic, but he did not tell me that he knew him by name. Mr. Smith happened to be in the shop when William Johnson came in.

The Coroner (looking at the book): So far you have complied with the Act of Parliament. Did you not know this William Johnson yourself?—I had seen him a time or two, but did not know his name.

Are you in a position now to say that William Johnson is not William Williams?—I am not.

Have you any doubt that this man is not the man, William Williams, whose death we are inquiring into?—I cannot swear to him. I should like to see a photograph of him, and then I should know. Mr. Smith was rather reluctant at first; but after he heard his tale he signed for him. William Johnson asked Mr Smith to sign for him as knowing him.

Did Mr. Smith tell you he did not know his name?—Yes.

The Act contemplates that you should know the names of persons who ask for poisons. You know I know hundreds of persons by their features; but I do not know them personally, and if they asked me to do something for them, such as certifying that this arsenic was not wanted for the purpose of destroying their lives, I would not do it. If you had known that you should have said to Johnson, "Mr. Smith cannot introduce you here, because he does not even know your name."—I knew the man very well by sight.

You have already told me that Mr. Smith said he did not know his name, but that he knew him by sight. The Act of Parliament says that the person who wants to buy the arsenic as well as the person who introduces him shall be known to the seller. Of course, if it had rested there; if Mr. Smith had said "I do not know you by name, but I know you by sight," you are not bound to serve him. In your presence this gentleman introduces him. He said he only knew him by sight, and that is why I say you should have been more careful, and that is why I say it is not complying with the Act, though I should be extremely sorry to see any action taken upon it.

By the Foreman: I do not remember on any previous occasion selling poison to this person.

The Foreman: It has been stated that he got poison at your shop previously.—I have never heard of this man being served with a pennyworth of white precipitate at our shop. There has not been a boy employed in the shop since June.

The Coroner: The Act of Parliament is an excellent one. It should be strictly complied with, and if it had been broken in the manner in which I should have thought it necessary to call the attention of the police to it, the penalty would have been enforced in this case.

* The name of this witness does not occur on the Register of Chemists and Druggists for 1883.—Ed. Ph. J.

Mr. Thomas Smith said: I am a grocer, residing at Widnes. On the 6th inst., I was standing in the West Bank Pharmacy when the deceased came in. Mr. Jackson asked me if I knew him, and I said I did not, though I had seen him before.

The Coroner: Can you tell me who the man was?—No, I did not know him.

Have you any doubt that the man, William Johnson, who asked for arsenic in the West Bank Pharmacy was not the William Williams about whose death we are now inquiring?—I cannot say.

Do you think that this man, William Johnson, who purchased the arsenic was not William Williams?—I have heard since that he was.

So has everyone in Widnes and in the county of Lancaster.—Well, I do not know him.

What sort of a looking man was he?—He was a tall, thin person, with white hair. I think when he came in he asked to be served with twopennyworth of arsenic to kill rats with. Mr. Jackson told him he could not sell him any unless some person would sign for him as a witness. The deceased thereupon turned to me, and said, "Mr. Smith will do—won't he?" He then asked me if I had any objection to sign, and I said, "No." I told Mr. Jackson that I knew him by sight, but not by name. Mr. Jackson asked me if I would have any objection to sign the register for him, and I said "No," and did so.

The Jury returned a verdict of "Temporary insanity"

Review.

Dispensatory of the United States of America. By Geo. B. Wood and Dr. Franklin Bache. Fifteenth Edition. By H. C. Wood, M.D., Joseph P. Remington, Ph.G., and Samuel P. Sadtler, Ph.D., F.C.S.*

A work that has reached its fifteenth edition and of which it can be truly said that the copies hitherto sold "are to be numbered by the hundreds of thousands" might in some respects be deemed to be above criticism. But it is not every work that can stand the ordeal of such a success, especially when dealing with a subject that undergoes continual change and development. Too frequently succeeding editions fall away from the high standard of perfection which in the first edition won for the book its acceptance, and after existing for a longer or shorter time upon its first reputation the once famous work becomes ingloriously obsolete. Such a fate not long since appeared to await the book under notice in the not very remote future. But the circumstance that might have given it the *coup de grâce*,—the issue of a profoundly modified form of the work of which it is put forward as the exponent,—has been utilized for its resuscitation, and under its new editors it has started with a new lease of life. It is fifty years since the first edition of the 'United States Dispensatory' was issued, and when ten years ago the fourteenth edition was published the surviving editor was eighty years of age, and physically unequal to the task of revising it. The new edition, however, has had the advantage of the services of three competent editors, one for each branch of the subject matter, who have supplied a large quantity of ably written fresh matter, rendered necessary by the introduction of new substances or preparations into the Pharmacopœia, and in many instances have practically rewritten other articles in order to bring them up to date.

Most of our readers are aware of the nature of the Dispensatories with which our Transatlantic brethren are so richly supplied. The book under notice was the earliest to appear, and in its present form presents an extremely practical and useful commentary upon not only the United States Pharmacopœia, but the British

* Philadelphia and London: J. B. Lippincott and Co. 1883. Pp. i.-viii., 1-1928.

as well, since it deals with all the articles official in both works. This commentary includes as a rule the history and origin of the several drugs or chemicals, a judicious summary of what has been written upon them, and notes on their properties; in the case of preparations, where necessary, the chemistry and pharmacy are discussed; and in most cases there is a valuable note on the medical properties and uses. A very praiseworthy feature is that where the statements of other authors are quoted references are given to the original papers; sometimes these references might be a little more precise, as in the case of journals which like our own have had the fortune or misfortune of being divided into series, but on the whole they are sufficiently definite.

The present edition differs materially in arrangement from preceding ones, consequent upon the incorporation of the materia medica with the preparations in the new United States Pharmacopœia. A considerable number of fairly executed illustrations have also been introduced. After the official articles have been dealt with, another couple of hundred closely-printed pages are devoted to drugs and medicines not official, and then follow sections on the tests, various tables, a list of all American mineral springs of known medicinal value, together with results of analyses of their waters, and a full index, which is rendered more useful by the presence of the German names as well as the Latin and English.

The work is not without faults; it would be wonderful if such a mass of statements did not include some that were open to criticism, and we had noted some down with the intention of referring to them. But we have come to the conclusion that this would be to give them undue importance, since we are of opinion that the book, as a whole, is one that is most worthy to hold a place in the pharmacist's select library.

Obituary.

JOHN ELIOT HOWARD, F.R.S.

We greatly regret to have to record the death of Mr. John Eliot Howard, on the 22nd of November, after a very short illness, at his residence, Lord's Meade, Tottenham.

Mr. Howard was born on the 11th of December, 1807. He was the son of Mr. Luke Howard, F.R.S., who towards the end of the last century was a partner with Mr. Allen in the pharmacy at Plough Court, and subsequently founded the well-known firm of Howards and Sons, chemical manufacturers, at Stratford, but who was perhaps better known in the scientific world on account of his meteorological investigations. After leaving school, Mr. John Eliot Howard joined his father in the business at Stratford, and he remained in connection with it until his death. He, however, was able to find time to indulge his interest in science, and in addition to the study of chemistry, he devoted many years of his life to investigations into the botanical and natural history of the genus *Cinchona*, with which his name will continue to remain associated.

In the course of his quinological studies, Mr. Howard edited the unpublished work of Pavon, the 'Nueva Quinologia,' and illustrated it with a magnificent series of plates drawn by the well-known artist, Mr. Fitch, from Pavon's specimens at Madrid. When the Government of India introduced cinchona cultivation into that country, assisted by the untiring zeal and energy of Mr. Clements Markham, and of his able coadjutors, Messrs. Spruce and Cross, Mr. Howard, seeing the immense public importance of the work, generously gave all the assistance in his power without a thought of recompense, and his services were in 1873 acknowledged in a special vote of thanks from Her Majesty's Government. Mr. Howard devoted the labour of years to the study of the various problems which suggested themselves while this great enterprise was being carried out, and his work on the 'Quinology of the East Indian Plantations,' in which he embodied the result of his investigations, will always remain an authority on these questions. He also communicated numerous papers upon similar subjects to the Pharmaceutical and Linnean Societies, to the British Pharmaceutical Conference, and to this and various foreign journals. Mr. Howard was also a liberal donor of specimens to the Museum of the Pharmaceutical Society, many of them being of special value as illustrative of papers read at Evening Meetings and published in the *Pharmaceutical Journal.*

Mr. Howard devoted much time and thought to the questions of the relation of religion and science that occupy the minds of so many at the present day. An unhesitating believer in Christian doctrine, he never doubted that a reconciliation is to be found for all that is true in science with the truths of Revelation. Various papers by him on these subjects may be found in the Journals of the Victoria Institute, of which he was a Vice-President.

Mr. Howard joined the Pharmaceutical Society in 1853, and continued a member until his death. On the 6th of October last, at the first Evening Meeting of the Society for the present session, Mr. Howard received from the hands of the President, as representing the committee of adjudicators, the Hanbury Gold Medal, in recognition of the value of his scientific investigations respecting an important article of materia medica. Those who were present on that occasion could little have anticipated that he would so soon be taken from the scene of his earthly labours while still in full vigour of mind and body in spite of his advanced age.

Mr. Howard was elected a Fellow of the Royal Society in 1876, and was also a Fellow of the Linnean Society, a Corresponding Member of the Société de Pharmacie de Paris, and also a member of numerous other scientific bodies on the Continent.

The deceased gentleman married Maria, the daughter of the late Isaac Crewdson, of Kendal, and leaves a large circle of children and grandchildren to lament his loss.

Mr. Howard was buried on Wednesday last in Tottenham Cemetery, and the funeral was attended by a large number of persons desirous of testifying their respect for the deceased. Among the representatives of scientific bodies with which Mr. Howard had been connected were the President of the Pharmaceutcal Society, Mr. Walter Hills, Professor Bentley, Professor Attfield, Mr. E. M. Holmes, etc.

OL. RUSCI.

Sir,—Mr. MacEwan's paper on "Ol. Rusci" in the *Pharmaceutical Journal*, p. 381, points to the desirability of pharmacists when rambling in foreign lands securing true samples of any article of recognized remedial value peculiar to the country, with the view of enriching the Museum of the Pharmaceutical Society, for future reference, and also of adding to the number of available agents for the cure of disease.

During my stay in St. Petersburg, in connection with the International Congress of 1874, I was desirous of procuring a specimen of the true ol. rusci, and with that object begged the assistance of a pharmacist from the interior of Russia. The difficulty mentioned by Mr. MacEwan of getting the true article was at that time fully recognized, and it was also generally accepted that its export was prohibited, but I am not, even at the present time, able to vouch for the correctness of that report. A portion of the sample then obtained, of the genuineness of which I have not the slightest doubt, was placed in the Society's Museum. Since that period many inquiries have reached me in reference to this article, and having visited Russia a second time in 1881, the difficulty in connection with the subject again recurred to me; however, I did succeed in procuring a larger supply of the true ol. rusci. It may perhaps not be generally known that it is this oil which gives that peculiar, penetrating and persistent odour which characterizes Russian leather.

Although not prepared to express a positive opinion as to the origin of the name, I think that "rusci" is most probably a corruption of "russicum;" the transition of one to the other is easy and almost natural. The Russian name for it, as pronounced by the natives, sounds to a person not conversant with the Russian language as "dagget." It was at a very early period employed in medicine under the several names of ol. betulinum, russicum, rusci, muscoviticum and lithuanicum. It will be observed that excepting betulinum, which indicates its being obtained from the betula or birch, all the names point to a Russian or Polish origin.

I regret that Mr. MacEwan did not apply to me, as I was in a position to and would gladly have supplied him with a larger quantity of the true ol. rusci for the purpose of his experiments.

During my stay in Vienna at the International Pharmaceutical Exhibition in August last, I learnt that this remedy was largely used in the Vienna hospital, and I was anxious to see the particular form of eczema in which ol. rusci was used, and the usual method of applying it. For this purpose I visited the skin ward of the general hospital, called the Kaposi ward.

Kaposi, in his recent work,* speaking of the intolerable itching in eczema papulosum (a form of eczema in which there is little secretion), recommends one or two remedies and then says, "Brushing over with tinct. rusci acts still more favourably."

Professor Kaposi is the successor of Hebra, who obtained great eminence in the cure of skin diseases. Through the courtesy of Dr. Loosgarten, one of the assistants of Professor Kaposi, I was invited to accompany the physicians through the several wards and saw that particular condition of eczema in which ol. rusci and its preparations show their best effects. I may also add that its use is attended with great benefit in ringworm. One of the preparations of ol. rusci alluded to is a solution of the oil to which the name of tinct. rusci is given.

I hope that Mr. MacEwan's paper will serve to direct the attention of those whom it may concern to an article of established reputation in Russia, Poland and Austria, with other northern countries, as a curative in certain conditions of that intractable skin disease to which the general term of eczema is applied, and be the means of adding one more article to our active materia medica for the alleviation of human misery.

LIQUID EXTRACT OF CINCHONA.

Sir,—When some time ago you inserted my letter headed "A Query requiring an Answer," I could scarcely have conceived that my question would have drifted from its legitimate channel into a discussion upon the merits or demerits of Mr. Battley's as compared with the Pharmacopœia preparation of liquid extract of cinchona.

Looking at the matter from my standpoint the conclusions to be arrived at are, I respectfully submit, as follows:—

Firstly. That the Ext. Cinch. Liq., B.P., is a misnomer, and reflects as much credit(?) upon its author or authors as do many preparations found in that erudite and impractical compilation.

Secondly. That Mr. Battley's preparation, though admittedly superior to that of the B.P., does not represent, really and truly, what it is stated to do on the label, and,

Thirdly. That Mr. Battley, while professing to divulge his process, did not "disclose the whole of the operations," did "not enter into details of manipulation and elimination" "which constituted the essence and completeness of his preparation"!

No one can admire and appreciate the late Mr. Battley's professional knowledge and its results more than I have done, and still do; but it is to be regretted that while he truthfully stated facts, he appears to have stopped short of stating the whole truth and nothing but the truth.

However, as we are about, I believe, to be honoured with a new Pharmacopœia, it is devoutly to be hoped that practical experience will be brought to bear upon it, and that nothing will be introduced into it which will not bear the most crucial test.

I still "want to know" how, if it be impossible to extract from cinchona bark its alkaloids, upon which its medicinal virtue is said to depend, without acids, an aqueous preparation can contain the entire constituents of the bark, as Battley's liquor professes, and the B.P. extract is said to do.

50, *Elgin Crescent, W.* PERCY WELLS.

TINCTURE OF NUX VOMICA FOR THE EXTRACT.

Sir,—In answer to Mr. Tanner's letter in the *Pharmaceutical Journal* of November 17, I beg to state that I do not make my own extract of nux vomica, and I do not think making a small quantity of extract either profitable or likely to give a fair or average percentage, but I use that sent out by wholesale houses in the ordinary course of business. I consider uniformity of strength of far more importance than colour, taking into consideration its potency, and the small quantity which we sell to the public as tincture of nux vomica. My authority for the quantity of extract I used is Mr. Peter Squire (*vide* 'Squire's Comp., B.P.,' 12th edit., p. 211), who gives 16 ounces of seeds yield 1 ounce of extract. I think no better reason could be brought forward for change of formula than that produced by Mr. Tanner, he having found about 20 per cent. of extract and Mr. Squire about 6·25 per cent., rather a wide descrepancy. The only explanation I can think of is that the former had a sample rich in extractive matter and the latter the reverse.

Preparing tincture from extract is not quite unknown even in the the present B.P., and the deposit on the sides and bottoms of bottles is not peculiar to tinctures made from extracts, but may be noticed in many which are prepared in the ordinary way, although I have never heard of it being put forward as an objection to the method of preparation.

If Mr. Tanner can steam, dry rapidly, and powder four ounces of seeds with the same facility that he can weigh 120 grains of extract, I must own, with all humility, that I cannot.

London. J. HICK.

Inquirer.—If the preparation is received, as is usually the case, as a "triple" water, it should be diluted in proportion.

Creon.—The article is the subject of a patent.

G. Nind.—We do not think that the restatement of your proposition is plainer than the original statement, or that the correspondent referred to failed to understand it.

"Apprentice."—(1) *Aster Trifolium.* (2) *Viola tricolor.* (3) *Hypericum perfoliatum.* (4) *Achillea Millefolium.* (5) *Trifolium procumbens.* (6) *Geranium Robertianum.*

J. F. Brown.—We are not acquainted with any published analysis of malt combings. Perhaps some reader may be able to furnish a reference to one.

A Member.—Hydrochloric or sulphuric acid would be equally efficacious.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Conroy, Hodgkin, Dyer, Pharmacist, Quercus, A. E. I.

REPORT UPON THE PHARMACEUTICAL PREPARATIONS OF NUX-VOMICA.*

(*Continued.*)

II. NOTES AND SUGGESTIONS UPON TINCTURE OF NUX VOMICA.

BY WYNDHAM R. DUNSTAN,

Assistant Lecturer in Chemistry and Physics to the Pharmaceutical Society and Demonstrator of Practical Chemistry in the School of Pharmacy;

AND F. W. SHORT,

Assistant Demonstrator of Practical Chemistry in the School of Pharmacy.

In a former paper (*Pharm. Journ.*, [3], xiv., 290) we have shown by analysis that commercial tinctures of nux-vomica vary considerably in alkaloidal strength. This difference is no doubt in the first instance due to a variation in the amount of alkaloid contained in the seeds of *Strychnos Nux-vomica* now in commerce, the existence of which we have already proved in a previous communication to this Society (*Pharm. Journ.*, [3], xiii., 666 and 1053). There are, however, other possible causes which might contribute to the inconstant result. Foremost among these is the possibility of alcohol containing more water than rectified spirit having been employed in the manufacture of the tincture; this conjecture might appear to be supported by a relation which is noticed in the table of analyses published in our previous paper upon this subject. For it is here observed that in certain cases high specific gravity is associated with a large percentage of alkaloid. The important assumption underlying this conjecture is that a dilute alcohol extracts more alkaloid than a stronger alcohol; but, as far as we can discover, this has never been experimentally substantiated. Nevertheless, various suggestions based upon this assumption have been made for the employment of a weaker alcohol than rectified spirit for the preparation of the tincture, and some of these suggestions have been adopted in foreign pharmacopœias.

In order to determine by direct experiment the extractive power of alcohol of different strengths the following experiments were made. Five gram quantities of nux-vomica in impalpable powder were macerated for three days with 50 cubic centimetres of alcohol containing different proportions of water, the mixtures being frequently agitated. Maceration was adopted, because percolation with alcohol containing more water than proof spirit is rendered practically impossible owing to swelling of the seeds and consequent c ogging of the percolator, occasioned by the action of the water upon the mucilaginous constituents, and it was deemed important that the experiments should be strictly comparative. And further, had ordinary percolation been adopted and a larger amount of alkaloid been found to be extracted by the weaker spirit, there would be the alternative that this was due, not to the greater solubility of the alkaloidal salts in the weaker spirit, but to the longer time during which the seeds were in contact with this spirit, for with nux-vomica the rate of percolation is inversely as the quantity of water present. After maceration 40 cubic centimetres of the tincture were filtered off and the amount of total alkaloid determined by a process which has been described in general outline in our former paper upon tincture of nux-vomica.

In detail the process is as follows. The quantity of tincture to be estimated, usually 50 grams, is evaporated almost to dryness upon the water-bath in a beaker; to this residue 25 c.c. of chloroform are added, but inasmuch as the residue will not dissolve in chloroform alone 15 c.c. of dilute sulphuric acid (5 per cent.) are added, and the mixture is poured, after gently warming, into a separating funnel, well shaken, and the chloroform run off; the latter is extracted with a little more acid if necessary. The acid liquid, which contains the alkaloid, is rendered alkaline with ammonium hydrate and agitated with 15 c.c. of chloroform, which is separated and filtered if necessary. The alkaline liquid is again shaken with chloroform and the latter run off. The mixed chloroformic solutions, which should be perfectly clear, are evaporated to dryness upon the water-bath, and after exposure for one hour at this temperature the residue of total alkaloid is weighed.

In many cases the residue from the evaporation of the tincture may be directly dissolved in dilute sulphuric acid, the liquid rendered alkaline with ammonium hydrate and the alkaloid extracted with chloroform. In certain cases, however, the alkaloid obtained in this way contains a trace of colouring matter, but a perfectly pure residue is obtained by the method described at length above.

The following table shows the results of the experiments:—

TABLE 1.

Proportion of rectified spirit to water (by volume).	Quantity of total alkaloid in 40 c.c. of tincture.	Percentage of total alkaloid extracted from the nux-vomica.
100 : 0 (rectified spirit)	0·078	1·95
100 : 25	0·088	2·20
100 : 33	0·088	2·20
100 : 50	0·089	2·22
100 : 60 (proof spirit)	0·086	2·15
100 : 100	0·074	1·85

The marcs from these tinctures were found in all cases to be distinctly bitter, and hence in no case had the exhaustion been complete. The above results show that water mixed with rectified spirit in any proportion up to and including proof spirit extracts more alkaloid than rectified spirit alone; but when the water rises above the proportion contained in proof spirit the extractive power for alkaloid again diminishes. The obvious conclusion to be drawn from these experiments is that proof spirit should be substituted for rectified spirit in the preparation of tincture of nux-vomica. But there is one strong reason for suggesting the use of 100 volumes of rectified spirit mixed with 25 volumes of water. For although the extractive power of these two spirits may be said to be the same, the use of the stronger spirit has this advantage over proof spirit, that it percolates very much more freely, while, owing to the larger proportion of water in the proof spirit, the percolation occupies a much longer time and the percolator is very apt to clog.

Rother (*Am. Journ. Pharm.*, lv., 1; *Pharm. Journ.* [3], xiii., 643) has proposed the use of sodium chloride in the preparation of tincture of nux-vomica,

* Read at an Evening Meeting of the Pharmaceutical Society of Great Britain, December 5, 1883.

claiming that more complete exhaustion is by this means obtained; but this statement is not supported by any alkaloidal determinations. We have therefore experimentally studied the influence of sodium chloride upon the extraction of nux-vomica by alcohol. Rother recommends the use of spirit the strength of which is represented by equal volumes of rectified spirit and water; but in view of the results obtained above, we have employed 100 volumes of rectified spirit to 25 volumes of water.

Five grams of nux-vomica were macerated for three days with 50 c.c. of spirit containing 100 volumes of rectified spirit and 25 volumes of water, in which was dissolved 0·7 gram of sodium chloride. Three experiments were made. In the first experiment the maceration was continued for two days; in the second and third experiments for three days. The results are recorded in Table II.

TABLE II.

Proportion of rectified spirit to water. (By volume).	Percentage of NaCl dissolved in spirit.	Amount of total alkaloid in 40 c.c. of tincture.	Percentage of alkaloid extracted from the nux-vomica.
100 : 25	1·5	0·087	2·18
100 : 25	1·5	0·102	2·55
100 : 25	1·5	0·100	2·50

As maceration is but an imperfect process of exhaustion, two experiments were made by percolation, spirit of the above strength being employed in one experiment and the same spirit containing 1·5 per cent. of sodium chloride in the other. Five grams of the finely powdered seeds being percolated with 50 cubic centimetres of the spirit. The results are shown in Table III.

TABLE III.

Proportion of rectified spirit to water. (By volume).	Percentage of NaCl dissolved in spirit.	Amount of total alkaloid in 50 c.c. of tincture.	Percentage of alkaloid extracted from nux-vomica.
100 : 25	0	0·125	2·5
100 : 25	1·5	0·130	2·6

In the first experiment the marc was slightly bitter, but in the second, where sodium chloride was used, the marc was entirely free from bitterness, indicating complete exhaustion. It will be seen from these experiments that a spirit made by the addition of 25 volumes of water to 100 volumes of rectified spirit extracts nearly the whole of the alkaloid from nux-vomica when used in the proportion of 1 of nux-vomica to 10 of the spirit. When sodium chloride to the extent of 1·5 per cent. is dissolved in spirit of the above strength the whole of the alkaloid is withdrawn from the seeds, the sodium chloride no doubt acting, not chemically as Rother maintains, but physically, by softening and dissolving the albuminous matter of the seeds, as it is known to do in other cases. As the ultimate gain effected by the use of sodium chloride is but small it becomes a question for consideration whether it should be adopted in practice.

It has frequently been suggested that tincture of nux-vomica should be prepared by dissolving a definite quantity of extract of nux-vomica in alcohol. Apart from any practical difficulties that may stand in the way of this suggestion, it is based upon the supposition that extract of nux-vomica is a product of definite alkaloidal strength, and therefore that when a tincture contains a known quantity of the extract it may be considered as uniform in action and composition. This supposition, as we shall subsequently prove, is entirely erroneous, extract of nux-vomica being in reality very variable in alkaloidal strength, just as the tincture is, when prepared in the ordinary way. The new edition of the United States Pharmacopœia contains a process for making tincture of nux-vomica constant in the amount of extract which it contains. But, it appeared to us that, having an extract known to contain a definite quantity of alkaloid to work with, there would be a distinct advantage, other things being equal, in preparing the tincture from such an extract. We therefore made experiments to determine whether by any simple means an extract of nux-vomica could be prepared that would wholly dissolve in alcohol, forming a solution that would not deposit upon keeping.

Experiment 1.—An extract of nux-vomica was prepared with rectified spirit and evaporated upon the water-bath until it had the consistence of a soft extract. Ten grains of this were dissolved with the aid of a gentle heat in one ounce of rectified spirit, by which means a perfectly clear solution was obtained, but in twenty-four hours this had deposited a white sediment.

Experiment 2.—An extract was prepared in the same way as in experiment 1, but ten grains were dissolved in one ounce of a mixture of two volumes of rectified spirit and one volume of water with the aid of a gentle heat. A large quantity of oily matter refused to dissolve and the tincture soon deposited a copious yellow sediment.

Experiment 3.—The same extract was used as in the former experiments, but the solution of ten grains was attempted with one ounce of proof spirit. Some oil remained insoluble and the tincture deposited an abundant yellow sediment.

Experiment 4.—The extract was prepared with rectified spirit, evaporated upon the water-bath, and exposed for eight hours. Ten grains of this extract dissolved readily in one ounce of rectified spirit, but the tincture deposited a small quantity of brown sediment.

Experiment 5.—The extract in this case was prepared with proof spirit and evaporated to a soft consistence. Ten grains of this were dissolved in one ounce of proof spirit, yielding a nearly clear tincture, which deposited very slightly after twenty-four hours.

The above experiments indicate that there is no very ready means of obtaining a perfectly stable tincture of nux-vomica from the solution of the extract in alcohol, although experiments 4 and 5 might possibly be modified to yield good results. However, we are now engaged in elaborating a simple and direct method of preparing tincture of nux-vomica of definite strength upon different lines, and hope to bring our results before this Society at a future meeting.

Our thanks are due to Professor Attfield, F.R.S., for having permitted this investigation to be carried out in the Laboratories of the Pharmaceutical Society, and to the British Pharmaceutical Conference for having aided the work by a grant from its Research Fund.

[*The discussion on this and the following paper is printed at p.* 456.]

REPORT UPON THE PHARMACEUTICAL PREPARATIONS OF NUX-VOMICA.*

(*Continued.*)

III. ON EXTRACT OF NUX-VOMICA.

BY WYNDHAM R. DUNSTAN,

Assistant Lecturer in Chemistry and Physics to the Pharmaceutical Society and Demonstrator of Practical Chemistry in the School of Pharmacy;

AND F. W. SHORT,

Assistant Demonstrator of Practical Chemistry in the School of Pharmacy.

The only analysis, as far as we know, that has been published of extract of nux-vomica is that made by Dragendorff,† who records that he found in one sample of the extract 7·3 per cent. of total alkaloid, and in another 8·5 per cent. Our first experiments upon this subject were directed to the discovery of a simple and accurate method for the estimation of the total alkaloid in the extract. In a previous paper (*Pharm. Journ.*, [3], xiv., 292) we described a process of this kind for the determination of the total alkaloid in tincture of nux-vomica, which consisted in evaporating the tincture to dryness, and then dissolving the residue in a mixture of chloroform and dilute sulphuric acid. We first tried a similar process in the case of the extract, but it was found that although the commercial extract was wholly dissolved by the above mixture, the alkaloid subsequently extracted by chloroform, after the addition of ammonium hydrate, was slightly impure.

We therefore made further experiments, which led to the adoption of the following process:—About one gram of the extract is dissolved in a strong solution of sodium carbonate with the aid of a gentle heat. This solution is extracted with two consecutive 15 c.c. of chloroform. The mixed chloroformic solutions are extracted with two consecutive 15 c.c. of dilute sulphuric acid (5 per cent.), and from the mixed acid solutions, which should be filtered if necessary, the total alkaloid is extracted after the addition of ammonium hydrate by agitation with chloroform, two separate quantities of 15 c.c. being generally sufficient. The clear chloroformic solutions are evaporated to dryness upon the water-bath, and the residue of total alkaloid weighed after exposure for one hour. The alkaloidal residue thus obtained was shown to be pure by applying the ammonia-tannin process, which we have fully described in a former paper. The following is a typical result:—(α) amount of alkaloid originally found; (β) amount of pure alkaloid obtained by ammonia-tannin process.

α—0·164.
β—0·161.

Twelve commercial specimens of extract of nux-vomica were now analysed, the total alkaloid being estimated in the manner above described and the strychnine by a method of precipitation as ferrocyanide, which we have described at length elsewhere (*Pharm. Journ.*, [3], xiv., 290); the brucine was estimated by difference. In addition the quantity of "moisture" indicated by the loss at 100° C. has in all cases been determined. The results are recorded in the following table:—

Analyses of Extracts of Nux-vomica.

No.	Percentage of moisture.	Percentage of total alkaloid.	Percentage of strychnine.	Percentage of brucine.
1	16·7	15·15	6·63	8·52
2	19·7	15·64	7·44	8·20
3	15·5	10·32	4·19	6·13
4	15·7	15·16	7·08	8·08
5	16·0	12·49	5·53	6·96
6	13·9	12·53	5·17	7·36
7	13·8	12·25	4·87	7·38
8	17·8	17·54	7·52	10·02
9	13·6	15·78	6·41	9·37
10	16·0	15·94	6·84	9·10
11	17·3	16·24	5·81	10·43
12	15·9	17·12	8·58	8·54

It will be seen that, just as in the seeds and tincture, so in the commercial extracts of nux-vomica, our analyses indicate a serious want of uniformity in the alkaloidal content. This variation in the extracts might arise at least from two causes: (1) the difference in alkaloidal content among the seeds of commerce; (2) the practice, which might appear from some observations subsequently recorded to be far from uncommon, of removing the oil which separates during the manufacture of the extract.

When an alcoholic tincture of nux-vomica is evaporated a comparatively large quantity of oil separates as the evaporation proceeds, for this oil while soluble in alcohol is insoluble in water. Now an examination of the oil separated in this way has shown us that it contains alkaloid, both as strychnine and brucine, and hence its removal from the extract, in any case illegitimate, is accompanied by abstraction of alkaloid and consequent diminution in the total content. The presence of oil in an extract may easily be detected by warming with water or dilute alcohol, and upon cooling the oil will separate and float upon the surface of the liquid. Some of the commercial extracts, the analysis of which has been given above, failed to yield more than a mere trace of oil when tested in this way. This may be due either to the abstraction of oil during manufacture or to the use of a very dilute spirit in the preparation of the extract. We have found that an extract prepared in the latter way contains little oil. If the absence of the oil is due to this second cause and a spirit about the strength of proof spirit has been employed in the manufacture of the extract, from results published in our foregoing paper more alkaloid should be extracted in this way. In the case of one of the extracts examined, namely that which is richest in total alkaloid, this would seem to be the case, for we found that this extract contained no oil; although this result might have been brought about by the actual removal of the oil during manufacture, the quantity of oil removed being large in proportion to the small quantity of alkaloid which it contains. The actual method of manufacture being unknown to us, the truth of these conjectures must necessarily be uncertain; but, be the cause what it may, we have shown beyond doubt that there is a serious want of uniformity both in the extracts and in the method of their preparation. In a future communication we shall hope to bring forward a simple and direct method for the preparation of an extract of nux-vomica which shall be constant in alkaloidal strength.

* Read at an Evening Meeting of the Pharmaceutical Society of Great Britain, December 5, 1883.

† 'Die Chemische Werthbestimmung,' p. 72.

We are indebted to Professor Attfield, F.R.S., for allowing the work connected with this investigation to be carried on in the Laboratories of the Pharmaceutical Society, and have also to acknowledge a grant from the Research Fund of the British Pharmaceutical Conference in its aid.

TINCTURE OF CINCHONA.*

BY EDW. GRINDLE HOGG,

Pharmaceutical Chemist.

Published statements as to the exhaustion of the bark by the spirit in making the above preparation being contradictory, it was suggested to me that it might be of interest to make some experiments as an endeavour to settle the divergent opinions already expressed.

In the 'Year-Book of Pharmacy' for 1878, in a paper entitled "A Comparison of the Strength of some of the Cinchona Preparations," Mr. Ekin states that having operated upon a bark in which he found nearly 2 per cent. of total alkaloid he obtained a tincture by the B.P. process, 500 minims of which contained the whole of the alkaloid of 100 grains of the bark. On the other hand, at an Evening Meeting, held in March last, Dr. Paul is reported to have stated:—"That he could not confirm the statement made by Mr. Ekin, but that he (Dr. Paul) found when he repeated the Pharmacopœia process on the same bark he got a result nearly as good the second time as the first in regard to the proportion of alkaloid."

I have to record the result of an examination of four different samples of cinchona bark, tending to prove that Dr. Paul's statement, startling as it may have appeared, was by no means overdrawn.

My mode of proceeding has been as follows. First to estimate the amount of total alkaloid in the bark, then to prepare a tincture strictly according to the official directions, and estimate the amount of alkaloid in it; finally, as a check, I have, in two instances, estimated the amount of alkaloid remaining in the marc. The process of estimation adopted has been the same in each sample, both of bark and tincture, so that the results are strictly comparative. The method is that of H. Meyer (*Archiv d. Pharm.*, [3], xx., 721; *Journ. Chem. Soc.*, ccxliv., 388), which is based upon an examination of the principal published processes and shown by the author's results to be the simplest and most accurate process yet proposed. I have introduced a slight modification to be presently described. Meyer directs 10 grams of bark finely powdered to be intimately mixed with 12 grams of slaked lime, and boiled for one hour in a tared flask with 180 c.c. of strong alcohol. When perfectly cool the centents of the flask to be made up to 190 grams with strong alcohol and set aside to deposit. One hundred c.c. is then filtered off. The specific gravity of the filtrate will average 0·84 and this 100 c.c. represents the total alkaloid from 5 grams of the bark. To this alcoholic solution is added 20 c.c. of 1 per cent. sulphuric acid, and the whole evaporated on a water-bath to about 10 c.c. After cooling 10 c.c. of distilled water is added and the mixture filtered into a separating funnel. Dish and filter are repeatedly washed with distilled water until the washings cease to give a precipitate with picric acid. Fifty c.c. of chloroform is then added and caustic soda to strong alkaline reaction. The mixture is well shaken, the chloroform allowed to separate, run into a tared flask and recovered by distillation. The flask is heated in a hot air chamber at 212° F. for one hour, cooled over sulphuric acid and weighed. The shaking of the mixture in the separating funnel with chloroform is repeated as long as any weighable residue is obtained, three operations being generally found sufficient.

The only departure that I have taken from this method is as follows. Instead of boiling 10 grams of bark and 12 of lime with 180 c.c. of alcohol, as Meyer suggests, and taking half the solution obtained, I have taken 5 grams of bark with 6 of lime and exhausted the mixture with 100 c.c. of strong alcohol in the apparatus for continuous extraction suggested by Messrs. Dunstan and Short in the *Pharmaceutical Journal* of February 17 last, making sure of having thoroughly exhausted the bark by continuing the extraction until the spirit that dropped through ceased to give a precipitate with picric acid. The operation thus conducted occupied about one hour. The principal reason that led me to adopt this modification was that I found boiling the mixture of bark, lime and alcohol in a flask, as Meyer directs, to be attended with considerable difficulty on account of the bumping which takes place when the boiling point is reached. In the estimation of tincture, 50 c.c. were taken, evaporated on a water-bath till the spirit was got rid of, the residue mixed with slaked lime, dried and extracted as described. Proceeding as above the results obtained may be tabulated as follows:—

	Grains of total alkaloid in 100 grains of bark.	Grains of quinine in 100 grains of bark.	Grains of total alkaloid in volume of tincture (500 min.) representing 100 grains bark.	Grains of total alkaloid remaining in marc.
No. 1	3·98	not estimated	1·22	2·76
„ 2	4·96	3·9	1·89	2·65
„ 3	7·10	4·4	2·15	4·95
„ 4	4·25	not estimated	2·87	1·2

The figures in column 3 in the case of samples 2 and 4 were obtained by experiment, the remainder by difference.

The question arises, Were the barks used of the kind and qualities indicated by the Pharmacopœia, according to which we are directed for the preparation of tincture to take of the bark of *Cinchona Calisaya* in flat pieces or in quills, containing not less than 2 per cent. of quinine as estimated by the official process? Sample No. 1 was a trade sample of flat yellow cinchona bark, and these, it is well known, as a rule do not come up to the Pharmacopœia standard, not being the true *Calisaya* bark and containing, often, little or no quinine. No. 2 was a specimen of quilled bark, such as I believe is obtainable in commerce, and was identified by Mr. Holmes as true *Calisaya*. No. 3 was a flat bark, not a true *Calisaya*, although rich in alkaloid, the greater portion of which was found to be quinine, purposely estimated both in this and in the previous bark by the official process, the quilled specimen yielding 3·9 per cent., and the flat 4·4 per cent. of this alkaloid. The result as regards extraction of total alkaloid in the tincture was no better than that obtained from the inferior barks.

* Read at an Evening Meeting of the Pharmaceutical Society of Great Britain, December 5, 1883.

The best exhaustion obtained was with specimen No. 4. This bark was of the same character as No. 1; but the tincture was prepared by the method I am in the habit of using, viz., moistening the bark with a small quantity of the spirit, packing in a percolator, provided with a tap, pouring on more spirit and allowing to stand about twelve hours with the tap closed, then permitting the spirit to drop only very slowly at first, adding the remainder, pressing and finishing in the usual manner.

Since sending in this paper, Mr. Holmes supplied me with a sample of flat *Calisaya* bark from a specimen in the Museum of this Society. The results obtained were as follows:—

Grains of total alkaloid in 100 grains of bark.	Grains of total alkaloid in volume of tincture (500 minims) representing 100 grains of bark.	Grains of total alkaloid remaining in marc.
2·4	0·75	1·65

These figures fairly coincide with those previously given, but are of interest as this bark appears to be as nearly as possible exactly of the kind and quality indicated by the Pharmacopœia.

It might, perhaps, be suggested that the alcohol exhausts the bark of the quinine, but not so readily of the other alkaloids; but the results given above, obtained with barks rich in quinine, do not support this theory.

The experiments above described indicate that in making tinct. cinchonæ by the process of the Pharmacopœia the bark is deprived of about half of the total alkaloid which it contains.

It is my intention to continue working at this subject in the hope of finding a process for producing a tincture which shall represent the total alkaloid of the bark from which it is prepared. Should I succeed I shall look forward to bringing my results under your notice at a future date.

I cannot conclude without expressing my best thanks to my friend Mr. Wyndham Dunstan for many valuable suggestions, and to Mr. Holmes for kindly identifying the barks.

[*The discussion on this and the following paper is printed at p.* 458.]

THE ALKALOIDAL STRENGTH OF TINCTURA CINCHONÆ FLAVÆ.

BY J. O. BRAITHWAITE.

The difference of opinion which apparently exists as to the alkaloidal strength of the tincture of yellow cinchona and the important bearing that this has on the therapeutic efficacy of a valuable remedial agent, induced me to institute experiments on the matter and to examine commercial samples.

To determine the amount of alkaloid removed by the official process several experiments were made with assayed barks; the "total alkaloids" of both the original bark and of the marc left after making the tincture were estimated by De Vrij's process. The amount of alkaloids in the tinctures was directly estimated by the following process.

One hundred cubic centimetres of the tincture were mixed with 2 grams of freshly slaked lime. This mixture was evaporated to complete dryness and exhausted by boiling with chloroform: when completely exhausted the chloroformic solution was filtered into a small tared flask and the solvent distilled off. The residue dried at 100° C. was weighed as "total alkaloid." For the comparative estimation of the ether-soluble alkaloid, this total alkaloid was digested for twelve hours in a limited quantity of ether (2 c.c. for each 0·1 gram) and the ether evaporated from a tared capsule, the residue being dried at 100° C.

It was found that the mean error of the three estimations, viz., of the bark, the tincture and the marc, did not exceed 0·2 per cent. Thus from a bark yielding 5·224 per cent. of total alkaloid the marc gave 2·665 per cent. and the tincture equivalent to 100 grams of bark 2·359 per cent.

In the above example it will be seen that only 45 per cent. of the alkaloid present in the bark goes into solution. In fact, in poorer barks giving a light coloured tincture this estimate is found to be too high. A sample of tincture may, however, be reasonably expected to contain four-tenths of the total alkaloid of the bark.

The following are the results of the examination of eleven samples of tincture. Nos. 1 to 4 being prepared by myself, the remainder being the commercial article.

No. of Sample.	Total alkaloid.		Ether-soluble alkaloid.		Specific gravity.	Remarks.
	Grams in 100 c.c.	Grains in f℥j.	Grams in 100 c.c.	Grains in f℥j.		
1	0·470	2·05	0·345	1·51	0·9350	Made from a rich commercial quilled calisaya containing 5·224 per cent. total alkaloid and 2·697 ether-soluble alkaloid.
2	0·536	2·34	0·444	1·94	0·8747	Made from the same bark as No. 1, but using rectified spirit instead of proof.
3	0·490	2·14	0·326	1·42	0·9330	Made from commercial calisaya, containing much colouring matter.
4	0·379	1·65	0·161	0·70	0·9256	Made from commercial calisaya, containing 4·392 per cent. total alkaloid, 1·06 per cent. of ether-soluble alkaloid.
5	0·430	1·88	0·254	1·11	0·9289	Trade sample.
6	0·279	1·22	0·078	0·4	0·9374	" "
7	0·350	1·53	0·070	0·3	0·9357	" "
8	0·285	1·24	0·170	0·74	0·939	" "
9	0·417	1·82	0·140	0·61	0·9489	" "
10	0·356	1·55	0·202	0·88	0·9511	" "
11	0·409	1·78	0·204	0·89	0·9346	" "

It will be noticed that in No. 2, where rectified spirit has been used to exhaust, the yield of alkaloid is considerably increased.

Laboratory, 50, *Southwark Street*, S.E.

THE PURGATIVE PRINCIPLE OF CROTON OIL.*

BY HAROLD SENIER,

Fellow of the Institute of Chemistry and of the Chemical Society.

In a paper read before this Society in March, 1878,† I pointed out that English pressed croton oil of undoubted genuineness could be separated by alcohol into two parts. The part soluble in alcohol was, or contained the vesicating principle, while the part insoluble in alcohol was entirely non-vesicating. Further experiments towards the isolation of this vesicating principle I have recorded in another paper. With respect to the other prominent property of croton oil, its purgative activity, I at that time was led by the opinion of therapeutists to believe either that this action was due to the vesicating principle or that it resided in the same portion of the oil—that portion soluble in alcohol; this, however, was not then determined. I now find that the purgative constituent does not exist in the alcohol-soluble vesicating oil, but is entirely in the alcohol non-soluble, non-vesicating oil. This I determined in the first place by experiments on myself and others, and more recently the therapeutic action of this oil has been studied by my friend Dr. J. W. Meek. My experiments consisted first, of the administration of the non-vesicating oil in doses of $\frac{1}{10}$ minim, increased to $\frac{1}{2}$ minim; if this oil contained the whole of the purgative principle, this quantity would be equivalent to about $\frac{1}{5}$ to 1 minim of commercial croton oil. The oil used in these experiments was carefully freed from traces of the vesicating oil by repeated washings with alcohol until nothing more was dissolved. It was administered in the form of pills, and I found magnesium carbonate and extract of hyoscyamus convenient excipients. The general results from these experiments were, briefly, from the smaller doses a mild, and from the larger doses a powerful purgative effect, unaccompanied by any unpleasant symptoms. I supplemented these experiments by the administration of similar doses of the vesicating oil under similiar conditions and obtained no purgative action, but a considerable amount of irritation in the alimentary canal accompanied by nausea.

In conclusion, I do not think I am exaggerating the practical outcome of these experiments when I say, that subject to the results of more extended therapeutic experiments, this non-vesicating croton oil, either in its present form or in the more concentrated form in which I hope to obtain it, furnishes a useful, safe, speedy and pleasant purgative.

Dr. Meek describes the result of the experiments conducted by him as follows:—

Report on the Physiological Action of the Non-vesicating Portion of Croton Oil.

BY JOHN W. MEEK, M.D. LOND.

In order to try the physiological effects of the non-vesicating portion of croton oil, Mr. H. Senier was good enough to supply me with some of that portion of the oil as isolated by him. It was made into the form of pills with extract of hyoscyamus.

Given to healthy adults in doses containing the non-vesicating portion of one-tenth of a minim of ordinary croton oil, beyond slight nausea and some sense of discomfort no appreciable effect was produced; but I found that doses containing the non-vesicating portion of half a minim of croton oil acted as a powerful purgative in from three to six hours from the time of administration. In some of the cases the oil caused griping, but not in all. The motions were usually of a loose character, though not containing a large amount of fluid. The bowels were usually opened two or three times at intervals of an hour or more between each action.

In the doses above mentioned, beyond the action on the alimentary canal, no other physiological effect was observed in any of the cases.

[*The discussion on this and the following paper is printed at p.* 458.]

THE VESICATING PRINCIPLE OF CROTON OIL.*

BY HAROLD SENIER,

Fellow of the Institute of Chemistry and of the Chemical Society.

In a former paper† I gave the results of an investigation into the action of alcohol on croton oil, and found that under certain conditions it separated the oil into two parts; the one part vesicating, the other non-vesicating. I briefly described the vesicating oil and also the non-vesicating oil, which I have since shown to be purgative.

In another paper I have given the results of my work, so far, on this purgative oil. In this paper I show, in the first place, more exactly what the conditions are which affect the solubility of croton oil in alcohol, maintaining and extending my previous conclusions. In the next place, I proceed to determine whether the oil soluble in alcohol is itself the vesicating principle, or what part of it has that power.

The Solubility of Croton Oil in Alcohol.—When alcohol (sp. gr. ·794 to ·800) is mixed in equal volumes with English pressed croton oil, perfect solution takes place, the mixture being permanent at all ordinary temperatures, and this is equally true when any less quantity of alcohol is used. When, however, the proportion of alcohol to croton oil becomes as seven volumes to six, or any larger proportion of alcohol, then a part of the croton oil separates. This part varies in quantity, in the case of different samples of oil, in accordance with the conditions noted in my former paper. It is an interesting fact that that portion of the croton oil which separates when the alcohol is in excess is afterwards insoluble in any proportion of alcohol. But that portion of the oil dissolved by alcohol is, when separated, soluble in all proportions.

In the discussion following my former paper, Professor Redwood remarked on an apparent discrepancy between my results on this point and some experiments made by himself some years previously.

In the experiments reported by Professor Redwood, croton oil and alcohol were used in equal volumes only and found perfectly miscible. This result, so far as it goes, agrees exactly with my own, and no doubt if Professor Redwood had employed other proportions than those given his results would also have coincided with mine. The usual statements regarding the solubility of croton oil in

* Read at an Evening Meeting of the Pharmaceutical Society of Great Britain, December 5, 1883.

† *Pharm. Journ. and Trans.*, March 9, 1878.

alcohol as found in many text-books, and incidentally revived by Mr. A. H. Allen in his recent paper on 'The Chemistry and Examination of Fixed Oils'* are shown by my experiments to be inaccurate.

Search for the Vesicating Principle.—Some of the characters of the alcohol-soluble croton oil, which has been shown to contain the vesicating principle, I have described in the previous paper, to which reference has already been made. The more important of these characters, together with others since observed, are as follows:—At 60° Fahr. this oil is of a brown colour, and holds in suspension a number of acicular crystals soluble on warming. It has a strong characteristic smell of croton oil, a persistent burning taste, and readily produces pustules when applied to the skin. It has an acid reaction and a sp. gr. of ·987.

Solvents were first tried as a means of further separation. Water, alcohol of various strengths, benzol, chloroform, ether, petroleum naphtha, etc., were tried, at different temperatures and in various proportions, but the results did not indicate a method of further separation. The oil was then subjected to distillation, alone, with acids, alkalies, and by the passage through it of heated steam. Several distillates were thus obtained, but they were all non-vesicating. The oil therefore contains no free volatile vesicating principle, neither does the vesicating activity exist in a combined volatile alkaloid or alcohol.

To determine whether the fatty acids or alcoholic radical contained the vesicating principle, the oil was subjected to saponification, first of the free fatty acids. 50 grams of oil were digested on a water-bath for one hour, with 12½ grams of sodium bicarbonate and 10 grams of water. The resulting soapy mass was agitated with petroleum naphtha, and the whole placed on a filter and repeatedly washed with the same solvent. The filtrate containing the unsaponified neutral oil, when evaporated and dried, weighed 38·7 grams; the difference, representing free fatty acids, being 11·3 grams or 22½ per cent. of the alcohol-soluble oil. The soap left on the filter was diffused in hot water and decomposed with sulphuric acid. The free fatty acids which separated in white flocculi were collected and washed, dissolved in alcohol and crystallized. In this state their melting point indicated fairly pure palmitic acid, which was devoid of any vesicating property. The vesicating activity does not, therefore, reside in the free fatty acids.

Returning now to the neutral oil, this was saponified by 10 grams of caustic soda and 20 grams of water. The soap on cooling rose to the top as a hard cake, from which the aqueous solution containing the alcohol radical was easily separated. This on concentration gave no evidence of containing any vesicating principle. The soap was diffused in hot water, decomposed with sulphuric acid, and the free fatty acids separated. The soap previous to decomposition had no tendency to vesicate, but the free acids when liberated were strongly vesicant.

It was now evident that the vesicating principle was among the fatty acids; the next experiments were directed, therefore, to their separation. This has at present been accomplished only in an approximate manner, but the subject presented so many difficulties that it seemed advisable to publish the results so far obtained.

* *Journ. Soc. Chem. Ind.*, February 28, 1883.

Many processes were applied to the separation of these acids, which after much time and careful working gave only negative results. The description of these I shall omit. The following gave the only results from which even general conclusions could be drawn:—First, separation by means of the different congealing points of the glycerides of the fatty acids. Second, separation by means of the different solubilities of their lead salts in alcohol and ether. Third, separation by fractional saponification. Fourth, separation by fractional decomposition of the soda salts. The first of these separations was accomplished by filtration and slight pressure through a plug of tow in a jacketed funnel surrounded by refrigerating mixtures. The manner of accomplishing the other three separations does not require a special description.

The conclusions from the results of these processes were briefly as follows:—First, the vesicating principle is contained in those acids having the lowest melting points. Second, the lead salt is soluble in ether, but not at all, or very slightly, in alcohol. Third, it is contained in those acids least readily saponified by alkalies. Fourth, it is contained in those acids first liberated when the alkali soap is decomposed by acids.

In the next experiment the acids were separated into four groups, as follows:—First, those having ammonia salts insoluble in alcohol (palmitic acid). Second, those (after removal of group 1) which are precipitated from alcoholic solution by magnesium acetate. Third, those which, in the absence of groups 1 and 2, are precipitated as insoluble barium salts in alcoholic solution (oleic, etc.). Fourth, those whose barium salts are soluble in alcohol. The fatty acids were dissolved in alcohol and saturated solutions of the reagents were added. The precipitate in each case was washed on a filter with cold alcohol. The yield of acids in each group was, in round numbers, group 1, 15 per cent; group 2, 20 per cent.; group 3, 40 per cent., and group 4, 25 per cent. of total fatty acids in the neutral alcohol-soluble croton oil. The acids of groups 1, 2 and 3 were entirely inactive as regards vesicating effects, but those separated in group 4 were highly vesicant. These acids when separated are of a dark brown colour, and remain liquid at 50° Fah. They may be further purified by saponification with plumbic oxide, solution of the soap in ether and regeneration with an acid. In this state they are rendered much more active. Taking into consideration the low melting point and the solubilities of the metallic salts, together with the results of the experiments on the separation of the acids by the different congealing points of their glycerides and by their partial saponification, I think it more than probable that this new acid will be found to be closely allied to oleic acid and its analogues ricinoleic and linoleic.

In conclusion, I have shown, first, what the conditions are which obtain in the separation of croton oil by alcohol into its vesicant and purgative parts. Secondly, the vesicating activity of the alcohol-soluble croton oil I have proved not to exist in the free acids and not to belong to any basic constituent, but to reside in the combined non-volatile fatty acids. These have been separated to a considerable extent, if not to complete isolation, and the probable position of the new acid in the fatty acid series I have indicated. The further elucidation and study of the new acid I reserve for a future communication.

NATIONALITY IN SCIENCE.

"All roads lead to Rome," was the old saying, but the individuality of the men who reached the capital was not more distinct and different than the routes they took. Our international courtesies but prove the fact and confirm the observation that the traveller may change his clime, but never his own character.

One would have imagined that this was limited to questions of geography, and that the rule was no longer applicable when it concerned the realms of thought. Yet nothing is more striking than the influence which nationality exerts even in the pursuit of science.

In Rome, the English tourist would be intelligent, brisk in his movements, and observant. In his hands would be found the most approved guide-book and the latest printed information, whether conveyed in story or in a more serious publication; and with restless energy he would try at least to verify the accounts of others.

The Frenchman would skim the surface of society, measure the present and the past by his Parisian experiences, and send home a brilliant and very readable description.

The German would know beforehand every street and bye-path in the city from a caretully studied map, and would be more conversant with such detials than the oldest inhabitant. He would be familar with the theory held by scholars from time immemorial respecting each classic monument.

With some he would agree; while others he would confute; and he would contribute, on his return, a mass of learned disquisitions, invaluable for future reference, though presented with the scantiest arrangement.

We thus gain a key to the sharply defined peculiarities which stamp the productions of the three nations, and probably we must remain content with the results which spring from national sources.

We, as Englishmen, have been accused, though less now than formerly, of following too much in the wake of German original research.

Our distinguished chemists, the moment their home education has been finished, have often betaken themselves to some foreign university where they may be gladdened by the scenery of the Rhine, and may listen to professors who teach more by their own investigations in the laboratory than by an attractive exposition of facts already ascertained.

The Rhineland has hitherto had the monopoly of our best men, and it has sent them back with a deep conviction of the importance of a personal and experimental searching into truth.

There was a time, in the recollection of this generation, when Paris was the centre of attraction. In the fine arts and imaginative literature, the French metropolis still holds its own; and for the written or acted drama has yet no equal.

But the very brilliance of the place, the sparkle of its society, and its unrestful eagerness after pleasure, react upon its men of science.

There are, of course, a few splendid and conspicuous exceptions; but the French investigator aims generally on presenting his work with artistic finish, and in a graceful literary form. Hence, the more serious and matter of fact portion of the community in our unimaginative isle has come to attach a certain distrust to such elegant effusions.

It must be conceded also that French science dates too exclusively from Paris and takes small cognizance of what may be passing elsewhere.

It is, moreover, unfortunate that a national hostility to the German Empire, its people and concerns, is allowed to be an interfering agency in the recognition of that science which, in its very essence is universal.

We may say, without assumption, that the charge justly brought against ourselves of neglect of original research, and of a too ready utilization of other people's labours is daily becoming one that can be less sustained. There is at least an effort and an intention to remove it altogether.

Up to a very recent period we have struggled under considerable disadvantage. Our technical schools, and those adapted to advanced practical work have been few and expensive. There has always been abundance of good elementary teaching, but a scarcity of opportunities furnished for the higher branches and developments of scientific education. Many of our professors are now actively carrying out the principles they have imbibed from continental universities, and stimulate their students to enter on that pathway of research which they themselves are treading. Many others who have never left their home surroundings are doing the same thing. Certain national instincts are in our favour. First, a capacity for generalization which has won fame for our great English men of science; secondly, an absolute freedom of acceptance of all discovery from whatever quarter it may spring; and lastly, the public, now thoroughly awake to the financial and utilitarian value of every description of research, is quite willing to reward substantially those who devote themselves to its pursuits.

LIQUEFIED CARBONIC ACID.

THE fact that carbonic acid gas under a pressure of thirty-six atmospheres and at a temperature of 0° C. passes into the liquid state has been known since the earlier days of FARADAY'S career, but until recently has been turned to little practical account. A few months since, however, some interest was excited by the statement that liquefied carbonic acid was being advantageously used in the manufacture of aerated beverages, and on Monday last, at a meeting of the London Section of the Society of Chemical Industry, the apparatus contrived by Dr. RAYDT, of Hanover, in conjunction with Messrs. KUNHEIM, of Berlin, for facilitating the industrial application of FARADAY'S discovery was explained by Mr. A. ZIMMERMANN. Of course the important part of the problem consisted in providing a vessel capable of holding the acid under the necessary pressure and yet so that it should be available when required. This is effected by constructing a wrought-iron cylinder of about ten litres capacity, representing a quantity of liquid acid which is sufficient when liberated from pressure to yield about 4500 litres of carbonic acid gas of ordinary density. At one end and screwed into the metal of the cylinder is an exactly finished brass screw valve tap, somewhat similar in principle to a high-pressure water tap, by which the exit of the gas can be controlled, so that it may pass into the gasometer or other vessel at any rate desired. It was one of these cylinders that was submitted to the inspection of the meeting referred to, and it was stated that each cylinder is certified to withstand a pressure equal to two hundred and fifty atmospheres. In fact it is claimed that it has been experimentally proved that, with a temperature of 200° C., the enormous pressure of twelve hundred atmospheres can in this way be made applicable.

The brewing industry in Germany has been one of the first to avail itself of the practical advantages resulting from this invention, in using the pressure resulting from the vaporization of the liquid acid for the purpose of raising lager beer from the cask to the place of draught, instead of condensed air pressure, which in some districts is prohibited on account of the usually impure condition of cellar atmosphere. An interesting experiment is also stated to have been made with cloudy beer in an English brewery, when it was shown that instead of keeping the beer in continuous agitation, as was generally expected, the pressure of the liberated gas acted uniformly and steadily on the top of the liquid. In this way, it is affirmed, all the suspended matters to which the cloudiness was due were precipitated by mechanical pressure, the hops floated on the top, and bright beer could be drawn from the intervening space. It is also anticipated that the invention will be utilized by engineers in various ways. Already, in Kiel harbour, a stone, weighing about fifteen tons, has been raised from a depth of thirty-five feet by attaching to it a vessel inflated from one of the cylinders. At Essen, Herr KRUPP is said to take advantage of the pressure obtained by the liberation of the gas to condense the molten iron while cooling in the mould. Further, its use for blasting operations and in locomotive engines has been suggested.

In the early part of last year an imperial decree was issued ordering the adoption in Turkey of the metric system of weights and measures and the abolition of the weights and measures hitherto in use, the names of which were applied to their nearest representatives among their substitutes. Very great difficulty was, however, experienced in enforcing the adoption of this measure, and the obstruction to business proved to be so great that for some time past the Government has been content to ignore the fact that although the new measures are displayed on the counter or carried in the hand, all ordinary dealings are conducted by means of the old ones. It is now reported that another attempt is to be made to give effect to the decree.

* * *

The *Medical Press and Circular* mentions a sad case of poisoning near Greenlaw, Berwickshire, by which a child aged nine months lost its life. It appears that some sleeping powders which had been ordered by a medical man for a Miss Wood were inclosed in a parcel sent to a gentleman who had a married daughter also bearing the name of Wood and who was expecting medicine for her child. Unfortunately when the packet of powders was found it was assumed that they were intended for the infant and one was administered, the consequences being fatal to the child.

* * *

A few days ago an interesting ceremony took place at Liége on the occasion of the opening by the ministers of State of new buildings in connection with the University in that city. One group of buildings erected in the botanic garden is devoted to lecture-rooms, museums, laboratories, herbaria, etc., and another to a museum of economic botany, a library and a physiological laboratory. There was also an institute officially opened which is to be devoted to the study and applications of electricity, and, last but not least, another which is to be devoted to pharmacy.

* * *

At a recent meeting of the Austrian General Pharmaceutical Association, it was decided to reorganize the School of Pharmacy in Vienna, which is henceforth to be known as the School of the Association and of the Vienna Pharmaceutical Gremium. It was stated that the school was attended by thirty male and four female pupils, the latter being nuns.

* * *

The fund that is being raised for the widow and children of the pharmacist's assistant, recently murdered in Strassburg, already exceeds 6000 marks.

* * *

The first sessional meeting of the Manchester Pharmaceutical Association will be held at the Owens College, on Monday evening next, December 10, at 7.30 p.m., when an address to students will be delivered by Mr. W. Elborne, on "The Examinations of the Pharmaceutical Society."

* * *

The next meeting of the Chemists' Assistants' Association will be held on Wednesday, December 12, when a report on "Materia Medica" will be read by Mr. J. O. Braithwaite.

MEETING OF THE COUNCIL.

Wednesday, December 5, 1883.

Present—

MR. MICHAEL CARTEIGHE, PRESIDENT.

MR. SAMUEL RALPH ATKINS, VICE-PRESIDENT.

Messrs. Andrews, Borland, Bottle, Butt, Gostling, Greenish, Hampson, Hills, Radley, Richardson, Robbins, Savage, Schacht, Squire, Symes, Williams, Woolley and Young.

The minutes of the last meeting were read and confirmed.

The late Mr. John Eliot Howard, F.R.S.

The Vice-President moved the following resolution:—

"That this Council learns with much regret the death of Mr. John Eliot Howard, and that the President be requested to write a letter of condolence to Mrs. Howard, expressing the sympathy of the Council with her and the members of her family."

He said it was hardly necessary to say anything in support of this motion, but he felt that not only pharmacists, but the world of science generally, had sustained a great loss in the death of Mr. Howard. He hoped also that he was not going beyond the proper limits in saying that he was much struck by one remark of Mr. Howard when receiving the Hanbury medal at the hands of the President, which showed very clearly the devoutness of his spirit. One often heard of the difficulties of harmonizing faith and science, and he was much impressed with the way in which Mr. Howard avowed his faith in the great principles of the Christian religion.

Mr. Bottle had much pleasure in seconding the motion so admirably moved by the Vice-President. It was not his privilege to know much personally of Mr. Howard, but he had known his name almost as long as he had known his own.

The President heartily endorsed all that had been said by the Vice-President and Mr. Bottle. It would be satisfactory to some of the younger members of the Council, who did not know Mr. Howard personally, to hear that in addition to his other great qualifications he was regarded as a great benefactor by all his neighbours and one of the best counsellors and advisers of his district. The number of persons attending the funeral showed very strongly the great loss which all his neighbours felt they had sustained.

The motion was carried unanimously.

Appointment of Examiners for 1884.

The Council went into committee to consider nominations, and upon resuming the following pharmaceutical chemists were appointed to act as Examiners for the ensuing year, subject to the approval of the Privy Council:—

England and Wales.

Barnes, James Benjamin, 1, Trevor Terrace, Knightsbridge, S.W.
Benger, Frederick Baden, 7, Exchange Street, Manchester.
Brady, Henry Bowman, Hillfield, Gateshead-on-Tyne.
Corder, Octavius, 31, London Street, Norwich.
Ekin, Charles, 2, Lampton Road, Hounslow.
Fletcher, John, Montpellier Avenue, Cheltenham.
Gale, Samuel, 225, Oxford Street, W.
Greenish, Thomas Edward, 5, Bathurst Street, Sussex Square, W.
Linford, John Samuel, 16, Gladstone Street, Hull.
Plowman, Sidney, 2, Residence, St. Thomas's Hospital, S.E.
Southall, William, 17, Bull Street, Birmingham.
Tanner, Alfred Edward, High Cross, Tottenham, N.
Taylor, George Spratt, 13, Queen's Terrace, St. John's Wood, N.W.
Thresh, John Clough, 11, Eagle Parade, Buxton.

Scotland.

Baildon, Henry Bellyse, 73, Princes Street, Edinburgh.
Clark, William Inglis, 26, South Back Canongate, Edinburgh.
Gibson, Adam, Leven.
Gilmour, William, 11, Elm Row, Edinburgh.
Kinninmont, Alexander, 69, South Portland Street, Glasgow.
Maben, Thomas, 5, Oliver Place, Hawick.
Nesbit, John, 162, High Street, Portobello.
Stephenson, John Bertram, 48, North Frederick Street, Edinburgh.

It was resolved—

"That the Board of Examiners for England and Wales shall meet in the months of February, April, June, July, October and December in 1884; and in Scotland in January, April, July and October."

The cordial thanks of the Council were unanimously voted to the Boards of Examiners for their services during the present year.

It was also resolved—

"That this Council desires to record its sense of the value of the services rendered to the Society by Mr. Ainslie as a member for many years of the Board of Examiners for Scotland,"

that gentleman having intimated that he desired to retire from the Board.

A member was restored to his former status in the Society upon payment of the current year's subscription and a fine.

Restoration to the Register.

The name of the following person, who has made the required declarations and paid a fine of one guinea, was restored to the Register of Chemists and Druggists:—

James Alfred Jordan, 113, Every Street, Manchester.

Reports of Committees.

FINANCE.

The report of this Committee was read and adopted, and sundry accounts were ordered to be paid.

BENEVOLENT FUND.

The report of this Committee included a recommendation of the following grants:—

£20 to the widow of a member. Husband was an annuitant for six years, and formerly a member for thirty-seven years (Hampshire).

£10 to the widow of a member from 1841 to 1858. Husband was a surgeon's assistant, suffering from fracture of radius (Middlesex).

£10 to a former member from 1841 to 1881, aged 69. Suffering from heart disease (Warwickshire).

£10 to an associate in business from 1868 to 1877, to aid a fund which is being raised to enable him to emigrate (Surrey).

£10 to the widow of a registered chemist and druggist. Husband in business for many years (Huntingdon).

£5 to the widow of a registered chemist and druggist. Applicant has had three previous grants of £5 each, has to support two children and partly two others (Derbyshire).

£5 to the widow of a registered chemist and druggist. Husband died in January last; was in business in small way for twenty years (Yorkshire).

£5 to the Secretary for his Casual Fund.

The Committee had considered the resolution of the Council that the Benevolent Fund Committee be instructed to undertake the distribution of the proceeds of Mr. Robbins's special donation, and recommended that £5 be given to Henry Edward Davies, a member from 1842 to 1870, who had in former years contributed £13 13s. to the Fund.

Several other applications for assistance, after consideration, had not been further entertained.

The Committee had considered a suggestion made by Mr. Hampson, that persons other than members and subscribers should be allowed to sign petitions for assistance from the Fund, and had decided not to recommend any alteration in the present regulations.

Mr. Hampson said he should like to ask some member of the Committee to state the reasons which had induced it to come to the conclusion that it was inadvisable to make any alteration in the existing regulations in the direction he had suggested. He much regretted that the Committee had not been able to recommend an alteration which would admit of the reception of information from any trustworthy quarter. According to the present rules the Committee could only obtain information from subscribers to the Fund, or from members, or persons connected with the Society or the trade; and he could readily imagine that in small places it might be difficult to obtain the right kind of information; at any rate, he should like to see an alteration by which an applicant would be allowed to have his paper signed by other persons. It was no doubt necessary that some subscriber should attach his name to the paper, but on the other hand, the Committee would often get fuller and better information by going outside the pale of the business. As dispensers of this Fund the members of the Council ought to obtain all possible information, and he was persuaded that the present method was not sufficient, that valuable information was often excluded, and that it was just possible that the Fund might be in that way, to a certain extent, not well administered. He knew it was very difficult to get the right kind of information. The other day he signed a paper, and though he had seen the person occasionally from time to time, he could not feel that he was warranted in signing it from his own information alone. Knowing the pains the Committee had taken, he did not like giving it further trouble; but he still felt that the subject was worth further consideration.

The Vice-President said he had acted as Chairman of the Committee, and he might say that Mr. Hampson's letter was very carefully considered, and if the members of the Committee could have seen their way to adopt the recommendations made, many of them would have been very glad to do so. Amongst the reasons for coming to an adverse conclusion were the following:—It was ascertained from the office that up to the present time there had been no known case of insuperable difficulty, and *à priori* that was an argument against change. He was not quite sure that he apprehended Mr. Hampson's point, because the Committee did accept all the information it was possible to obtain, and in addition to the signatures of subscribers there was generally a mass of correspondence from outsiders which was carefully read and considered. The case which had led Mr. Hampson to write to the Committee was one in which the Committee was informed that there would have been no difficulty in obtaining the requisite number of signatures, and he would remind Mr. Hampson that in respect to small places even there need be no difficulty, because the signatories were not required to be resident in the same place; any member or subscriber resident in a neighbouring town was equally eligible. He should rather put the argument the other way and say that it was very desirable that persons who filled up the official forms should be in the neighbourhood, and if there were a difficulty in obtaining the names, that ought to be a motive for increasing the number of subscribers. Half-a-crown per annum was sufficient to qualify a man, and experience showed that persons were induced to subscribe in order that they might be able to afford assistance to candidates for the charity. If, in any small town where there were four chemists, there were not four subscribers, he thought it would not be difficult to make them subscribe. He believed the Committee was unanimous in thinking that no practical grievance had been shown to exist.

Mr. Savage thought there was a good deal in what Mr. Hampson had said, and he could readily imagine that the office might not always be made acquainted with the difficulties which arose. He could conceive that if there were two chemists in a small town there might be some antagonism between them, and the parties applied to might not readily concur in giving a recommendation. It was generally considered that a clergyman or some official person was much more likely to furnish correct information than someone living in an adjoining place. As an alternative he thought Mr. Hampson's suggestion well worth considering.

Mr. Williams thought the Committee already accepted information from the clergy, or any other resident. It required four subscribers to sign the application paper, but did not limit the information received to those four persons. No doubt it was a troublesome thing to get the paper filled np, and cases might arise in which the Committee was not able to give relief on this ground alone, though the case was a deserving one. At the same time the argument adduced that anyone could become a subscriber by paying half-a-crown was very strong.

The President, referring to the rules, said that section 8 provided that the application must be signed by four persons who had subscribed not less than half-a-guinea for three preceding years, or had given a donation of five guineas. In the case of widows and orphans, the Council was allowed to receive the testimony of four persons who had subscribed half-a-guinea for the current year. On the face of it the regulation appeared a little hard.

Mr. Richardson had considerable sympathy with Mr. Hampson's proposition, and thought it might prove a hardship in small towns that some other source of information was not available. He thought the evidence of a minister of religion would be the best obtainable. In some cases there was a considerable amount of diffidence, and these were just the cases which were often the most deserving. It was very desirable that some means should be adopted by which every deserving case could be reached.

Mr. Andrews supported Mr. Hampson's view. It was within his knowledge that difficulties had occurred in getting the paper signed. In one case he felt that he did not know so much about the person as he should have liked, and there was great difficulty in getting the fourth name. It would be a step in the right direction if all applicants were put on the same footing as widows and orphans.

The President said there seemed to be two questions involved; one, whether it was expedient to insist on as many as four subscribers signing the first certificate; and secondly, as to subsequent information, with regard to which he understood there was practically no limit. He understood Mr. Hampson to advocate allowing any responsible person to put the machinery in motion for inquiry. That he understood had been considered by the Committee, who thought it would not be to the interest of the Fund to leave the power of signing quite so open.

The Vice-President said there might be something to be said in favour of reducing the number of signatories required, and that point he thought the Committee would be willing to reconsider; but the logical conclusion from Mr. Hampson's remarks would be to dismiss the necessity of having any subscribers at all.

Mr. Robbins thought it might be desirable to have a change. It was frequently found in the case of widows and orphans that there was great difficulty in finding subscribers who could speak from personal knowledge of them, though they might have known the husband very well. If the applicants were known to a clergyman or a justice of the peace that should be sufficient; but he should be sorry to see a change with regard to the male adults, because he thought if they were not known to four members of the trade they ought not to receive assistance. He thought that any man who had been in business would be known by the chemists in another town a few miles off, and would have no difficulty in getting his paper signed. If the Committee went outside and did not limit the recommendation to clergymen and justices of the peace it would know as little about the person signing the paper as about the applicant himself. All the members knew Mr. Hampson, but if they had a paper signed by a Mr. Jones, grocer, Islington, they would have to make inquiries to know whether his recommendation could be accepted. Anyone applying for the benefit of this Fund ought to be known by his brother tradesmen, and in making grants great importance was attached to the names appended to the papers. Mr. Hampson must know that information did frequently come in from outside sources, and several instances might be named in which that outside information had been the means of securing the grant. He remembered several cases in which the Committee had received information from medical men who had attended applicants.

The Vice-President remarked that the Committee had had a good deal of outside evidence before it in dealing with applications for assistance on the previous day.

Mr. Radley said there were several new points now suggested which might be worth consideration by the Committee, but he was satisfied that in the main the principle hitherto acted upon was correct.

Mr. Young said he was not present at the Committee meetings, but he felt rather favourably disposed towards Mr. Hampson's suggestion; perhaps the name of a clergyman or justice and two subscribers might be sufficient. Even then there might be a difficulty in finding two persons who knew the applicant personally, who had subscribed for the specified time; but if the 8th section were altered in accordance with the 9th that difficulty would be overcome, because persons did not generally get into destitute circumstances all at once, and they might prepare for what was coming by getting two friends to subscribe 10*s.* 6*d.* each for a year.

Mr. Symes thought that there was certainly something to be said in favour of a modification of Mr. Hampson's suggestion. He had seen something of the working of the regulations and only remembered one case in which there was great difficulty, where a widow in advanced years could scarcely remember the names of persons who had known her husband in former times. If there had been only two names required, the thing would have been exceedingly simple. If there were an alternative, either four subscribers, as at present, or two subscribers and a clergyman or justice, so long as two subscribers at least were retained, he thought the difficulty would be got over. Or it might be accomplished by reducing the number of years for which a person should have subscribed. The difficulty did not lie in getting signatures, but in ensuring that they were signed by trustworthy persons, on whose judgment the Committee could rely. Many persons could sign papers but could not give satisfactory answers from personal knowledge to the inquiries made by the Committee. He had signed a paper for a person he had only known for about two years, but he did not do so without making numerous inquiries. If he had had to depend upon his personal knowledge he could not have signed it.

Mr. Schacht said it seemed to be thought desirable that each one should express his sentiments on this not very important matter—it did not seem very important, because he had not heard any very large number of grievances in connection with the history of the Benevolent Fund, and, therefore, *à priori* one would rather that things were left in their present condition. Supposing any difficulty arose he thought the suggestion of Mr. Hampson was not a fortunate one, because it seemed to him rather incongruous that Mr. A., who had nothing to do with the Fund, should recommend Mr. B. to give somebody else something. The people who had a right to give money were those who gave out of their own pocket, not those who gave it out of somebody else's pocket. Therefore, it seemed to him that if there were any difficulty, and it might be that, occasionally, difficulties arose, Mr. Hampson's suggestion would not be likely to commend itself. It seemed to him that the recommendation of the grants ought to come from those who found the money.

Mr. Squire said a remark had been made by the Vice-President that it would be perfectly easy for anybody to sign a paper, as he had simply to pay half-a-guinea, but, as a matter of fact, he would have to pay half-a-guinea for three years previously, and, therefore, it was quite impossible for a man even on a month's notice to make himself eligible to sign a paper.

The Vice-President said he must admit that he had been misinformed as to the amount of subscription which would qualify a person to sign, and it did give some point to Mr. Hampson's contention. It was not brought before the Committee on the previous day, and he thought it might be wise to refer the matter again. There was a great deal of force in what Mr. Schacht said, and he certainly would not allow the recommendation to be entirely outside the hands of subscribing members. He must repeat that he did not know of his own knowledge of a single case of hardship having occurred.

Mr. Borland said in looking over the list of contributors to the Benevolent Fund in various small places he found there were very few who contributed to the amount of half-a-guinea, and that rendered the difficulty of finding signatures to these papers still greater. A great many were subscribers to the extent of five shillings, and if the report was sent back to the Committee he thought it might well take into consideration the propriety of reducing the qualifying amount, and leaving out the period of three years. He did not believe the Fund would suffer in the least from such a change, but on the other hand, it would give a greater number an interest in the matter, and would tend very largely to an increase in the income.

The Vice-President said he would move that this portion of the report be referred back to the Committee.

Mr. Bottle seconded this suggestion. He rather supported Mr. Borland's view that the amount required to entitle a contributor to give a recommendation should be reduced from 10*s.* 6*d.* to 5*s.*. He did not like reducing the number from four to two. There was another view of the matter to be taken, and that was the interest of the Benevolent Fund itself. In all societies where there was a benevolent fund it was fenced round about with a certain amount of preliminary introduction, which involved the necessity of advertising the fund and making it known.

Mr. Hampson said he feared he had not been sufficiently explicit in his remarks, but in his letter to the Committee, he simply asked for the consideration of some alternative method of receiving signatures of persons other than chemists. He had not heard anything which had at all shaken his view that the present method was not exactly the best. He did not wish all the signatures to be other than chemists', but if they were combined with one outsider he thought it would be in some respects beneficial.

It was then resolved that the report and recommendations be received and adopted, with the exception of the paragraph having reference to the regulations of the Fund, and that this question be remitted to the Committee for further consideration and report.

Amount of Subscriptions in 1883.

Mr. RICHARDSON asked if the Secretary could give any information as to the amount of subscriptions received this year as compared with last year.

The SECRETARY, after making inquiries, reported that the subscriptions received up to the present time for this year were £1520 3*s.* 8*d.* Last year to the end of December, they were £1568, so that they were nearly the same. With regard to donations; last year they were £388 1*s.*, and the present year, only £94 15*s.* Last year there was £300 in legacies and this year up to the present time none had been received. On the whole, therefore, the Fund had received this year £642 less than last year.

Publication of List of Subscriptions.

Mr. SYMES moved, and it was seconded by Mr. RADLEY, and carried unanimously, that the list of subscriptions to the Benevolent Fund be published in the *Pharmaceutical Journal* of February 23 next, and that a copy be sent to every chemist and druggist on the Register.

The Secretary reported that Mr. Matterson of Dewsbury had sent a donation of twenty guineas to the Fund, in addition to a previous donation, and stated in his letter that he considered this the finest charitable institution he knew of.

LIBRARY, MUSEUM, LABORATORY, AND HOUSE.

Library.

The report of the Librarian had been received, including the following particulars:—

Attendance.		Total.	Highest.	Lowest.	Average.
October.	Day	527	31	7	19
	Evening	206	19	4	9

Circulation of books.	No. of Entries. Town.	Country.	Total.
October	204	144	348

Carriage paid, £2 5*s.* 4½*d.*

The undermentioned donations to the Library had been received, and the Committee recommended that the usual letter of thanks be sent to the respective donors:—

Brighton Health Congress, 1881, Transactions.
From Mr. J. E. MAYALL.

Swiezawski (E. S.) i K. Wenda, Materyjaly do dziejów farmacyi w dawnej Polsce, *etc.*, 1882–83.
From M. WENDA.

Meyer (A.), Ueber Psychotria Ipecacuanha, 1883.
From the AUTHOR.

Newman (D.), On Malpositions of the Kidney, 1883.
From the AUTHOR.

The Committee recommended the purchase of the undermentioned books:—

Smith (E.), Foods, latest ed.

Laborde (J. V.) et H. Duquesnel, Des Aconits et de l'Aconitine, 1883.

Candolle (Alph. de), Nouvelles Remarques sur la Nomenclature Botanique, 1883.

Prantl (K.), Lehrbuch der Botanik, 5e Aufl., 1883.

Watts (H.), Manual of Chemistry, vol. i., 1883.

Lancet. A second copy.

Curator's Report.

The Curator had reported the attendance in the Museum during October to have been:—

	Total.	Highest.	Lowest.	Average.
Morning	516	28	13	19
Evening	116	15	1	5

The following donations to the Museum had been received, and the Committee recommended that the usual letter of thanks be sent to the respective donors:—

A specimen of Benzoic Acid prepared from Hippuric Acid, and a specimen of the same prepared by sublimation. From Mr. J. T. DYMOND.

Specimen of Jamaica Jalap.
From Messrs. WRIGHT, LAYMAN and UMNEY.

Specimens of Menthol in fine crystals, and of Ceylon Gamboge in the tear.
From Messrs. HEARON, SQUIRE and FRANCIS.

Specimen of *Tachia Guianensis.*
From Messrs. SYMES and HALLAWELL.

Very fine specimens of different varieties of Ginseng Root. From Messrs. WILSON and Co., Shanghai. These specimens were brought home by Dr. V. KNAGGS.

Specimens of very fine Brazilian Ipecacuanha Root; Specimens of *Pao Pereiro* Bark, of the Roots of *Smilax Japecanga*, *Anchietea salutaris.*, *Solanum Jequirioba*, and of the leaves of *Ipeuva*, *Pipi Guiné* and *Solanum Jurubeba.*
From Messrs. T. CHRISTY and Co.

Very fine specimens of Cuprea Bark, *Cinchona succirubra* from St. Helena, Ball Tobacco from Zambesi, and the fruit of *Strychnos spinosa*; Specimen of the Oil of *Perilla ocymoides*, of Refined Cotton Seed Oil, and Herbarium specimens of the Cotton Tree.
From the DIRECTOR, Royal Gardens, Kew.

Specimens of Batoum Tea, of *Kabuklu jeviz*, *Kara Halileh*, and Kakulla Cardamoms.
From Mr. C. B. ALLEN.

The practicability of exhibiting new forms of apparatus in the Society's Museum had been considered, and the Committee was of opinion that, having regard to the limited space available in the Society's house, it was not practicable at present to devote any of the cases to this purpose.

It was also recommended that the present assistant to the Curator be engaged at a salary of 30*s.* weekly.

Estimates for printing the Register and Calendar had been submitted and approved, and it was recommended that 1600 copies of the Register and 900 of the Calendar be ordered.

A letter from the Secretary of the College of Preceptors had been submitted to the Committee stating that in consequence of the increase of time occupied by the Preliminary examination, which would involve more work for the Examiners, the fee payable to the College would have to be increased by about 30 per cent. It was recommended that this increase be allowed.

The adoption of the report and recommendations was moved by Mr. ROBBINS and seconded by Mr. GREENISH.

Mr. SYMES said he was sorry to hear the Committee had reported that it could find no room for what he considered to be a portion of the educational usefulness of the establishment. On more than one occasion he had urged the desirability of exhibiting forms of improved apparatus, and he could only say that he should move a resolution that space be acquired for the purpose. He believed that was as important as any part of the educational work there, and that there should be no space in which the things could be deposited was very unfortunate. He had hoped that some such place would have been found available. Some time ago he read a paper on Filtration, at Liverpool, when he suggested a particular form of funnel which he had seen somewhere in Paris—he had forgotten where. However, he succeeded in getting one, which he had brought up with him and intended placing on the table that evening. There might be persons present who would be interested in the matter, or there might not; but it would no doubt be reported in the Journal, and the result would be in the ordinary course of things that he should get a number of letters asking where this funnel could be obtained. It would be much more satisfactory if all those persons could know that if they came to that institution they could see such things and judge for themselves whether they would be useful. He had intended to leave it there for some time, but he now found that there was no place where a funnel holding half a pint could be put. Knowing the trouble and time spent by the Committee in doing its work, it was painful for him to disagree with any portion of their report, but he should feel it a matter of duty to the members generally to vote against that portion of the report.

Mr. Hampson said he was not able to attend the meeting of the Committee referred to, but he thought it was somewhat unfortunate that there was no place in which to deposit a few pieces of apparatus which would be interesting to chemists. It was a melancholy admission to make, but it might be that it was desirable to make it, because if small apparatus were brought in, possibly large apparatus would be; but he could not help thinking that some place ought to be found for the purpose of depositing apparatus of a simple character which might be useful and interesting to the members. What was the Society for? Not simply that there should be a Museum for showing chemicals and drugs. Surely the means by which the chemicals and preparations were made were as important as the drugs themselves. Therefore, though he did not like to vote in the teeth of the Committee's report, he thought this subject was worthy of reconsideration.

The President said the subject presented itself in several aspects. He did not think the report would apply to the case presented by Mr. Symes, but the Committee understood the proposal to be that novelties in apparatus should be exhibited, not temporarily but continuously. That was the question considered, and the answer was that it could not be done, the room in the house being wanted for other purposes, and at present it appeared to the Committee that this space had better not be interfered with. To show that the tendency of the Committee and the officers was in the direction advocated by Mr. Symes, it would be remembered that they had already suggested a little alteration in connection with the Evening Meetings, namely, that the meeting should begin at half-past seven, and that persons should be invited to send apparatus and leave it there for an hour before the business commenced, so that those interested might come and examine it. He did not think it would be necessary to pass any formal resolution to carry out what Mr. Symes required as regarded his funnel, but the question of exhibiting novelties and apparatus in these days of advancing chemistry was a very large one, and the Committee was unanimous in thinking that until the Society got the next house or some large place it could not be done satisfactorily. The Curator could take charge of small things for a certain time, but the continuous exhibition of novelties in apparatus could not be kept up in a way that would be thought satisfactory.

Mr. Savage thought the suggestion of the President a very good one as far as it went, but to his mind it did not go far enough. The number of persons who would see this apparatus at an Evening Meeting was comparatively small, and he thought it might be arranged with regard to any small apparatus, such as would be exhibited at the Evening Meetings, that it might remain for some time, so that it might be seen by other members.

The President said the Committee was very desirous that the Society's premises should be made useful to all the members. The question had been considered all round, and, as was known, novelties in materia medica and chemistry were already arranged for; but with regard to apparatus, the question of space was so very pressing that at the present time the Committee could not see its way to doing what was desired.

The Vice-President said the subject was considered with all desire to meet Mr. Symes's wishes if possible; but the Committee did not find it practicable. The question would arise, which had arisen already with regard to the national collection very close by, a large portion of which had had to be removed to South Kensington. There was not space enough in that house, and where was the line to be drawn? Between a half-pint funnel and a large soda water machine there was an enormous variety, and who was to draw the line?

Mr. Symes said he should move that the report of the Library, Museum, Laboratory and House Committee be received and adopted except that portion which refers to the space for new and improved forms of pharmaceutical and chemical apparatus, which portion be referred back to it for further consideration. In answer to the arguments which had been made use of, he would say that the Committee would certainly not pass the resolution without having the control over the things sent. He had never suggested that soda water apparatus should be sent; he did not know whether it would come within the designation of pharmaceutical or chemical apparatus. If he were on the Committee, and someone sent in a soda water machine which had a great deal of interest for pharmacists, he should inform him that there was not space to exhibit it, but if he would send a small model room would be found for it. Regulations might be made that apparatus exceeding certain dimensions could only be exhibited in model. They were told that space would be required equal to South Kensington Museum. He could only say that taking the last ten or twenty years, all improved apparatus necessary to be shown could have been put on that Council table, either in reality or in model—at any rate it could be very conveniently put in half the room. It would not be difficult to find space as time went on. He thought the importance of this subject was very largely under-estimated. When chemists read of anything interesting at an Evening Meeting they made a note of it and would go to the Society, and they would much rather come and see an improved form of apparatus than the whole of the present Museum. There was no case in the Museum which would be so likely to attract the average pharmacist to the institution as a case in which he could see the improved means by which he could manipulate the materials and carry on his business. To all men it was an important matter to know how to carry on their business with the greatest facility. He did not wish this especially for country members, because he occasionally went round in London, and he found some of the London men were quite as backward as those in the country and quite as amenable to improvement. It would be useful to all to know that they could come there and look at new things, and that would be an inducement to all to look to that institution as a central point from which they might gain information in all forms. Things of that sort would be far more useful than the fine specimens of drugs and chemicals which were to be seen in the Museum, which were not always of the character of those from which chemists had to select in making their ordinary purchases.

Mr. Williams asked if all the splendid samples were to be turned out of the Museum to make room for pieces of apparatus from all parts of the Continent and America. It seemed to him the thing was absurd.

Mr. Hampson said he felt bound to second the amendment of Mr. Symes, although he had always worked harmoniously with the Committee.

The Vice-President said he did not make the absurd remark that a place would be required as large as South Kensington Museum. He simply gave the illustration that some of the treasures of the British Museum had had to be removed to South Kensington for want of room.

Mr. Richardson said this question had been discussed for two or three years, and he thought it was hardly fair for Mr. Symes to impeach his brother councillors in the way he had that morning. No one was more anxious than he was that an exhibition should be held, if it were practicable, for their country friends, but they had had two exhibitions which had been failures.

The President said it was not a question of an exhibition, but a permanent collection of novelties.

Mr. Richardson said he had no doubt that would be carried out when the Committee could see its way clearly as to space and other matters. To his mind there was not such an immense number of new inventions, unless they took into consideration the enterprise of their brethren across the Atlantic, who were very profuse in the development of apparatus of every description.

Mr. Squire said he must challenge one statement which had been made. It was a question of space, and if it were true that that table would hold all the new and improved apparatus required it might not be such a great difficulty, but the question raised by Mr. Symes was a particular sort of funnel for filtration, and he should say that if they simply exhibited the different forms of apparatus for filtration alone, let alone anything else, it would occupy far more than the space stated. Filter presses, very good in their way and distinctly pharmaceutical, had been exhibited in those rooms; but if a filter press sent by one maker were shown all the other makers would at once want to exhibit theirs. There were various ways of filtering, as filtration by pressure and by vacuum, and he was quite certain that the Council table would not hold the different forms of apparatus used in that one process—in fact the house itself would not hold the different forms of apparatus.

Mr. Bottle said he was much surprised to hear from Mr. Symes that he had any doubt about whether soda water apparatus came within the scope of pharmaceutical or chemical apparatus, because when soda water had found its way into the Pharmacopœia there need hardly be any misgivings as to whether the apparatus would come within the definition. He thought Mr. Symes had adopted the proper course in introducing the funnel to the Evening Meeting; and all similar small portable things might be shown in the same way, and then, at the discretion of the President or the Evening Meetings Committee, they might remain within the building for a few weeks or months, available for the inspection of those interested in coming to see them. He did see, however, a great difficulty in opening the door to large apparatus, and could not tell where the line could be drawn.

The President then put the amendment, and Mr. Symes requested that the names should be taken. The following was the result:—

For—Messrs. Andrews, Hampson, Radley, Savage, Symes and Woolley. 6.

Against—Messrs. Atkins, Borland, Bottle, Butt, Carteighe, Gostling, Greenish, Hills, Robbins, Schacht, Squire, Williams and Young. 13.

Mr. Richardson was present at the division, but did not vote.

The amendment was therefore lost, and the original motion was then put and carried.

Mr. Greenish said he wished to suggest that whenever there was a division the names of the members voting on each side should always be taken. He had been waiting for some time for an opportunity to bring this matter forward, because some subjects came before the Council which were popular but not very important, and others which were important but might not be very popular, and when a member rose on certain occasions only to require that the names be taken it gave an air of fictitious importance to the question which would not otherwise belong to it. He would propose, therefore, that in all cases where there was a division the names should be taken.

Mr. Schacht said he was of the same opinion, and when a resolution of this kind was proposed he should be glad to support it.

GENERAL PURPOSES.

The report of this Committee included the usual letter from the Solicitor, giving particulars of the progress made with the cases placed in his hands. It stated that—

Alexander Holmes, 40, High St., Stockton-on-Tees, trading under the name of "The Northern Counties Supply Stores," had, prior to the date fixed for the hearing of the case, remitted the penalty sued for and court costs.

Several cases of alleged infringements of the Pharmacy Act had been before the Committee, with regard to which further inquires were directed to be made.

The report was, as usual, considered in committee.

On resuming, the report and recommendations were unanimously adopted.

Pharmacy Acts Amendment Bill.

The Secretary read a communication from the Lincolnshire Association for the Prevention of the Administration of Poisonous Drugs to Horses, enclosing resolutions passed by the Association at its annual meeting on November 9, thanking the Council for the steps it had already taken with regard to preventing the sale of poisons, urging it to press on the Amended Bill by every means, and saying that the members of the Association were of opinion that it was of the utmost importance that hellebore and salts of copper should be included in the schedule. The Secretary of the Association had also informed him that a communication had been received from the Privy Council on November 7, stating that the subject of the amendment of the law respecting the sale of poisons was still under the consideration of Her Majesty's Government.

Mr. Hampson inquired if the President had any information to add to that contained in the letters just read. It was quite time the Council should know what were the intentions of the Government with respect to the amendment of the Pharmacy Act. There were instances of infringement constantly occurring. Small companies were being established for the purpose of evading the Act, and the whole thing was so unsatisfactory and so dangerous to the interests of the public that it was quite time that either the Council or the Government should take steps to remedy the evil. He should be glad to know if the President had received any communication from the Privy Council which would make it clear that it was intended to amend the law. If not it would be the duty of the Society to take the initiative and find some independent member who would introduce the Bill. The State had interfered with the dealers in drugs by legislation which was imperfect, and the Society was bound not only in the interest of the public, but in the interests of chemists and druggists, to see that the law was not allowed to become a dead letter.

The President said he was sorry to say that he could not give any further information at present. He had made use of the communication just read to go down to the Privy Council, where he was informed that the only answer that could be given to him, either privately or publicly, would be that the matter was still under the consideration of the Government; that the Government was anxious to do something, and hoped in the course of this or next month to have a clear idea on the subject. He could only say that he had put these matters prominently before the department as requiring attention and a definite reply at the earliest possible moment.

Mr. Hampson suggested that it would be well for the Committee to meet at an early date to confer with the President on the subject. Time was pressing. Parliament would meet in February, and it was probable that the Government was already arranging as to what Bills should be introduced.

The President said he should certainly summon the Committee at an early date.

Mr. Bottle thought with Mr. Hampson that it was most desirable to learn at an early date what the views of the Government with regard to the amended Pharmacy Bill were. If the Government had no intention of introducing a Bill next session it would be the duty of the Council to introduce one independently. There was no doubt, as everyone saw day by day, that the present Acts were being evaded and driven through in all directions. Whether the Government would see fit to assist in mending that condition of things was for it to decide, but the Council had a good case to lay before Parliament, and there was a little interest now stirred up in the country which would help in promoting, and probably in securing, the passing of a measure. He would suggest that steps should at once be taken in this direction, and if the President would endeavour to get some information, and summon the Committee, it would be a good thing.

Mr. Schacht said so much would depend on the position the President could take in his possible interviews with the heads of the department that he should rather like to know the view of the Council as to the direction in which it was possible that pressure might be judiciously exercised. It had been to him for a long time extremely disagreeable to have to vote for legal proceedings being taken against poor creatures who perhaps had offended against the law; who, it appeared to him, were sometimes as well able to conduct their business as he was, but who had not exactly complied with the letter of the law. It had been painful to him to be compelled to vote for legal prosecutions and taking steps in such cases, whilst at the same time he was aware that flagrant and absolutely violent hostility to the principle of the Act was being carried into practical effect by persons who just managed to evade, according to recent decisions, the letter of the law. The Council had lately been considering the case of an unfortunate individual, about whom there was some doubt as to his being legally entitled to practise, and the officers were actually taking a vast deal of pains to ascertain whether two or three gentlemen who had declared that he was right in practising were telling the absolute truth or not, and at the same time they had been informed, within twenty-four hours, that an individual whom the Council had threatened to prosecute the other day had put himself within the letter of the law by making his concern a limited liability company, and who was publicly advertising that he was defying the Act of Parliament. Could not the Council ask the President to go armed with this kind of argument? When he next found himself face to face with the Government officials, could he not urge with something like force that it was almost impossible for a body of men, constituted as that Council was, to carry out the existing Act of Parliament against petty paltry offenders, who were scarcely worth powder and shot, and who were scarcely doing any harm in the localities in which they were practising, whilst at the same time courts of law declared that they could not touch the most flagrant and successful attempts to evade the Act? Could he not say that this was a position in which no responsible body ought to be placed, and that if it could not be altered the Society should be free from the responsibility of carrying out the Act? He had used that argument himself with his own members, and if the President had the chance of using some such argument to the head of the department it ought to carry some force with it. It was a painful position to be put in to have to tread into the dirt the poor little worms in the way, whilst the bold creature in the forest, who was really the mischief-maker, was allowed to escape with impunity.

Mr. Symes said the recent action which had been taken to make the position known to members of Parliament would certainly assist at the present time; but if the Bill were delayed for another session a great deal of that effect would be lost.

The President said he would call the Committee together as soon as possible, and would endeavour to obtain some further information.

The School of Pharmacy Students' Association.

The President said an amended set of bye-laws for this Association had been submitted for the approval of the Council according to the regulations. He had read through the rules, which seemed to be all reasonable and proper rules, and he would ask the Council to approve of them.

Mr. Hills asked what was the principal alteration.

The President said the principal alteration was simply verbal, to allow the admission, as members of the Association, of any student, past or present, of the School of Pharmacy of the Society.

The rules were accordingly approved.

Preliminary Examination.

Mr. Woolley asked what steps it was necessary to take in order to place the name of the Victoria University, of Manchester, on the list of educational bodies whose certificates would be received in lieu of the Preliminary examination.

The President said that formal application must be made to the Board of Examiners, who passed it on to the Council.

EVENING MEETING.

MR. MICHAEL CARTEIGHE, PRESIDENT, IN THE CHAIR.

The third Evening Meeting of the session was held on Wednesday, the 5th inst., at half-past eight o'clock.

The minutes of the last meeting having been read and confirmed, two papers were read entitled—

Notes and Suggestions upon Tincture of Nux-vomica; and

On Extract of Nux-vomica.

BY WYNDHAM R. DUNSTAN AND F. W. SHORT.

The papers are printed on pp. 441 and 443, and gave rise to the following discussion:—

Mr. Umney said there could be no question as to the great importance of the subject, both to the medical practitioner as well as to the pharmacist, for such a variation in the proportion of strychnia in the extract as the authors had pointed out was a very serious matter. He was inclined to think that the alkaloidal difference in the extract arose more from the fact that the strychnos seeds themselves differed, rather than from the mode of manufacture. The manufacture of strychnia in England was confined to one or two firms only; the custom of buyers was to refuse strychnos coming from Calcutta or Madras, and select that which came from Calicut. He imagined that they had found that the latter yielded a larger percentage of alkaloid than the others. He was looking forward to enlightenment from the authors upon this point, for he did not know any book in which the percentage yield of these alkaloids was recorded in the same way as the different percentages of alkaloids yielded by cinchona barks were mentioned. As to the abstraction of the oil, he was not at all sure that such was practised. Speaking for himself, he invariably operated on large quantities of nux-vomica for the sake of convenience, and he had generally used a spirit about 63 degrees over proof, containing say 90 per cent. of alcohol. So far as the removal of the oil from the extract was concerned, he did not think that that would be carried out by any manufacturers in an extract so produced. His own notion was that proof spirit would be the most suitable solvent. Certainly it would act less upon the oil; and if it extracted both the strychnia and the brucia and other extractives equally well as rectified spirit and the latter not in excess, he did not see any reason why it should not be far preferable to alcohol of 85 to 90 per cent.

Mr. Brownen would like to ask the authors whether their attention had been called to a solid extract which, about a year or two ago, was in the market, and which was prepared by means of acid and water. He believed that the acid was acetic. The extract was exhibited in the form of dry chocolate coloured masses. It might be that acetic acid in a dilute form, similar to that used in the preparation of the extractum colchici aceticum, might be of advantage in the extraction of nux-vomica.

Dr. Symes said that in a discussion which took place at the Pharmaceutical Conference on a paper on this subject by Messrs. Dunstan and Short, Mr. Conroy, Liverpool, suggested that possibly the higher strength of certain liquids was due to the fact that they had been extracted with a weaker spirit, because it was found that all the tinctures of higher specific gravity contained more alkaloid. At the last meeting of the Liverpool Chemists' Association, Mr. Conroy had read a paper on the subject, in which he recorded experimental results that agreed pretty well with those obtained by the authors of the present paper.* He (Dr. Symes) would suggest that the authors, in pursuing this subject, should ascertain whether proof spirit removed the alkaloid from the oil; that is to say, whether it separated a certain amount of oil which was bitter, and which gave evidence of containing some alkaloid which, possibly, was present as free alkaloid and not as a salt. If that was the case it would be interesting to ascertain whether the proof spirit or the mixture of 100 parts of rectified spirit and 25 parts of water, as recommended by the authors, really washed out the alkaloid from the oil. If it did not do so, that fact certainly went against using the weaker spirit. An extract was, however, much more elegant when prepared without the presence of much oil. Speaking of tincture of nux-vomica, the authors mentioned that the amount of alcohol which they used did not exhaust the nux-vomica, as the marc in each case was bitter. It had occurred to him that as the process was one of maceration, of course the marc as left would be still saturated with the tincture, and to ascertain whether the tincture was capable of exhausting it, it would be necessary to try some further experiments. One would fancy that the quantity of spirit which they used was capable of exhausting it, and, in fact, in the case of the extract it did appear to be sufficient. Mr. Conroy, since writing his paper, had operated on three quantities of the same nux vomica, namely, 100 ounces of each. With rectified spirit he obtained 8½ ounces of extract. With a mixture of equal parts of rectified and proof spirit he got 10½ ounces of extract, and when he used proof spirit he got 11½ ounces. As a larger percentage of extract was obtained by using the weaker spirit, it was necessary, of course, in examining the extract for alkaloid to recognize the fact that a larger percentage of extract had been obtained. The appearance and character of these extracts indicated that the oil was no advantage. The presence of the oil made the extract more difficult to combine, and it formed a very tenacious and unsatisfactory substance to work into a pill mass. He was glad that the authors were giving their attention to the question of uniformity of strength in tincture of nux-vomica. He had known as much as a drachm dose of the tincture prescribed, and the variation in the strength which had been indicated would be a very serious matter.

Mr. Giles said that very many years ago he suspected the judiciousness of the strength of the spirit employed in making tincture of nux-vomica especially, and he was led to the conclusion that a weaker spirit was more effectual. He was glad to hear his opinion substantiated by the present paper. As he had said on former occasions, he thought that the whole question of the alcoholic strength of tinctures wanted revision. There appeared to have been a kind of superstition that there was something magical in the conditions of rectified and proof spirit. He was sorry that this subject had not been taken up by pharmacists in England before being apparently nearly worked out in the United States. After all, that which he regarded as the most important feature of the paper was the question of standardizing preparations. When they were dealing with such potential agents as nux-vomica in the forms of extract and of tincture, it was perfectly absurd that they should be absolutely ignorant of their relative strength. He thought that pharmacists had been a little too much the slaves of the Pharmacopœia. When a preparation got into the Pharmacopœia it appeared to be felt that nobody had a right to interfere with its essentials, and that all that pharmacists could venture to do was to endeavour to carry out the instructions of the Pharmacopœia in the most convenient way. Hence pharmaceutical research was stifled, and was not allowed to exercise itself as it ought to do. The reason evidently was that they had no chance of dealing with the Pharmacopœia. They were not the makers of the Pharmacopœia and he was not clear that they were fit to be the makers of it, but he was quite sure that nobody else was so fit. Inasmuch as the Pharmaceutical Society and pharmacists did not appear to be able to get their claims recognized, he would suggest that they should constitute themselves a Pharmacopœia Committee, and that they should raise a fund with which to endow a pharmacopœia laboratory. The notion of producing a pharmacopœia appeared to be, to slumber for ten years and then to wake up and say, "Let us make a pharmacopœia;" whereas the work was one which should be going on incessantly from day to day. He regarded it as worthy of the consideration of the members of the Society to take a new departure and put themselves into such a position that no body thenceforward should attempt to touch the Pharmacopœia without coming to the Society and receiving the benefit of those stores of information which it had accumulated.

Mr. Greenish said that, as pharmacists, they had been alive to the question of the strength of spirit used in making tinctures. On one occasion during the Presidency of the late Mr. Haselden, he (Mr. Greenish) had read a paper on this subject and had suggested that pharmacists would do well to turn their attention to the Homœopathic Pharmacopœia, where the relative proportions of spirit and water were suited to the various ingredients.

Mr. Dunstan, in reply, said that with reference to the origin of the seeds, Mr. Short and he had started an investigation upon that point, but it was somewhat difficult because there were no good specimens to be obtained in England, and the work had to be done abroad. He was glad to hear the opinion of Mr. Umney, as a manufacturer, with reference to the preparation of the extract; but it appeared to him that the examination of the extracts undoubtedly pointed to the fact that manufacturers either used a more dilute spirit or removed the oil. Mr. Umney appeared to think that the more dilute spirit was employed, and that the oil was not removed. The preferableness of proof spirit in the making of extract was not suggested in the paper, but, in the case of tincture, the paper pointed out that the stronger spirit was to be preferred, because it percolated better. It seemed desirable that, as far as possible, the composition of the present extract should be maintained. That extract had won its way as a therapeutic agent, and it would require therapeutic experiments before it could be said that the oil should be excluded. As to the use of acetic acid, he had never seen extract prepared by that means, and he did not consider that such a method was desirable, especially as nux-vomica could be exhausted by means of alcohol and water. With reference to what had been said by Dr. Symes, he was pleased to hear that Mr. Conroy's experiments were confirmatory; but at the same time he should have been glad to have heard earlier that Mr. Conroy had taken up the subject, for a great deal of trouble might have been saved thereby to Mr. Short and himself (Mr. Dunstan). Their present work was, however, begun before their paper was read at the Conference. As to the fact that the marc was found to be bitter, the marc in that case had been washed with a small quantity of alcohol before it was tasted, so that the associated tincture might be removed. Dr. Symes seemed to think that there were conflicting statements in the paper with reference to the strength of spirit. He would find that that statement was made with reference to maceration and percolation. Where percolation was used, and sodium chloride was employed, the marc was entirely free from

* The paper referred to by Dr. Symes, has been received and will be published next week.—Ed. Ph. J.

bitterness; and where alcohol and water, in the proportion of 100 to 25, was used, it was nearly free from bitterness.

The PRESIDENT said that it was extremely satisfactory to find that Mr. Conroy, Mr. Giles and others had confirmed the results obtained by the authors. With regard to the question of the Pharmacopœia, to which Mr. Giles had referred, it was one of those matters which were not likely to be lost sight of by the President of the Society. But he thought that they would agree that the time had not quite arrived for the commencement of a Pharmacopœia laboratory. This, however, was a matter which belonged to what in "another place" would be called politics, rather than to the subject of the paper.

A vote of thanks to the authors of the papers was then passed.

A paper was then read entitled—

TINCTURE OF CINCHONA.

BY EDWARD GRINDLE HOGG.

This was followed by a paper on—

THE ALKALOIDAL STRENGTH OF TINCTURE.

BY J. O. BRAITHWAITE.

The papers are printed on pp. 444 and 445, and gave rise to the following discussion:—

Professor ATTFIELD, referring to the table given in Mr. Hogg's paper, asked whether it was to be understood that the amount of alkaloid in the tincture and the amount of the alkaloid remaining in the marc together equalled the quantity of alkaloid in the bark. It did so in No. 1 and No. 3, but not in No. 2 and No. 4.

Mr. HOGG said that the separate quantities added together were intended to make up the amount originally contained in the bark. They did so exactly in two cases, but in those they were only taken by difference, while in No. 2 and No. 4 the figures were obtained by actual experiment.

Mr. EKIN said that the reason for the two papers which had been read was found in an observation credited to Dr. Paul in a discussion on the bark question last session. Mr. Hogg's paper referred to a difference between Dr. Paul's results and his (Mr. Ekin's) results, and the reference was justified by the remark of Dr. Paul, that he could not confirm his (Mr. Ekin's) statement. That statement was, that upon operating on a bark which contained 2 per cent. of total alkaloid soluble in ether, the bark having been specially selected for the purpose as being rich in quinic and quinovic acids, he was able to extract the whole of the alkaloid in the tincture. There was no question about that fact. Dr. Paul operated upon totally different barks, very rich in combined alkaloids and very rich in cinchotannic acid which, as was known, locked up the alkaloids very much. Hence Dr. Paul obtained different results, as might be expected. It was hardly scientific to say that Dr. Paul either agreed or disagreed with his (Mr. Ekin's) results, because the barks examined were totally different. Sample No. 3 in the paper corroborated the result at which he (Mr. Ekin) had arrived. Mr. Hogg had stated that he found that the tincture exhausted the bark about half, but that was hardly the case. No. 2 gave 38 per cent. in the tincture; No. 3, 30 per cent.; and No. 4 as much as 67 per cent. As Mr. Hogg said, probably this difference had nothing to do with the proportion of quinine; but he (the speaker) would suggest that in further investigations the quinic and cinchotannic acids should be investigated, for he considered that they affected the result very much. He thought that Mr. Braithwaite must have misunderstood him. He could not have suggested that a bark, rich in colouring matter, was likely to be rich in alkaloid. He saw no connection between the two.

Mr. NAYLOR wished to know from Mr. Braithwaite whether the relation between the ether and the total alkaloid was constant throughout his experiments. Apart from that, they did not know the significance of the ether residue.

Mr. UMNEY said that veterans in pharmacy must have laughed within themselves upon finding that for forty or fifty years they had been going on in such happy ignorance of the real value of tincture of cinchona. He was glad that young pharmacists were taking this and other preparations in hand and bringing chemical knowledge and experiment to elucidate those points which previously had been but little understood. It seemed pretty clear from the experiments of Mr. Hogg and Mr. Braithwaite that generally about 40 per cent. only of the alkaloid was dissolved; but he agreed with Mr. Ekin that no hard and fast line could be laid down. He (Mr. Umney) knew from experience that the extraction of alkaloids from barks rich in cinchotannic acid was not easy. In commerce they had what was known as soft *Carthagena* bark, which contained very little colouring matter. Then again, they had soft Columbian bark and quilled *Calisaya* bark. Also, there was flat *Calisaya* bark which possibly Mr. Hogg had operated upon, the true kind of which did not appear at the present time in the London drug market. All these varied in the degree in which they gave up their alkaloid. Mr. Naylor had correctly remarked that though an alkaloid was soluble in ether it by no means followed that it was quinine. In extracting cinchona barks with ether in making analyses, the cautious operator always converted into sulphate and waited for crystallization; indeed, one could only speak positively upon quinine when it was in a weighable crystalline form.

The PRESIDENT congratulated and welcomed Mr. Hogg on his first appearance as the reader of a paper in that room. As members of the Society they were glad to see one who had so comparatively recently passed through the School of Pharmacy presenting work which would do credit to the Society. As to Mr. Braithwaite, he had had some experience as a reader of papers, but they would desire to encourage him to continue his work in that and other directions.

A vote of thanks to the authors of the two papers was then passed.

Two papers were then read, entitled—

THE PURGATIVE PRINCIPLE OF CROTON OIL; AND THE VESICATING PRINCIPLE OF CROTON OIL.

BY HAROLD SENIER.

The papers are printed on p. 446, and gave rise to the following discussion:—

Dr. MEEK said that the experiments which he had made on the non-vesicating portion of croton oil seemed to show that in small doses it acted upon the stomach, and in larger doses upon the intestines without affecting the stomach. The smaller doses seemed to produce nausea and, in one case, vomiting; but those results were not produced when a larger dose was given to produce a purgative effect. The doses were given in the form of pills. It was a question whether the purgative action might not be much more speedy if the principle was dissolved in oil. It was difficult at present to speak of the value of this agent from a therapeutic point of view, for croton oil was very rarely given; but he should presume that the principle which Mr. Senier had described operated by producing a peristaltic action of the intestines.

Professor ATTFIELD said that one of the first questions which occurred in connection with a paper of this kind was as to the origin of the raw material employed by the worker. He believed that Mr. Senier had satisfied himself that the oil used in the present experiments was as genuine as that used in the experiments of 1867; but it was desirable that Mr. Senier should give some information on that point. He (Professor Attfield) must record his admiration of Mr. Senier's courage in swallowing a dose of the vesicating substance. As he had done that, he had, probably, tried the substance externally, and perhaps could tell them whether it was likely to be as useful as the vesicating material of cantharides.

Mr. SENIER, replying, said that he believed there was now only one presser of croton oil in England, and the oil which he had used was obtained from that source. When Professor Redwood wrote there was more than one source of supply in England, and he believed that Professor Redwood experimented on foreign oil as well as English. He (Mr. Senier) had had very little experience of cantharides in its most concentrated form. The vesicating principle of croton oil would vesicate in two hours, producing a number of watery blisters.

Thanks were accorded to the author of the papers and to Dr. Meek.

The PRESIDENT, in concluding the meeting, wished to say, in parenthesis, that it was a matter of extreme gratification to him, as an old student of the Society, that every paper read that evening had been written by or associated with some student of the School of Pharmacy. This fact showed that students, past and present, were interested in the progress of pharmacy, and it showed the importance of considering the subject to which Mr. Giles alluded in an earlier part of the evening.

Professor ATTFIELD acknowledged the compliment included in what had just fallen from the President. It was particularly pleasing to him (Professor Attfield) as the representative on that occasion of the school to which allusion had been made. The fact which the President had mentioned was largely due, however, to the encouragement which the Pharmaceutical Society had always given to the prosecution of original research, and also to the encouragement which they had given to the School of Pharmacy Students' Association. He believed that all the authors of the papers read that evening had been members or officers of that Association.

The next evening meeting was announced for Wednesday, February 6, 1884.

Provincial Transactions.

BRISTOL PHARMACEUTICAL ASSOCIATION.

A meeting of the above Association was held on Friday, November 23, at the Museum and Library, Queen's Road. The President, Mr. G. F. Schacht, in the chair.

Mr. White communicated the result of his observations of *Lithospermum purpureo-cœruleum*, with the object of drawing attention to some hitherto neglected points in the morphology of this beautiful wild flower. Although absent from the greater part of Britain, it grows in many spots in the west of England, and some of its stations being within the area of the Bristol coalfield, it can be regarded as a local plant. There are many old woods and coppices of oak, beech, and hazel nestling in the hollows and on the flanks of the Mendip range of hills where the soil is simply fragments of limestone with a little loam. The *Lithospermum* shelters amid the coarse herbage and entangled briars on the sunny fringes of these woods, seldom penetrating far into the shade, nor yet venturing more than a yard or two into the open ground. Although its mode of growth is well adapted for speedy travel over large tracts of ground, it does not spread; its limits being apparently restricted by some influence not easy to determine.

Botanical writers from the earliest times have named this species "the creeping Gromwell;" but notwithstanding that one or two old authors seem to have been correctly informed, none of the manuals in present use describe accurately the manner in which it is propagated. The plant is variously stated to have either a creeping root or prostrate creeping barren stems, and it is said also that the fruit is but rarely produced. Repeated examination at different seasons has brought out the fact that the root does not creep; that fruits are ripened on every cyme, if not in every calyx; and that the barren stems which rarely spring from a flowering root are primarily erect, then high-arching, and ultimately root at the tip, often at a considerable distance from the parent. These points with some others were illustrated by a series of dried specimens gathered near Congresbury, Somerset.

Mr. Algernon Warren read a paper upon "Scientific Discoveries which have, in the first instance, been the result of Accident." The cases especially dwelt upon were:—The improvements in the manufacture of pottery as developed by Astbury; the discoveries of Geber, Van Helmont, Paracelsus and Roger Bacon, during their vain endeavours to find the "elixir of life" and the "philosopher's stone;" those of Galvani in animal electricity, and the somewhat legendary accounts of the first production of glass and of the first hints obtained of the value of cinchona bark. Mr. Warren urged these considerations upon the attention of the younger portion of his audience as a motive for the exercise of a close observation of the minutest details connected with the processes of pharmacy.

The President then read a communication entitled "Suggestions for the Convenient Preparation of Sal-volatile, with a Note concerning the Element Time in Chemical Changes," in which he drew attention to the excellent paper by Dr. Thresh, read at the Evening Meeting of the Pharmaceutical Society on February 7 last, and especially to the fact that the process therein recommended not only produced good and constant results, but was one easy of adoption even by those whose appliances for manufacture generally were limited. He considered it the duty of pharmacists to insure, as far as possible, that the public obtained, for every individual pharmaceutical preparation demanded, the same thing wherever it was procured; and he hoped Dr. Thresh's recommendations would tempt many who were not in the habit of making their own sal volatile to do so for the future, and thus help to uniformity in this very popular remedy. He had to suggest two modifications of Dr. Thresh's process that would render its execution still more easy. First, that the essential oils be distilled with much less than the whole of the spirit—say one-sixth part—and mixed with the rest; this would permit the employment of much smaller apparatus and lessen the risk of accident. And, secondly, in the preparation of the ammonia solution, if (say in the production of 1 gallon of sal volatile) 4 oz. of powdered carbonate of ammonia, 8 oz. of stronger liquor ammoniæ, and 10 oz. of distilled water were mixed in a stoppered bottle and occasionally shaken *during two or three days at ordinary temperature*, there would be no necessity to heat the mixture to 140°—the molecular re-arrangement by which all the acid carbonate of ammonia is converted into the normal carbonate takes place gradually but completely—60° *plus* a longer time being equivalent for this purpose to 140° *plus* a shorter time. Heating a bottleful of ammonia to 140° might be attended with some amount of risk which would be completely avoided by the adoption of the above suggestion. Then, when the two liquids were prepared in the manner indicated and the aqueous one poured gradually into the spirituous, the mixture would take place without the deposition of a particle of ammonia salt. Undoubtedly, as Dr. Thresh had pointed out, if the ammonia solution were rapidly effected in the cold and added *at once* to the spirit a deposit of ammonia salt (the unchanged acid carbonate) would result, but if the solution were kept for days and then added, all would be well.

These points were illustrated experimentally and attention was drawn to the importance of the factor Time in the completion of, perhaps, all chemical changes that occurred in masses of matter.

Proceedings of Scientific Societies.

SOCIETY OF ARTS.

The Scientific Basis of Cookery.

A course of Cantor lectures was commenced on Monday, at the Society of Arts, upon "The Scientific Basis of Cookery," by W. Mattieu Williams. The lecturer introduced his subject by stating that he was not prepared to discourse upon technical cookery, but only intended to treat the subject technicologically, and he remarked upon the rapid progress being made in the extension of a knowledge of cookery among all classes. The technology of cookery, he said, included a branch of organic chemistry which was at present very imperfectly understood; and he compared the kitchen to a chemical laboratory in which certain chemical changes in the organic constituents of food are effected by the application of heat. Referring to the well-known properties of rough and polished surfaces as respectively good and bad radiators, he stated that radiation was the principal agent in the application of heat in cookery, and he also explained the difference between conduction and convection, as discovered by Rumford, which he described as a result consequent upon a philosopher burning his mouth whilst eating rice porirdge. Mr. Williams referred to the popular fallacies existing respecting the simple operation of the boiling of water, many people fancying that water when "boiling hard" is of a higher temperature than when just simmering, and being unaware of the enormous loss through heat becoming latent in the conversion of water into steam. The lecturer attributed the prevailing preference of roasted over baked meat, amongst the people of the middle class, to a prejudice having arisen from the old custom of baking their joints in a common oven, which, like the baker's oven, was also usually heated in a manner unsuitable for the cooking of meat. He advised that, in the operation of baking, meat should be submitted to a high temperature for the first few minutes, in order to obtain a coating of coagulated albumen which would prevent the juices of the meat from exuding; the temperature then to be lowered to the "cooking temperature" of 160° or 180° F., but to be again gradually raised shortly before the meat was completely cooked. Mr. Williams further stated that meat when baked sustains less loss in weight than when roasted, and that there is also less refuse. In regard to the method of cooking eggs by means of water at present in vogue, he considered it a bad one, and said that if an egg were kept in water at a temperature of 160° F. to 180° F. for about fifteen minutes, it would be much preferable to one *boiled* for three minutes, as is the custom, since the albumen of the egg was more uniformly coagulated and left in a more digestible condition; he also incidentally mentioned that he had lately observed that the yoke of an egg coagulates at a lower temperature than the white. The lecturer then remarked that many people believed that boiling and stewing were one and the same thing. This, he said, was completely erroneous, as meat intended to be boiled should be immersed in boiling water and the temperature maintained for the first few minutes to coagulate the outside albumen and thus *keep in* the juices; whilst in stewing the water should be raised gradually from a low to a high temperature in order to *extract* the juices. At the close of the first lecture, Mr. Williams remarked that the French were far in advance in researches in the science of cookery, and pointed out that as far back as forty years ago a commission had been appointed by the Academy of Sciences in Paris to report upon bone soup.

Manufacture of Mineral Waters.

At the ordinary weekly meeting on Wednesday evening, Mr. T. T. P. Bruce Warren read a paper upon "The Manufacture of Mineral Waters." The lecturer remarked at the commencement of his paper that he should purposely omit any account of the history of the manufacture, and only refer to the increase in the variety of non-alcoholic beverages and bottles as compared with those of a few years ago. He believed that this had no doubt induced consumers to regard such drinks less in the light of medicines, and to consider them pleasant and suitable beverages for the table. Mr. Warren stated that not long ago ginger, lemons, sugar, and citric and tartaric acids, were the only vegetable products used in their manufacture, and that these with a few inorganic salts might be said to have constituted the materia medica of this trade; owing, however, to the more general use of aerated waters, artistic skill had been developed and thus they had been greatly improved. One thing of the greatest importance, he said, was the use of pure wholesome water in the manufacture, and to the importance of this requirement the manufacturers were fully alive. Such water was generally obtained by filtering, though methods of distillation and boiling were also practised. The principal impurities of water were then referred to and the means taken to remove them. Mr. Warren next proceeded to give a detailed account of the process of manufacture, and of the machinery employed. He described the manufacture as consisting of three stages; the washing or purification of the carbonic acid gas, the saturation of the water with the gas, and the flavouring. He stated that an improvement had been effected by Mr. Forster in the saturation of the water with the gas. The old method had been to agitate the gas with the water in a copper vessel lined with tin; but by the new process they were allowed to fall through a series of fine perforations, thus becoming thoroughly mixed. The lecturer also mentioned that the whiting used for the generation of gas should be carefully stored, as it was greatly affected by damp, and had a great capacity for absorbing noxious vapours. He considered the operation of bottling a most important part of the manufacture, as if much free oxygen was present in the water the flavourings, especially if they consisted of essential oils, would be seriously affected. The mode generally adopted to overcome this was to exhaust the water of air before introducing the carbonic acid gas. He pointed out that great improvement had been made in the stoppers of the bottles, a great many patents for which had been taken out, the latest having been that of screw-stoppers. The lecturer specially mentioned the late Mr. Hooper as a successful manufacturer of imitation spa waters, which had arisen from a suggestion of Dr. Garrod.

In the discussion which followed, Dr. B. W. Richardson, the chairman, remarked that this paper showed that an important rivalry with alcoholic drinks had been established. Mr. Doyle, in speaking, stated that the demand for machinery for the manufacture of mineral waters had greatly increased, his firm alone having sold last year machines, the aggregate producing capacity of which would probably be about 3,000,000 bottles of soda water per day, some of the larger machines being capable of filling 3000 dozen bottles each daily. Mr. Foster referred to the impetus given to the trade by the introduction of small bottles or "splits," and expressed an opinion that if the sellers of aerated waters would be content with a more moderate rate of profit, one of the greatest drawbacks to the trade would be removed. He added that at present he was engaged in elaborating a method for the bottling of ales, in which all the atmospheric air would be removed from the liquor before bottling, and replaced by carbonic acid gas, and he affirmed that in ale so treated the intoxicating property of the alcohol was considerably modified, whilst the flavour remained unaffected.

Communications, Letters, etc., have been received from Messrs. Moeller, Learoyd, Thompson, Conroy, Samuel, Potter, Griffin and Co., Dyer, Allen, Sandford, Waverley, Fraxinus.

TINCTURE OF NUX-VOMICA.*

BY MICHAEL CONROY, F.C.S.

In the discussion which followed the reading of Messrs. Dunstan and Short's excellent paper on Tincture of Nux-vomica at the recent Pharmaceutical Conference at Southport, I ventured to suggest that the variation in the alkaloidal strength of the samples which they had analysed might possibly be due, in some measure, to the alcoholic strength of the spirit employed in their preparation; since in the table showing the analytical results of the twelve samples, those tinctures of higher specific gravity, and presumable lower alcoholic strength, were, as a rule, richer in alkaloids than those of lower specific gravity and higher alcoholic strength. To make this clear it will be necessary to reproduce Messrs. Dunstan and Short's table.

Analysis of Tinctures of Nux-Vomica.

No.	Specific gravity.	Percent of total alkaloid	Percentage of strychnine	Percentage of brucine.
1	0·8426	0·224	0·077	0·147
2	0·8409	0·262	0·097	0·165
3	0·8438	0·208	0·068	0·140
4	0·8392	0·124	0·049	0·075
5	0·8450	0·360	0·121	0·239
6	0·8378	0·211	0·084	0·127
7	0·8377	0·136	0·046	0·090
8	0·8552	0·181	0·066	0·115
9	0·8398	0·196	0·077	0·119
10	0·8413	0·189	0·087	0·102
11	0·8407	0·168	0·060	0·108
12	0·8436	0·263	0·131	0·132

If this table be analysed by separating the six tinctures showing the higher from the six showing the lower specific gravity, we find that the average specific gravity of the first six is 0·8452 with an average alkaloidal strength of 0·237; against specific gravity 0·8393 and an average alkaloidal strength of 0·183 in the second six, thus:—

Tincture of high sp. gr.			Tincture of low sp. gr.		
No.	Sp. gr.	Percentage total alkaloid.	No.	Sp. gr.	Percentage total alkaloid.
1	0·8426	0·224	2	0·8409	0·262
3	0·8438	0·208	4	0·8392	0·124
5	0·8450	0·360	6	0·8378	0·211
8	0·8552	0·181	7	0·8377	0·136
10	0·8413	0·189	9	0·8398	0·196
12	0·8436	0·263	11	0·8407	0·168
Average	0·8452	0·237	Average	0·8393	0·183

On thus examining the figures, a strong *primâ facie* case against strong alcoholic menstruum presents itself for further investigation, notwithstanding that there are other causes that would affect the alkaloidal strength of the tincture, such as the variable quality of nux-vomica, careless manipulation, insufficient comminution of the seeds, etc. The specific gravity may also vary in a legitimate manner, though not to the extent above shown, from two causes: firstly, by the amount of extractive matter contained in the seeds, which is as variable as the amount of alkaloid they contain, though it does not necessarily follow that seeds yielding a high percentage of extract should give a corresponding amount of alkaloid; secondly, by the dehydrating influence of spirit of this strength upon the powdered seeds which, by abstracting the moisture usually contained, would become of greater specific gravity. On the other hand, it is not at all probable that nux-vomica powder, even if thoroughly dry, could dehydrate the rectified spirit of the Pharmacopœia, so as to produce a tincture of less specific gravity than the menstruum used, as shown in 6 and 7. I am consequently forced to the opinion that a stronger than the official spirit of specific gravity ·838 has been used in these and in some of the other cases of low specific gravity.

A few degrees difference in the strength of an alcoholic menstruum would, in the case of nux-vomica, which contains so much albumen, considerably affect the resulting tincture in strength, from the fact that strong alcohol, by abstracting water, would harden the thick parenchyma of the cell walls, and thus render them impermeable to its action; while the water contained in a weaker spirituous menstruum would swell up and soften the cell walls and thus, by osmotic action, enable this description of menstruum to reach their interior and extract the soluble matter.

With the object, therefore, of testing the action of alcoholic menstrua of various dilutions, the following experiments were put in hand. In each case the B.P. process was followed, and the same nux-vomica used. This was carefully reduced to powder in the usual manner and passed through a silk sieve of 100 meshes to the square inch.

No. 1 made with proof spirit, specific gravity 0·920.

No. 2 made with a mixture of half proof and half rectified spirit, specific gravity 0·882.

No. 3 made with rectified spirit, specific gravity 0·838.

No. 4 made with rectified spirit, specific gravity 0·830.

No. 5 made with a mixture of equal parts absolute alcohol and rectified spirit, specific gravity 0·820.

No. 6 made with absolute alcohol, specific gravity 0·795.

These tinctures after completion were tested as follows:—1000 grain measures of each, representing 100 grains of nux-vomica, were evaporated, and the resulting extract dried until it ceased to lose weight. The alkaloids were next extracted and separated by Messrs. Dunstan and Short's method. The results are fully stated in the following table.

Analyses of Tinctures of Nux-vomica prepared with Menstrua of various Alcoholic Strength.

No.	Sp. gr. of menstruum used at 60° F.	Sp. gr. of tincture at 60° F.	Percentage of dry extract from tincture.	Percentage of total alkaloids.	Percentage of strychnine.	Percentage of brucine.
1	0·920	0·924	1·353	0·209	0·083	0·126
2	0·882	0·886	1·320	0·209	0·084	0·125
3	0·838	0·842	1·056	0·190	0·077	0·113
4	0·830	0·834	0·957	0·119	0·045	0·074
5	0·820	0·823	0·803	0·081	0·030	0·051
6	0 795	0·798	0·748	0·032	—	—

From this it is seen that both the extractive and alkaloidal strengths of the tinctures decrease in proportion as their alcoholic strength increases, except

* Read at a meeting of the Liverpool Chemists' Association, November 22.

in the case of No. 3, which represents the B.P. menstruum. In this, although we find an important decrease in both extract and alkaloid, the proportion of alkaloid to extract is greater than in any of the other tinctures. For instance, No. 2 gives 1·320 grains per cent. of extract to 0·209 grain of total alkaloid, while No. 3 yields only 1·056 grains of extract to ·190 of total alkaloid, whereas to be proportionate with No. 2 it should only yield 0·167 per cent.; thus $\frac{1·056 \times ·209}{1·320} = 0·167$. In Nos. 4, 5 and 6 there is a greater decrease in the alkaloids than is shown in the extract, and this is due to the fact that the oil of the seeds was taken up in these experiments, and more especially in No. 6, by the menstruum used.

In reference to the relative proportion of strychnine to brucine, I scarcely expected to find any variation, and the result, which in each case is the average of two determinations, fully bears this out. Before leaving this part of the subject I must ask to bear testimony to the great excellence of the method devised by Messrs. Dunstan and Short for the separation of these alkaloids. The plan is simple, expeditious and reliable.

The deduction to be drawn from these experiments is that the rectified spirit of the Pharmacopœia, and spirit containing a higher percentage of alcohol, are unsuitable menstrua for the extraction of the active properties of nux vomica, for the reason that they harden up and cannot freely penetrate the cell walls; whilst menstrua of the strength of No. 1 and 2 do this completely, and thoroughly exhaust the powder. Either of these would advantageously replace the rectified spirit now used in the official process, since both produce tinctures of superior quality. No. 2 is superior to No. 1 menstruum, inasmuch that it does not swell up the powder to the same extent, and consequently percolates more freely.

Another important point in connection with this and other tinctures of such powerful therapeutic potency is the adoption of some method of insuring greater uniformity of strength than at present exists. With this tincture some means of attaining this end are of vital importance, on account of the very variable nature of the nux-vomica found in commerce, and some years ago Mr. Siebold suggested that it be made from the extract, which would to some extent attain the object in view. His suggestion, in what may be termed an improved method, appears to have been adopted in the new U.S.P., which directs that 20 parts of nux-vomica, in "No 60 powder," be extracted by percolation with a menstruum consisting of 8 parts of alcohol, specific gravity 0·820 and 1 part of water. The first 90 parts of the percolate is reserved and the remainder evaporated to 10 parts and mixed with the reserved portion. A convenient quantity of this tincture is then taken and evaporated in a water-bath to dryness, and from the weight thus obtained a calculation is made and the tincture diluted with more of the menstruum so that it will contain 2 per cent of dry extract.

The evaporation here mentioned would be quite unnecessary were a less alcoholic and more suitable menstruum employed, since there should be no difficulty in thoroughly exhausting 20 parts of powdered nux-vomica with sufficient menstruum to produce 100 parts. The point, however, to which I wish to allude is the mode of assaying the tincture that is adopted This is defective, inasmuch as it gives extractive instead of alkaloidal strength; whereas with very little more trouble the percentage of total alkaloids could be obtained, and the tincture standardized on this basis.

In conclusion I have to express my thanks to Messrs. Evans, Sons and Co. for supplying the materials and allowing these experiments to be conducted in their laboratories.

VEGETABLE TALLOW FROM SINGAPORE.

BY W. T. THISELTON DYER, C.M.G., M.A., F.L.S.

The very interesting note on the above substance, by Mr. Holmes, in a late number of the *Pharmaceutical Journal* (November 24, 1883, p. 401), requires a word of comment. We have not, as far as I know, received a specimen of the vegetable tallow known as "Minjak Tankawang." But Madame de Vries de Vries, who was lately on a visit to England, brought to Kew, on behalf of Professor Van Eeden, of Haarlem, a specimen of a plant of which he informed Sir Joseph Hooker, in a letter (November 11, 1883), the "Indian name is Minjak Tangkawang, and it yields a fat." I have little doubt, therefore, that this is the plant which yields the vegetable tallow about which Mr. Holmes has written. Madame de Vries de Vries added that Professor Van Eeden "had shown his plant to Mons. Pierre, from Charenton, author of a Flore forestière de Cochinchine, whom perhaps you know. Mons. Pierre thought it likely the plant is no *Hopea*, but belongs to the *Sapotaceæ*."

This opinion is certainly correct. The plant is no *Hopea*, but, undoubtedly, *Sapotaceous*. The curious point, however, is that my colleague, Professor Oliver, informs me that he is unable to refer it to any known genus of the order. For the present then, till more complete material is obtained, it must remain undescribed. Madame de Vries de Vries adds in a subsequent letter that "the plant .... came from Bandjermassing, Isle of Borneo."

The name, Minjak Tankawang, has been applied to many *Dipterocarpeæ*, especially Hopeas, and W. H. de Vriese published in 1861, at Leyden, a folio tract under this name, containing a number of descriptions of new species. It is *à priori* unlikely, however, that any species of *Dipterocarpeæ* would yield a vegetable tallow from the seeds, because the members of the family are characterized by the presence of oleo-resins in the tissues and not of fatty bodies. On the other hand, the seeds of *Sapotaceæ* are rich in the latter class of substances, *e.g.*, argan oil from *Argania Sideroxylon*, mee oil from *Bassia longifolia*, shea butter from *Butyrospermum Parkii.*

I suspect that Mr. Holmes's specimens will prove identical with a substance which has long been known and which in the Kew Museum is referred doubtfully to a species of *Bassia*. We possess specimens of "Tankawang oil" and the decorticated seeds which yield it, which came to us from the India Museum. They are labelled "Borneo, *Bassia* sp." We also have an old Kew specimen labelled "Concrete oil from a species of *Bassia*; Sakarran; Sir James Brooke," which is probably the same thing.

We may fairly, I think, hope that now the origin of this interesting substance has attracted the attention of Mr. Holmes and Professor Van Eeden, the doubts attending it will be cleared up. As a contribution to this end I have written this brief note.

THE PREPARATION OF PURE BENZOIC ACID FROM URINE.*

BY T. S. DYMOND.

[Contribution from the Research Fund of the School of Pharmacy Students' Association.]

In the production of some glycocine from hippuric acid, for the confirmation of the reported synthesis of uric acid, the results of which investigation I partly brought before this Association last year, I obtained as a bye-product—benzoic acid. The preparation of benzoic acid in this way is interesting, because it is indirectly obtained from urine, hippuric acid being derived from that source, and because the use of such benzoic acid, which, as hitherto prepared, retains the odour of urine, is prohibited by British, German and United States Pharmacopœias. This being the case, I have made a few experiments to determine in what way benzoic acid thus obtained differs from that obtained from gum benzoin.

Preparation.—The commercial method of preparing benzoic acid from urine is by boiling putrid urine (which contains the hippuric acid in solution) with hydrochloric acid. A purer body will obviously be obtained at little more expense by first separating the hippuric acid, and this now is frequently done commercially. The phosphates in the urine taken are precipitated by lime. The urine is neutralized with hydrochloric acid, and evaporated to a low bulk. Strong hydrochloric acid is then added in excess, and the hippuric acid which separates is washed and recrystallized and sometimes further purified and decolorized. The purified hippuric acid is then heated with strong hydrochloric acid and the mixture kept at its boiling point till the hippuric acid has entirely disappeared and dark oily drops of benzoic acid have begun to form. On cooling and adding water the benzoic acid crystallizes out in the form of flattened plates, which are washed and dried.

$$\left\{\begin{array}{l} CH_2.(NH.C_7H_5O) \\ CO.OH \end{array}\right. + \left\{\begin{array}{l} H \\ OH \end{array}\right. =$$

Benzamidoacetic Acid + Water= or Hippuric Acid.

$$\left\{\begin{array}{l} CH_2.NH_2 \\ COOH \end{array}\right. + \left\{\begin{array}{l} C_7H_5O \\ OH \end{array}\right. \text{ or } \left\{\begin{array}{l} C_6H_5 \\ COOH \end{array}\right.$$

Amidoacetic Acid or Glycocine. + Benzoic Acid

Benzoic acid thus obtained has that peculiar urine-like odour which quite unfits it for use in medicine.

I have found, however, that when this impure acid is carefully sublimed, it can be obtained in a state of perfect purity and in beautiful crystals, which recrystallize from water in a form different from that in which the acid crystallizes before sublimation, but identical with that in which benzoic acid obtained from gum crystallizes.

Tests.—The only test in the British Pharmacopœia for benzoic acid is that of smell—benzoic acid is to have an agreeable aromatic odour resembling that of benzoin. As gum benzoin differs very much in smell, some specimens containing styrol, and others vanillin, while others have no particular odour, as the specimen of Palembang gum from the Museum of the Pharmaceutical Society, there is much commercial benzoic acid which does not answer to this test and has not the aroma which it is understood gum benzoin should have.

* Read at a meeting of the School of Pharmacy Students' Association, November 29.

In the German Pharmacopœia there are three tests. The acid is to have the smell of benzoin and also an empyreumatic odour, and is to be of a yellowish or yellow-brown colour. This is to ensure the acid being prepared by direct sublimation of the gum. However, benzoic acid thus made, if the operation be performed with care and at a low temperature, may be quite colourless. It is a pity that the acid should be required to be contaminated, simply to prevent adulteration with acid obtained from other sources. In order to obtain it colourless a temperature of 160° C. is quite high enough for the sublimation of the whole of the acid. At first water and dark coloured hydrocarbons volatilize together with some benzoic acid; these must be allowed to escape for two or three hours. The benzoic acid may then be collected, a free outlet being always allowed for the less readily condensible vapours.

Before the end of the operation all these vapours will have passed away and the temperature may be raised even to 230° C. without any risk of contaminating the acid.

The second test is to prove the absence of cinnamic acid, and depends on the fact that the odour of oil of bitter almonds is evolved when cinnamic acid is warmed with an oxidizing agent. It is difficult to get benzoic acid, which has been sublimed directly from gum, always free from cinnamic acid; for all varieties of benzoin occasionally contain this acid, and sometimes it has been said no benzoic acid ('Pharmacographia'); and it is only by the lime extraction method that the cinnamic acid could be got rid of, as it sublimes in the same way as benzoic acid.

The third test is to prove the presence of volatile hydrocarbons, and depends on the fact that known quantities of styrol and vanillin and some other liquid hydrocarbons reduce a known quantity of solution of permanganate of potassium in a certain time. This test is also faulty, for if a few drops of permanganate solution be added to a crystallized solution of the impure urine-benzoic acid, decolorization occurs in a very short time, although no styrol or other aromatic hydrocarbon is present. Almost any organic matter indeed will effect this change.

The United States Pharmacopœia implies that benzoic acid must be made from benzoin by extraction with lime, for the acid is to be white and to have only a faint aromatic odour of benzoin. It is not to have the smell of oil of bitter almonds or stale urine, thus preventing the use of benzoic acid prepared from toluene or from urine.

Two additional tests are given.

1. A solution of benzoic acid in pure cold sulphuric acid, when gently warmed, should not turn darker than a light brown. This is a good test for the absence of organic impurity.

2. Benzoic acid mixed with freshly ignited and moistened cupric oxide should not yield a green coloration to the flame when applied on a platinum wire. This test is meant to prove the absence of chlorobenzoic acid, which may occur as an impurity if the benzoic has been made from toluene. It must be performed with great care, for if the mixture be allowed to get too hot, the cupric oxide combines with the benzoic acid, and colours the flame an intense green. The mass then must be kept moist. It will be seen from these tests that all the Pharma

copœias require that benzoic acid must be prepared from gum benzoin. The German Pharmacopœia directs that it is to be made by sublimation, have a yellowish-brown colour, aromatic odour, and contain a substance (styrol ?) capable of reducing potassium permanganate. Hence the benzoic acid of the German Pharmacopœia is not intended to be chemically pure. The United States Pharmacopœia indicates that it should be prepared by the lime method and be chemically pure. Urine-benzoic acid can never answer to the tests for the former, but when prepared by the method above described, it will be seen that it comes up to the standard imposed by the tests for the latter.

The following table shows how five specimens of benzoic acid compare with each other:—

	Urine benzoic acid unsublimed.	Urine benzoic acid sublimed.	Benzoic acid extracted with lime from Palembang gum.	A commercial specimen of benzoic acid.	Benzoic acid sublimed from Penang gum.
Solution in cold H_2SO_4 when warmed is	Dark brown.	Light brown.	Light brown.	Light brown.	Dark brown.
Mixed with moist CuO gives in the flame	No green tinge.	No green tinge.	No green tinge.	No green tinge.	No green tinge.
Warmed with solution of $K_2Mn_2O_8$ gives	No odour.	No odour.	No odour.	No odour.	Smell of oil of bitter almonds.
A cold solution with $K_2Mn_2O_8$ becomes	Colourless in 5 minutes.	Not colourless in 12 hours.	Not colourless in 12 hours.	Not colourless in 12 hours.	Colourless in 5 minutes.
Crystallizes from an aqueous solution in	Prismatic needles.	Flaky crystals.	Flaky crystals.	Flaky crystals.	Small needles.
Odour	Like urine.	Faintly aromatic.	Faintly aromatic.	Disagreeably aromatic.	Strongly aromatic.

It would appear then that benzoic acid prepared from hippuric acid is totally unfit for use in medicine, unless it has been sublimed. When sublimed its character is entirely changed. Instead of crystallizing from water in large prisms, it does so in flaky crystals like the natural varieties. It has lost its offensive smell and has even a faint aromatic odour. It is purer than the acid obtained by direct sublimation of the gum, for it does not contain any volatile hydrocarbons, and solution of permanganate of potassium was only decolorized after long standing. It is pure benzoic acid and is identical with the specimen of acid extracted by lime from Palembang benzoin.

From these experiments it will also be seen that the absence of urine-like odour in a sample of benzoic acid and its conformity to the United States Pharmacopœia tests cannot be taken as indicating that it has not been prepared from urine.

My thanks are due to Mr. Holmes for the assistance he has given me in the identification of the resins, and to Mr. Dunstan for his suggestions and help while working in the Laboratories of the Pharmaceutical Society.

SKETCHES OF TYNESIDE TECHNOLOGY.*

BY B. S. PROCTOR.

In 1868 Mr. Isaac Lowthian Bell read to the Newcastle Chemical Society its first inaugural address. In December, 1882, it fell to my lot to read the final address to the same Society, and it now is my duty to read to you the first inaugural address of the Newcastle Section of the Society of Chemical Industry.

These events mark certain stages in the chemical history of our neighbourhood, and suggest a review of the changes which have taken place, and which have been to some considerable extent chronicled in the transactions of the former Society.

In 1868 we find Mr. Bell sketching the history of the alkali manufacture on the Tyne, from the days of Dundonald and Losh, in the infancy of the Leblanc process. We find him remarking that other chemical industries of our neighbourhood commenced long before that time, glass manufacture, for example, dating two hundred and fifty years ago. We note, not without agreement, his remark that our local chemical industries being so numerous, and of so early a date, the initiation of a Chemical Society might have taken place before the year 1868.

We find him comparing and contrasting the operations of the test-tube and blow-pipe with the great operations of the tank and the furnace, where bulk and long continued action tend so much to modify the results; and in turn comparing or contrasting the operations of the manufacturer with the greater and more protracted operations of nature, as we read the results tabulated in geological strata. He traces how observation leads to experiment, and experiment to the manufacturing process, quoting in illustration Neilson's adoption of the hot blast, and Pattinson's process for the desilverization of lead.

He points to the combination of mechanical ingenuity and chemical skill which produced Swan's photographic carbon printing, a combination of talents which is highly desirable in the experimental chemist, and absolutely essential to any distinguished success on the part of anyone developing a new chemical industry—a position in which my illustrious predecessor has become so well known. Mr. Bell then points to the aid rendered by chemical knowledge when the Neapolitan Government raised the price of sulphur, and how esparto grass was brought to the relief of the paper manufacture when the supply of rags was unequal to the increasing demand for printing paper—a temporary difficulty proving in these, as in many other cases, to be the seed of future development. In commercial chemistry it is the money difficulty which is usually the incentive to the new departure. In theoretical chemistry the incentive is generally a difficulty in explaining some particular phenomenon, as illustrated in Mr. Bell's next example, how the difficulty of reasonably accounting for Fraunhofer's lines incited many observers to study the subject, and, ultimately leading Kirchhoff to the first steps in spectrum analysis, laid the foundation of stellar chemistry. Mr. Bell next illustrates with an experiment the phenomenon of supersaturation and the starting of crystallization by the con-

* Address delivered on October 4 to the Newcastle Section of the Society of Chemical Industry on the occasion of the opening of the Session 1883-84.

tact of a mote-laden atmosphere. He sketches some of the theories regarding the cause of air so acting, and connects these phenomena with the initiation of putrefaction and disease by the floating of germs in the air. Finally he urges greater economy in the use of fuel, that the root of our prosperity may be lasting. Many of these subjects have had repeated notice at the meetings which we have held during the fourteen years of our existence as a Newcastle Chemical Society, and we note the progress which has been made in knowledge by the papers which have been read and the discussions which have taken place in connection with them.

Turning again to the first of these subjects, first in importance as well as first in order—the alkali manufacture — we find numerous contributions of matter relating to it. First, the late Mr. R. C. Clapham, in 1870, gave us an interesting paper on the manufacture of soda from salt by its decomposition with litharge, a process introduced by Lord Dundonald in 1790, and worked on a manufacturing scale by Mr. William Losh, in 1799, with the striking result that 100 tons of salt treated with 300 tons of litharge yielded 3 tons of caustic soda. The undecomposed salt was of course recovered and the lead re-smelted for another operation. With so small a yield from so large an operation it is not surprizing to learn that the value of a 70 per cent. caustic soda was then £85 to £90 per ton. The process which Mr. Clapham himself worked in 1869 to 1870 at Walker was a modification of this as patented by Mr. Bachet. But with all the progress of theoretical and practical chemistry during three quarters of a century, the difficulties of the process had been but partially overcome, and the gain in this direction had been outstripped by the greater advances in other methods of manufacture and the consequent progress downwards in chemical prices. Though Mr. Clapham's experiments led to effecting a decomposition of about 50 per cent. of the salt instead of 5 per cent., to using the oxide of lead many times without resmelting, and to avoiding small losses of lead by refinements of operation—though the great sulphuric acid chambers were rendered unnecessary, and the heaps of tank waste promised to be no longer a thorn in the side of the chemical works, yet the process was relinquished as being less satisfactory than that of Leblanc.

In December, 1870, Mr. Glover tells us in his inaugural address that the alkali manufacture still awaits the coming man, not to introduce a shorter process than the Leblanc, but rather to perfect that system. Now we must admit, though Mr. Glover cries out against the imperfection of the Leblanc method and the losses of soda that occur at its various stages—the loss of 2 or 3 per cent. in converting salt into sulphate, and the loss of 10 per cent. in converting sulphate into soda ash—this margin of theoretically preventable loss is too small to encourage any hope of the perfecting of the process, prolonging its vitality in the face of any new series of reactions which could give a substantial advantage in other respects.

At the meeting in March, 1872, Mr. Clapham again reported the progress made in trying the Bachet system on the manfacturing scale, and in his paper he said that the experiments "in a merely commercial sense are not yet successful."

It is to the honour of Mr. Clapham and his partners that he battled so long against the difficulties of making a new process profitable. Had the pecuniary result been satisfactory, paying the way of work and utimately paving it with gold, we should have heard much of him as a pioneer of progress, and it is well for us to remember and to honour the man who works in faith and reaps no reward. It is not, however, without some feeling of satisfaction that we see the soda manufacture saved from association with such an insidious poison as lead. Soda enters continually into our medicine, our beverages, and our food, besides its application to our skins as soap; and if a fraction only of the 5 per cent. of lead which he lost found its way into these articles of daily and hourly consumption, the health of the community would almost certainly suffer.

Dr. Lunge in his inaugural address of October, 1872, gave an account of an alkali process which he had attempted to found upon the reaction described by Professor Wagner, in which bicarbonate of baryta effects the decomposition of sulphate of soda. This Dr. Lunge modified by using sulphate of soda, carbonate of baryta, and carbonic acid, obtaining his carbonate of baryta by precipitating the sulphide with carbonic acid, and obtaining his carbonic acid from a limekiln. There are two points in which this process is essentially wanting in the characters likely to make it attractive: the most important is that it starts with sulphate of soda instead of salt, and consequently leaves untouched the necessity for the sulphuric acid works and the consumption of the equivalent of HCl. In the second place it works with a poisonous material. Baryta, however, is of a character much less objectionable than lead. But these objections would not have retarded its adoption had the pecuniary experience proved favourable. The obtaining of the theoretical yield of alkali, instead of losing 12 per cent., as is common in the Leblanc process, affords no compensation for the increased cost of working, though it may be theoretically better chemistry to obtain the greatest possible yield and a product of the greatest possible purity.

After describing his own experiments, which had not threatened to disturb the old lines of action, Dr. Lunge notices such innovations as at that time were more imminent of a revolution. "What between Hargreaves, Young, Weldon, and Deacon, not to mention many others," says Dr. Lunge, "nearly all the time-honoured plant of the alkali works seems to be doomed to destruction." He adds, however: "Somehow or other the great revolution has not yet been accomplished. The old plant is still in existence everywhere, only augmented here and there by an appendix according to Weldon or Deacon."

In the following year Dr. Lunge again comments upon the alkali manufacture, but in 1873 the ammonia process had come into prominence—a process which had its origin under patent by Dyar and Hemming in 1838, and which had undergone improvements at the hands of various manufacturers between that time and 1873, but never gained a footing as a successful competitor of the Leblanc system till about that time, when, as Dr. Lunge informs us, "many factories are in the course of erection, one of them for a production of nearly 100 tons of soda ash per week." But he still looks upon its position as only threatening rather than actually competing with the older one, for he adds: "If the ammonia process really should be the process of the future, it is quite evident that those localities will have the best chance for it where strong brine is to be had for next to nothing, and that the manufacture of alkali will shift to different localities from the present;" and he exhorts the workers by Leblanc's method to use every care and adopt every improvement, that they may be able to compete with any other process in the future.

In 1874 Mr. John Pattinson reviews the progress of a few preceding years, and comments upon the secrecy which at that time surrounded the proceedings of Messrs. Brunner and Mond, at Northwich, but quotes the opinion at that time held by Mr. Weldon, that the ammonia process is "so slow, and the apparatus so expensive, that it could not be economically worked." In the next paragraph Mr. Pattinson reports that the "Hargreaves process of decomposing common salt is now making considerable progress." Again, in 1875, he reports that the alkali manufacture "in its main features still remains the same as when it left the hands of the famous Leblanc." "The only rival plan which has hitherto met with any measure of success is the so-called ammonia process. In England this process is now carried on, somewhat extensively I believe, by Messrs. Brunner and Mond." So we note the quiet, almost stealthy advance of this great revolution. Leblanc had ruled so long, competitors had been so many and so short-lived, that it was difficult to believe anyone would come with power to overthrow the elaborate and long-established system of the alkali works. The excellent quality of the ammonia-soda is noted with appreciation, and Mr. Pattinson, speaking with the caution of one who knows that he does not know all particulars, adds, "It is said that the plant is very liable to get out of order, and that the alkali is produced at a very high cost;" and, "Moreover, it is said that 5 per cent. of the ammonia used in the process is lost for every ton of alkali made." The last paper on the alkali manufacture which appears in the transactions of the Newcastle Chemical Society is from the German of Hasenclever, and is mainly devoted to reviewing the relative advantages and importance of the Leblanc and the ammonia processes in the production of German alkali. But now, in 1880, they are regarded as equals in importance, if, indeed, the ammonia process has not asserted its superiority; for in the estimation of their relative costs the Leblanc process only shows to equal advantage by including in this estimate the value of hydrochloric acid as 1*s.* and the recovered sulphur as 3*s.* on the 100 kilos. of 100 per cent. soda produced, and the writer admits that "on the relative advantages of the one process or the other no exact judgment can as yet be formed." Since that time the Leblanc process has had a desperate struggle for life. At any rate, in our own neighbourhood this is evidenced by the numerous ruined castles of that industry which stud the Northumbrian shore of the Tyne.

In your society, gentlemen, I feel that it would be presumptuous to offer, or even to hold, any opinion on the future prospects of the alkali trade of the Tyne. I will therefore pass on to notice more briefly some of the other subjects which offer some material for technical history, as they are recorded in our five small volumes of transactions.

Of the various chemical operations which have a special local interest, the desilverization of lead is next in importance to the alkali manufacture. The Pattinsonization of lead has remained essentially the same as it was when first worked out by the late Hugh Lee Pattinson, and is the mode by which the greatest part of the lead of commerce is purified up to the present time. The first notice of this subject in our transactions is by Mr. John Pattinson, in his address, in October, 1875, where he briefly describes Rozan's improvement upon Pattinson's original mode of working, and then describes the modification of Parke's method as worked by Messrs. Locke, Blackett, and Company, in which the silver is separated by adding zinc to the melted lead. Both these processes are again alluded to in 1878 by Mr. Clapham, but without indicating any change in the mode of working. A month later Mr. N. Cookson presented us with a valuable paper on the Rozan process as carried on at his works.

In 1882 we had short but important communications from Mr. Glover and Mr. Cookson, in which they dissipate the fiction that the alloys of lead with small proportions of antimony or copper are less acted on by sulphuric acid than is pure lead.

Sulphur, its economy and recovery from alkali waste has been under consideration at several of our meetings. Perhaps the most important of these occasions was the supplementary meeting to our first session, when Mr. Mond described the process he had then recently introduced, blowing air through tank waste till partial oxidation is effected and soluble sulphur compounds formed, including hyposulphite of lime, bisulphide of calcium and sulphydrate of calcium, the proportions of which can be regulated by the degree of oxidation, and when so regulated the addition of HCl effects the precipitation of sulphur without evolution of sulphuretted hydrogen.

In the following year sulphur comes in for the passing comment that its disappearance from the alkali works, having abdicated in favour of pyrites, was the occasion of the appearance of the copper manufacture on the Tyne. Notwithstanding the importance of the subject nothing more of note was submitted to the Newcastle Chemical Society.

Economy in consumption of fuel has been treated in many papers, but only in an incidental way. The subject being a pressing one in every manufacture, and in almost every process, has been continually before us as an element, favourable or otherwise, in almost all proposed changes. Fuel, as coal and gas, has been the subject of several papers of importance, Mr. Pattinson's on gas and gas-burners having excited much interest, especially in this neighbourhood. In the first of these papers he showed that burners in actual use in Newcastle were only capable of yielding a light equal to $3\frac{4}{5}$ candles from a consumption of gas which should have produced $17\frac{3}{4}$ candle-light if burned to the best advantage. The pointing out of so glaring an extravagance could not fail to attract attention, both on the part of consumers who were getting less than quarter the value for their money, and on the parts of producers of gas who had a reputation to keep up regarding the illuminating power of their product. Nor were the makers of gas-burners slow to see the advantage of a paper which showed that new lamps were better than old ones. This paper was followed by a second from the same author at the next meeting (Feb., 1876), in which he pointed out the merits of the most recently improved burners, and of the clear glass and obscured globes.

In January, 1882, he again addressed us on the subject of gas-lighting, his object on this occasion being to show the merits and demerits of increasing the illuminating power of gas by impregnating it with the vapour of naphthalene, a subject which at the time was attracting much attention in the town. Improved Bunsen burners was the subject of an interesting paper by Mr. Wallace in 1875.

In 1876 the explosions of coal-dust in mines was the subject of comment from Professor Marreco, whose experiments in that direction were of great importance; and in 1878 Mr. Pattinson commented on the quality of the small coal used on the Tyne. Closely allied to these are several important papers on furnaces.

In 1872 Mr. Gibb described his mechanical calcining furnace. Jones and Walsh's decomposing furnace formed the subject of a paper by Mr. Clapham in 1876; and Mr. Mactear described his development of a mechanical furnace in its application to alkali manufacture in 1878. In the following year Mr. Berkley gave us a paper on magnesium limestone bricks as a furnace material capable of withstanding the highest heats which a furnace can produce.

At the meeting in December, 1878, Mr. Swan exhibited a rod of carbon which had become bent while heated *in vacuo* by a powerful electric current, remarking that it had become curved "as if from softening." The sooty deposit which had taken place on the inside of this lamp formed the subject of a note by myself in March, 1879, and another from Mr. Swan in December of the same year. The conclusion at that time arrived at was that the carbon was mechanically carried from the ignited filament to the sides of the containing vessel by the action of the residual air, and not truly in the condition of vapour. In connection with this, we should probably ask, What is vapour?

In the *Philosophical Magazine* for July, 1883, Dr. Fleming describes the deposit of copper on the inside of Edison lamps, apparently according to the laws of radiant matter. One of the points of difference between the Edison lamp and that of our townsman is that Edison unites his carbon to the platinum conducting wires by means of copper clamps, the carbon filament being electrotyped with copper to insure good electrical contact. In Swan lamps the globe contains no material but the carbon film, platinum wire conductors, and an infinitesimal residuum of air. Dr. Fleming says that when carbon is deposited on the inside of the Edison lamp it is in a continuous coat, but when copper is so deposited the molecules appear to be thrown off in straight lines from the point of heated metal, so that a shadow of the carbon filament is thrown upon the opposite side of the globe, the shadow consisting of a line of clear glass upon which no copper has been deposited. In Swan lamps which I have had the opportunity of observing (and there are several here on the table for your inspection) I have never seen such a shadow in either the carbon or the platinum deposit.

My son, Mr. Charles Proctor, who is electrical engineer at the Swan Works, at Benwell, informs me that these carbon deposits which occur when a lamp is overheated occur even more in lamps with the highest *vacua* than in those less perfectly exhausted. This would rather discourage the idea of the molecules being carried by currents in the residual air, and as yet we are wanting in evidence of the molecules being thrown off in radiations, and equally wanting in any indication of the carbon having been in a truly gaseous condition.

As the highest temperature to which the carbon can be raised fails to give any appearance of softening, I think we must give up any idea of the bending noted in 1878 being consequent upon an incipient plasticity; and if the smoky deposit is supposed to be the result of vaporized carbon we may also suppose that it cannot be melted except under the combined action of heat and pressure.

Several lamps on the table illustrate the condition of the smoky deposit. There are four in which the deposit has accompanied the formation of an arc, and four in which the arc has not been formed, or the current has been stopped at the moment of its formation. In none of them can any symptom be observed which would indicate such a radial projection of molecules as to throw a shadow of the filament on the opposite side of the globe. There are also two broken globes, in one of which you may notice a patch of the deposit has been burned off by the heat of a spirit lamp, showing that the deposit is almost entirely carbon. In the other fragments the purple-black tint shows that an arc had formed by fracture close to the platinum wire, scattering platinum upon the glass almost free from carbon, as the film is little affected by heat, and almost entirely removed by *aqua regia*. These deposits have all been formed intentionally by passing through the lamps stronger currents than they were intended to carry.

AMERICAN DRUGS.*

BY J. MOELLER,

Botanist and Microscopist of the Imperial Forest Institute, Mariabrunn, near Vienna.

The Americans are eagerly investigating their indigenous flora for substitutes for the drugs of the old world. Their endeavour toward an independent materia medica is, without question, perfectly proper, and should they occasionally in this endeavour overshoot their mark (a something which the American nature is prone to do), it should not be forgotten that our knowledge of the remedial properties of our drugs was not achieved at one stroke, but that we are indebted for it to the experience of a thousand years.

It is very unjust, in my opinion, to regard with suspicion, as is generally done, everything bearing American endorsement; a previous thorough investigation would seem to be a matter of justice. If several of the American drugs which have of late years been heralded as specifics have not fulfilled the promises made for them, a remembrance on the other hand of our experience with several preparations of European origin and endorsement will move us to forbearance. In this manner the sanguine expectations aroused by extravagant claims have a good effect; the whole world is stimulated, and even impelled, by them to give the drug a trial, and in a short time judgment is passed on it. In a few weeks the excitement is past, and not unfrequently we have as a result an acquisition to our medical treasures, as, for instance, in the case of cundurango and salicylic acid. Such discoveries are, it is true, not made every year, but, it seems to me, that the least important and even the most insignificant are worthy of cognizance.

The well-known house of Parke, Davis and Co., of Detroit, Michigan, U.S., have most obligingly furnished me, for experiment, samples of the crude drugs from which their widely-known pharmaceutical preparations are made. These samples form the basis of the following descriptions:—

I. CORTEX RHAMNI PURSHIANÆ (CASCARA SAGRADA).

Convex or quill-shaped pieces of bark, three finger-breadths or more in width, and something over 2 mm. in thickness, violet-brown and smooth on the exterior surface, and Morocco yellow and finely wrinkled on the inner surface. In the older, superficially grooved specimens the thin corky, brownish layer peels off in places from the ochre-yellow net-like base; in the younger, occasionally quill-shaped bark, the superior surface is broken up into irregular divisions—a finger-breadth apart, pointed at both ends and about 1 mm. in width at the middle.

The bark breaks with a short fracture; the external broken surface is smooth; on the internal the greater part is thickly studded with very delicate brush-like fibres of at most 1 mm. in length. To the unaided eye the diagonal incision appears nearly homogeneous. Under the lens one sees dispersed on the outer part bright spots, in the bast radiant streaks, with irregularly disposed diagonal lines between them.

Microscopical Structure.—The cork membrane numbers in a thickness of 0·045 mm. from 8 to 12 series of regular smooth somewhat thick-walled but never sclerotic cells, and borders directly on the tangentially disposed primary bark, which here and there maintains

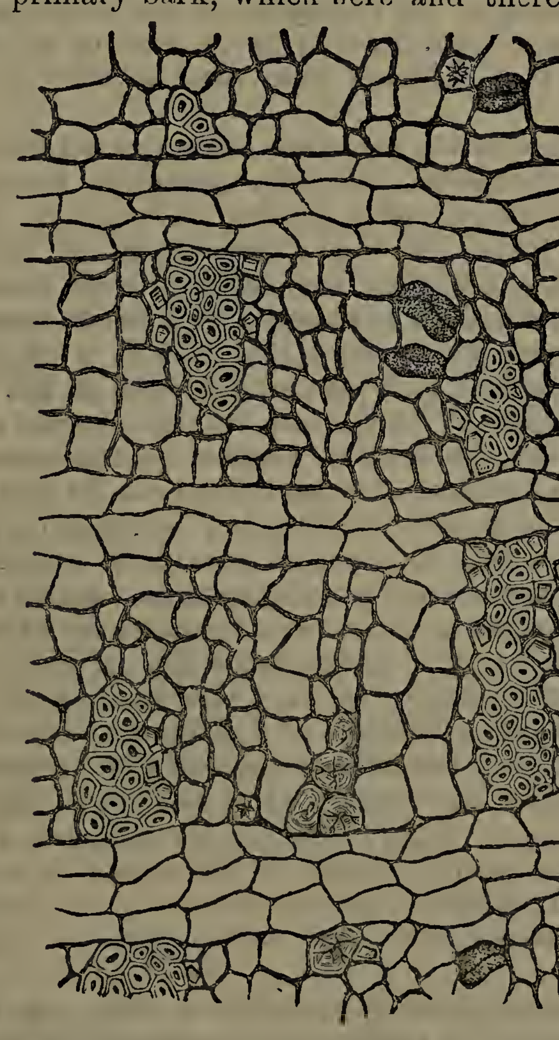

Fig. 1.—Transverse section through the bast layer.

a collenchymatic character. There is no cork. In the parenchyma of the bark are found, scattered irregularly,

* Reprinted from the *Therapeutic Gazette* and translated from the *Pharmaceutische Centralhalle*, 1882, Nos. 28, 31 and 33. We are indebted to the courtesy of Messrs. Parke, Davies and Co., of Detroit, for *clichés* of the original engravings illustrating this series of articles.

groups of spherical stone cells (up to 0·4 mm. in diameter), whose elements are not increased, which are thickly disposed and which are accompanied by individual rhomboidal crystals while in the thin-walled parenchyma crystalline glands predominate. The inner bark (Fig. 1) is usually separated into two or three divisions of very uniform breadth by the medullary rays. These consist chiefly of soft bast in which the ethmoidal tubes are distinguishable on cross section from the narrower and rounded parenchyma cells by their wider and irregular lumen. The ethmoidal tubes are connected by several (4–6) wide sieve-plates of quite porous structure and covered with a thick callus in the young bast layers; on the radial lateral surfaces they have rounded sieve fields. The parenchyma cells are coarsely spotted on the radial and horizontal surfaces, and in a tangential direction they are loosely united and partially separated. The bast fibres form small plates usually of two or three rows which extend over only a few bast rays and are disposed alternately among the neighbouring plates. They are surrounded on all sides by chamber fibres with separate crystals, while the bast parenchyma has but a few glands.

Groups of stone cells similar to those found in the middle bark are rarely found in the bast. The radiations of the medulla are very slight and consist of thin walls between the bast fibres. They contain no crystals but have instead a friable, lemon-yellow substance (rhamnoxanthin ?) which dissolves in water with a yellow, but which when dissolved in cold potassa lye assumes a dirty red colour. Starch is absent from all parts of the bark.

Cascara sagrada differs very clearly from the "cortex frangulæ" which is officinal in the German, Norwegian, Swedish, Danish and Russian pharmacopœias, in the thickness and fragility of the bark, the frangula bark being at most 1 mm. in thickness and of a tough fibrous nature. An excellent distinctive feature of the American variety is the groups of stone cells found in the middle bark and sparingly in the bast. These were also found to be absent in other varieties of *Rhamnus* examined by me (see J. Moeller, 'Anatomie der Baumrinden,' Berlin, 1882). It is also noteworthy that there is a hardening of the radiations of the medulla between the groups of bast fibre, as in the case of the *Rhamnus tinctorius*, thus differing from most of the other Rhamnaceæ.

The source of the cascara sagrada (sacred bark) is the *Rhamnus Purshiana*, DC. (*Rh. alnifolius*, Pursh., *Frangula Purshiana*, Cooper), a shrub or tree 7 m. in height, which is found on the Pacific slope of the United States. Its branches are covered with down. The leaves are elliptical in shape, 5 to 8 cm. in length and 3 to 8 cm. in width, having a leaf stalk of 2 cm. in length, blunt at the base, pointed and dentated at the margins. When young the leaves are thickly covered with hair, but later become smooth, similar to the leaves of the *Frangula Caroliniana*, Gray, indigenous to the southern states. The flowers are disposed in dense corymbs, are small and white, and develop into black triangular fruit the size of a pea, each containing three shining seeds.

Cascara sagrada seems to be identical with Chittem or Shittem bark, under which name Ed. A. Mayer learned as early as 1850 that the bark was used by the Indians and trappers of California as a cathartic. More recently it has been very extensively employed in America, where it is regarded very highly as a remedy in constipation and dyspepsia. Dr. J. R. Boyd, for instance, regards it as being as nearly specific in its action as quinine (!) and finds in addition that as a remedy in chronic constipation small doses are more beneficial than large doses.

Two preparations manufactured from the bark are almost exclusively employed: an alcoholic extract and an elixir, made with dilute alcohol and glycerin, and the oils of orange and cinnamon, etc. A formula for the preparation of these was submitted by George W. Kennedy to the American Pharmaceutical Association (reprinted in the *Druggists' Circular and Chemical Gazette*, August, 1881, and in the *Pharmaceutical Journal and Transactions*, September, 1881). Complaints are already made of the existence of false varieties in the market. In the March, 1882, number of the *Therapeutic Gazette*, it is stated that owing to the ignorance of the drug-gatherers a large quantity of worthless and inert bark of other varieties has been placed on the market.

(*To be continued.*)

CALIFORNIA OLIVE OIL.*

Adjoining the Hollister place is the 2000 acre ranch of Mr. Ellwood Cooper, which is the model country place and fruit farm. It is almost unnecessary to rehearse the statistics of the 150,000 eucalyptus trees of fifty different varieties, the 12,500 almond trees, the 4000 walnut, the 3500 olive, the 200 fig, the 200 vine, and the odd hundreds of other fruits. Mr. Cooper was the first to introduce the eucalyptus tree to California, and has seven miles of windrows and shade trees of this one species on his place. A greater distinction has come to him in the last few years, as the first one in this country to engage in the manufacture of olive oil from olives. Don Josef de Galves brought the first olive slip to California in 1769, and around all of the old Franciscan missions are groves and remnants of olive groves that sprang from those original cuttings. Mr. Cooper planted his first olive slips in 1873, and he has now a fine grove in full bearing, although the trees are mere saplings in point of age to some of the century-old olive trees in Italy and the south of France. To the inexperienced an olive tree looks very much like a willow tree, save that the leaf is darker and the under side of it is of silvery white, that shows with beautiful effect when stirred by the wind. Botanically it belongs to the jasmine family; has an evergreen foliage; produces fruit in seven years when grown from the seed, and in four years when grown from a cutting. It blooms about the first of May, and the fruit ripens from November to January. The olives for picking are gathered in September or October, before they are fully ripened, and put to their bath of wine, and the oil is made in mid-winter.

The oil is made in a wooden building at the back of the residence house, and the exquisite neatness and cleanliness of the place is even accented by frequent signs warning off all smokers and tobacco scented people. So particular is Mr. Cooper that he employs no one at the oil works who uses tobacco in any form, and everything is done to prevent the delicate article from absorbing any taint or odour. The oil works are kept dark and cool, and at this season are closed and barred. There are great pans where the olives are first shovelled in and crushed under two revolving stone wheels. Following that, the pulp is thrown into tanks, pressed, allowed to settle, and then skimmed off, strained three times through cloth, once through paper, and finally bottled. The first quality of the oil is put up in long quart bottles bearing the maker's name on cork and glass. Very little of the second quality oil, resulting from the second pressing of the pulp, is made; but when it is prepared for the market it is put up in pint bottles and duly labelled as second quality.

As to the profits to be realized from olive oil after the first ten years, one has only to count up the facts to be gathered on the Cooper place. The olives are planted with seventy trees to the acre. The average yield of one tree in a good year is twenty gallons of olives, from which three gallons of oil are made. The oil is sold at wholesale at 1 dollar for each quart bottle, and counting at this rate an acre of olive trees ten years old will give 800 dollars clear returns in oil. During this last winter 14,000 bottles of oil were made on the Cooper place.

THE FUTURE OF CINCHONA CULTIVATION.

WE have just received a copy of an official report upon the Government cinchona plantations in the Nilgiris which promises to mark an epoch in the history of cinchona cultivation. It is from the pen of Dr. TRIMEN, formerly of the British Museum and now Director of the Royal Botanical Gardens, Peradeniya, Ceylon, who in complying with a request that he would inspect and report upon the "botanical problems" presented by the Nilgiri Cinchona Plantations has introduced passages that will ruffle the complacency of more than one "authority" and no doubt provoke "official" replies. In fact Dr. TRIMEN's description of the botanical aspect of the Madras plantations is not surcharged with *couleur de rose*, and appears to show that the measure of success which has attended this grand experiment in acclimatization has been attained in spite of numberless mistakes, involving the nomenclature of the different varieties or species of cinchona under cultivation in an almost inextricable confusion. Some suspicion of the existence of such a state of things has probably passed through the minds of those who have followed the literature of the subject even so far as it has appeared in these pages, but few would have anticipated there were so many and wide differences of opinion respecting the botanical identity of the plants grown as are disclosed in this report. Dr. TRIMEN's opinion of the situation may be gathered from a remark with regard to some of the best-known writers upon the subject, that whilst recognizing the many and great services they have rendered to the cinchona enterprise, yet, as a botanist, he thinks it much to be regretted that circumstances should have thrown this very difficult genus into the hands of those who have had so little of the requisite training and experience in systematic botany for dealing with it effectively. He considers it ought to be generally understood that "however eminent a writer may be as a quinologist, "a traveller or a gardener, if he can see important "botanical characters in the height of a tree, the "chemical constitution of its bark, or the colour of "its leaves, he is *ipso facto* disqualified to pronounce "on questions of classification." A number of published names have, however, Dr. TRIMEN says, been defined by nothing more than some such botanically trifling or variable distinctions and should not be recognized until properly characterized, since there is nothing about the genus *Cinchona* in its botanical aspects to warrant it being treated on any principles differing from those the systematist is ordinarily accustomed to employ, and for authors who know little of these principles or have had no experience in the application of them to other groups of plants to attempt to arrange the forms of so involved and complicated a genus can only lead to failure and confusion.

It would be almost impossible, as indeed it would be useless, to compress within reasonable limits in these columns an intelligible *résumé* of the elaborate criticism by Dr. TRIMEN upon the nomenclature which obtains in the cinchona plantations in Southern India. It is more satisfactory to be able to say that in reading this report one becomes impressed with the fact that the writer has a good grip of a most perplexing subject, and that whether he succeeds or not in establishing all his contentions his evident thoroughness is an element in favour of the evolution of order from the present confusion. Few will feel disposed to oppose his plea for uniformity, or to dispute that it is desirable that the same plants should bear the same names in India and Ceylon and elsewhere, and that obsolete, incorrect or duplicate names should be abandoned. As an instance of the necessity for reform, it is stated that in the Dodabetta plantation alone no less than three different cinchonas are called "crispa," whilst the one of the three to which it is rightly applied is so ill-defined that the name might well be dropped altogether. Moreover, there appear to be several names applied to real or supposed hybrids that might be dispensed with as incorrect or misleading.

So far Dr. TRIMEN speaks as a botanist, and it must be admitted that one essential to the resolution of the existing chaos into order is the authoritative determination of the botanical nomenclature of the cultivated cinchonas. Such determination would be to the cinchona grower a great boon, as facilitating his acquisition or avoidance of certain kinds. But this is not all. As long as two or three names are applicable to one and the same plant, or as many different plants are included under one name, any general deductions drawn from comparison of experimental results would probably only be misleading; but when a distinct understanding has been arrived at as to the exact species or varieties that are to be considered to be indicated by particular names, equally in other countries as in India, the way will be cleared for more satisfactory investigations. As pointed out by Dr. TRIMEN, the range of difference in the proportions and quantities of the alkaloids in barks from trees of identical botanical type is very large, and the same is true of barks from different plants raised from the seeds of the same tree. Barks from plants having their origin in cuttings from one and the same tree also yield different results upon analysis, although it is known that the stock has no influence on the grafted shoots; even the cause of the increase of alkaloids in renewed bark is but little understood, and the influence of age upon alkaloidal composition in the various species can only be guessed at from experience. Dr. TRIMEN, therefore, urges that the recent appointment of a distinguished botanist as superintendent of these plantations may be supplemented by the appointment of a chemist, whose duty it shall be to assist in working out these most important problems. Dr. TRIMEN is of opinion that the chemist must be on the spot among the trees constantly and always in readiness to work in unison with the superintendent as one man at jointly planned investigations, and it must be admitted that there is much reason for the view he takes. At the same time it is, however, to be borne in mind that if the chemist entrusted with these duties is to render any real service he must possess, not merely a general acquaintance with the chemistry of cinchona alkaloids, but a thoroughly practical familiarity with this special and difficult branch of analysis. It may not be easy to provide at once for such work being carried on at the spot, but it is a matter of such importance as to merit consideration how it can best be done at the earliest possible time. Since the sudden resignation and disappearance of Mr. BROUGHTON, eight years ago, little, if any, chemical investigation has been carried on in connection with the Madras plantations; but we think this work might now be advantageously revived, on the lines recommended in this report. After all it is not the propagation of any particular species of *Cinchona* or the supply of large quantities of bark that is the ultimate object of these experimental plantations; but rather the working out of the conditions most favourable to the production of the febrifuge alkaloids. In the present state of our knowledge, the most promising method for the improvement of cinchona trees as alkaloid yielders appears to be selection in cultivation based on chemical analysis. This Dr. TRIMEN proposes to effect by the isolation of trees that yield barks giving upon analysis high proportions of the more valuable alkaloids, the taking of proper precautions to prevent cross-fertilization, the exercise of care in collecting seed, the analysis of bark from a selection of the resulting plants, the destruction of all the young plants that do not reach the standard of the parent plants, the isolation of the best of the progeny, and the repetition of this process for several generations.

It may be hoped that this view of the case will commend itself to the judgment of the Indian Government, as being consistent with the policy which first prompted the establishment of the plantations; for there is more than a suggestion in the present report that the scientific and experimental phase of the undertaking has, since the death of Mr. McIVOR, been somewhat eclipsed by more commercial aspirations, and that indeed the plantations have recently been overworked for the sake of obtaining large returns of bark. However this may be, it has now been sufficiently demonstrated that cinchona cultivation may be carried on remuneratively, and that even from a commercial point of view the State cinchona plantations have been a profitable investment. But the production of bark for the sake of money gain only may well be left to private enterprise, and there would be a fitness in devoting the resources of the establishment in Madras, where the great acclimatization experiment was initiated, primarily to scientific investigation having for its object to obtain the results most beneficial to humanity. In conclusion, we would heartily endorse the recommendation of Dr. TRIMEN that the Government should take care to secure an accurate record of all the experimental work carried on, whether in the plantations or the laboratory, and that the results should be promptly made available to the public in annual reports, which ought also to be easily obtainable by any person wishing to refer to them, and not confined to officials and a favoured few among outsiders.

THE PROPOSED HEALTH EXHIBITION.

THE definite appointment of an Executive and a General Committee, charged with the duty of making the necessary arrangements for holding an International Health Exhibition next year at South Kensington, has been backed up by a donation of ten thousand pounds from the Corporation of London and the city guilds, with a promise of further monetary help if required, so that it is now morally certain that the enterprise hinted at by his H.R.H. the Prince of Wales when closing the Fisheries Exhibition will be an event of the year 1884. The term "Health" will be very inclusive, since it is intended that all applications of modern science and improved sanitary practice to dwellings and workshops and to food and dress shall be illustrated as far as possible, and the display must therefore necessarily touch at several points subjects that are of great interest to pharmacists. The collections of substances used as food in different parts of the world, for instance, and also illustrations of food adulteration, if given with discretion, will be almost sure to furnish valuable contributions to that *omnium gatherum* of information which every pharmacist is presumed by the public to possess. The same remark will apply to many sanitary contrivances concerning the merits of which he is not unfrequently asked to express an opinion. Further, just as medicine is well represented upon the Executive Committee, drugs and medicinal preparations are not likely to be few. Whatever may be the general effect, however, of the exhibition in promoting the health of the community, we cannot say that we are very sanguine as to the exhibition exercising any particularly beneficial influence upon the practice of pure pharmacy. It seems to have become a recognized practice in connection with all such undertakings that the exhibitors shall be allowed to recoup themselves partially for expenditure consequent upon the display of their goods by presenting these to the public accompanied with the exhibitors' own accounts of their virtues. With many classes of goods any disadvantages attending this practice stand some chance of being rectified by the opportunities afforded, by inspection, of forming a correct judgment as to the trustworthiness of the recommendations; but, unfortunately, with respect to substances or preparations put forward as medicines, this is notoriously not the case. The occasion will be so favourable for the display of specialties and proprietary preparations under an appearance of authoritative sanction that it is not likely to be neglected, and even if an arrangement be made to exercise some control as to the articles that are allowed to be shown, the task will be an extremely difficult one. But of this we see no sign, and in the absence of such a provision, the specialists and quacks will have this part of the field to themselves.

On Monday next, in accordance with notice, the election of six annuitants on the Benevolent Fund will take place, in the House of the Pharmaceutical Society, 17, Bloomsbury Square. Although the number of candidates in excess of those to be elected is small, the work of going through so large a number of voting papers will be heavy; the services of a considerable number of scrutineers will therefore be desirable, whilst the attendance at the formal meeting is usually small. We think we need only mention this difficulty to ensure the necessary help, and we think it should be understood that any subscriber or donor to the fund who is entitled to vote at the election is also eligible to act as a scrutineer, whether he be a member of the Pharmaceutical Society or not. Whilst writing upon the subject, we cannot help referring with regret to the fact that was mentioned at the meeting of the Council last week that the receipts on behalf of the Benevolent Fund were at that time at least six hundred pounds less than those of last year.

* * *

The next Evening Meeting of the North British Branch of the Pharmaceutical Society will be held in the Society's Rooms, 119A, George Street, Edinburgh, on Wednesday, the 19th inst., when papers will be read entitled, "Solubility of Calcic Hydrate at Different Temperatures," by Mr. T. Maben; "Salicylate of Soda," by Dr. Stevenson Macadam, and "Hippurate of Soda," by Mr. Peter Boa. The chair will be taken at half-past eight o'clock.

* * *

During a discussion at a recent meeting of the Dimbula Planters' Association, in Ceylon, some astonishing statements were made with respect to the effect of "shaving" the bark of cinchona plants upon the yield of alkaloids. A Mr. Paterson, giving his experience with trees eleven years old, stated that the original shaving yielded equal to 1·96 per cent. of quinine sulphate; the first renewal, 5·76 per cent.; and the second renewal, 7·05 per cent. This planter, however, recommends that the trees should not be shaved more frequently than once a year; but other speakers were of opinion that the operation might be effected advantageously at shorter intervals, and one stated that he had found it answer to shave trees of from three to five years old and that by leaving alternate strips he expected to be able to shave them every three months. A Sub-Committee was appointed to draw up a report on cinchona culture in the district.

* * *

An attempt is being made, with some prospect of success, to introduce the cultivation of cinchonas into the North Island of New Zealand. The planter who has initiated the experiment, and who formerly had charge of a large cinchona plantation in India, commenced operations last year, and he states that he has already raised upwards of three quarters of a million seedlings, a considerable proportion of which have been sold to other planters at remunerative prices.

* * *

According to a quinquennial report recently presented by the French Minister of Commerce the number of *pharmaciens* in France increased from 6232 in the year 1876 to 6443 in 1881.

* * *

The *Bulletin de la Société de Pharmacie de Sud-Ouest* records a case of poisoning that occurred recently in Toulouse, in which the assumption that morphia was the poison gave rise to a newspaper hubbub about the carelessness of pharmacists in supplying poisons of a kind not unknown in this country. A legal inquiry having been instituted, however, the results of the analysis of the stomach, etc., taken in conjunction with the physiological symptoms observed, led to the conclusion that death had been caused by nicotine.

* * *

Her Majesty's Consul at Charleston, referring in a recent report to the adulteration of oil of turpentine with petroleum products in different proportions, says that the admixture of 10 per cent. of "petroleum benzine" is the form that appears to be the most successful, since a sample of oil of turpentine so sophisticated cannot be distinguished by the eye or nose from a genuine one. As to the method of examining oil of turpentine for such an adulteration, reference may be made to the paper by Dr. Armstrong (*Pharm. Journ.*, [3], xiii., 584).

* * *

Her Majesty has been pleased to confer the honour of a baronetcy upon Mr. William Bowman, F.R.S, and upon Mr. Joseph Lister, F.R.S.

* * *

The next meeting of the Chemical Society will be held on Thursday, December 20, at 8 p.m., when papers will be read on the "Researches on the Constitution of the Gums of the Arabin Class," by Mr. C. O'Sullivan; "On the Decomposition of Ammonia by Heat," by Messrs. Ramsay and Young; and "On the Dissociation of the Halogen Compounds of Selenium," by Messrs. Ramsay and Evans.

* * *

A meeting of the School of Pharmacy Students' Association will be held on Thursday next, December 20, at 8 p.m. A paper upon "The Relation of Pharmacy to Therapeutics," will be read by Mr. R. W. Giles, and the Reporter upon Materia Medica, Mr. W. Elborne, will make a communication upon "Munjeet in Chiretta."

Pharmaceutical Society of Ireland.

MEETING OF THE COUNCIL.

The monthly meeting of the Council was held on Wednesday, December 5; the President, Mr. James E. Brunker in the chair.

Present:—The Vice-President, Mr. H. N. Draper, F.C.S.; Drs. Collins, Montgomery; Professor Tichborne, Ph.D.; Messrs. Allen, Doran, John Evans, Grindley, Hayes, Hodgson, Minchin, Payne, Simpson and Wells.

The Registrar read the minutes of the last meeting which were confirmed.

The Registrar read a letter from Right Hon. G. O. Trevelyan, the Chief Secretary for Ireland, stating that he had received the letter of the Registrar stating that a deputation from the Council desired an interview with him in reference to some points connected with the state of the law as to pharmacy and the sale of poisons in Ireland. He would be going to Scotland in a few days; and after his return, if the Council communicated with him, he would arrange as to the day on which he would receive a deputation from them.

The President suggested that a deputation should be named now.

Mr. Grindley: I do not think it should be confined to one or two. As many of the Council ought to attend as can.

Mr. Payne: Some representative men on both sides of the question would be better than a very large deputation.

The President: If there be any difference of opinion it should be argued at the Council table. We must decide on what we want here. Everything that we want has already gone before Mr. Trevelyan in writing.

Mr. Hodgson said the feeling seemed to be that it should be open to every member of the Council to go on the deputation.

Dr. Collins said that was the course pursued in a late deputation from the Apothecaries' Hall. If there were any differences of opinion these had better be settled now.

Mr. Wells: The only point on which we differ is as to whether there should be a second grade or not.

Mr. Hayes said that outside the Society there was a desire amongst chemists and druggists to be registered in order to prevent the continuance of a practice which was evidently intended to be prevented by their Act, namely, the sale of poisons without hindrance by new chemists and druggists who were continually springing up.

Mr. Wells said they were all agreed that only registered men should be allowed to sell poisons; but there was a difference of opinion as to the establishment of a second grade, which would be perpetuated.

Mr. Minchin observed that the establishment of a second grade would not affect members of the Society who carried on business in the metropolis, but it would be ruinous to those in the country to have the legitimate drug trade and sale of poisons taken out of their hands, because in the country towns the prescriptions of medical practitioners would not anything like suffice to maintain the pharmacists.

Mr. Hodgson: This discussion is out of order. If we are to discuss these matters at all we must have a special meeting for the purpose.

The President: The only question at present before us is whether a special deputation should be appointed, or the entire Council should attend. I think it better now for us to pass to the next business with the understanding that in case Mr. Trevelyan decides on receiving the deputation before the January meeting a special meeting will be called. The question must then be settled whether it is the wish of the majority of the Council that a grade of registered druggists should be made perpetual or not. The Council of last year expressed an opinion that such a grade might with advantage be introduced.

A letter dated November 12 was read from Mr. James Leahy, of Clonmel, asking for exemption from the course of practical chemistry, on the ground that he had been for eighteen years at the business of compounding.

Mr. Payne moved—

"That Mr. Leahy be informed that the Council cannot see its way to departing from the rule laid down respecting a certificate of having attended a course of practical chemistry."

Mr. Allen seconded the motion, which was agreed to.

The President said a letter had been received from Mr. Hardy which was not on the notice paper. If the Council desired, it could be read; but it merely urged points in reference to which they were still awaiting a communication from the Solicitor-General, and therefore were not prepared to give any decided answer.

Mr. Wells: I do not think there would be any use in reading the letter.

The Registrar was directed to inform Mr. Hardy that no reply had as yet been received from the Solicitor-General.

On the motion of Mr. Minchin, seconded by Mr. Payne, the four gentlemen who had acted as examiners for the past year were re-elected.

Dr. Montgomery remarked that he thought the gentlemen who were appointed by the Council to attend as visitors at the examinations should hold a more prominent part than they did. They were in a curious position; they seemed to have no voice in the examination, and from what occurred last day he thought it would be well if their duties were defined.

The President: You will have to give notice of a motion in order to discuss that.

Mr. Draper: It could be put in the agenda for the next meeting.

Notice of motion was handed in by Dr. Montgomery on this subject.

A letter was read from Dr. Kaye, Q.C., Clerk to the Privy Council, enclosing a copy of a memorial which the Privy Council had received in reference to the proposed new regulations of the Society which are at present under the consideration of the Lord Lieutenant and Privy Council, and saying that in the event of the Council deeming it expedient to comply with the prayer of the memorial it would be necessary to re-submit the proposed resolution, in an amended form. The memorialists stated that they had passed the Preliminary examination; that according to a resolution of the Society, published in the 'Calendar,' for 1883, candidates were eligible for the final examination who had been practically engaged in compounding and dispensing for two years in the establishment of a pharmaceutical chemist or apothecary keeping open shop; that a new regulation had been adopted, but not yet sanctioned by the Privy Council, enlarging the period to four years, and that it was proposed to give that regulation a retrospective effect from January, 1883; that the memorialists and many others similarly circumstanced had been induced by the regulation at present in force to enter on the study of the profession in the belief that a period of only two years' service in compounding and dispensing would be required; that they would be most unfairly and injuriously affected if the Privy Council sanctioned the making retrospective of the new rule requiring four years' service; and they, therefore, prayed the Privy Council to amend the resolution so as to prevent the rule from having any retrospective effect.

The Law Committee in reference to the foregoing letter and memorial, which had been considered by them, recommended that the resolution in question should be amended so that the new rule should not come into force until January 1, 1884.

The President observed that the resolution establishing the new rule as to apprenticeship was adopted by the Council last January. It was sent to the Privy Council and was returned by them in an elaborate form last April to the Council of the Society and was, after due consideration, accepted by the latter on June 6, and returned to the Privy Council for confirmation; and since then the whole matter had lain in abeyance. The memorialists had gone in for and passed the Preliminary examination practically under the old bye-law, which was the one printed in the Calendar for the present year. The communication from Dr. Kaye gave a very strong hint that what these gentlemen asked for was only reasonable. The recommendation of the Law Committee was that the Privy Council should be asked further to amend the resolution so as to bring the new rule into force from January 1, next.

Mr. Grindley: We are not in a position to refuse this memorial.

After some further discussion—

Professor Tichborne moved that the recommendation of the Law Committee in relation to the communication received from the Privy Council be adopted.

Mr. Doran seconded the motion, which was agreed to *nem. con.*

On the motion of Mr. Wells, seconded by Mr. Grindley, the rest of the report of the Law Committee was adopted.

Mr. Grindley observed that all the members of the House Committee had not been summoned to its recent meeting.

The President explained that the Committee had not met since last Council meeting. The intention in placing the matter on the notice paper was to settle the question of office hours.

Mr. Draper said that technically Mr. Grindley was right, but practically the business of the Committee had been done by a few members who put their shoulders to the wheel and worked very satisfactorily.

Mr. Payne said the work of the House Committee had been splendidly carried out.

The President said it was necessary to make a regulation as to the days and hours at which the Registrar, Mr. Fennell, should attend at the Society's rooms.

After a brief discussion,

On the motion of Mr. Hayes, seconded by Dr. Collins, it was resolved—

"That the Registrar should attend at the rooms, 11, Harcourt Street, on Mondays, Wednesdays and Fridays, from 10 to 12 o'clock noon, and that notification of this rule be placed on the door-plate."

The following gentlemen passed the examination for the licence as pharmaceutical chemist, held on October 3 and 4, and were registered as pharmaceutical chemists on November 7:—Messrs. Robert Carse, Dungannon; Robert Duggan, Rathmines, Dublin; Thomas Johnstone, Belfast; Patrick Kelly, Dublin; Alfred McBride, Dundalk; Robert William McKnight, Belfast; Patrick Merrin, Dublin; and Henry O'Reilly, Dublin.

The following licentiates were elected Members of the Society:—Henry Conyngham, 11, Upper Baggot Street, Dublin; John Starrett Shortt, Kells, co. Meath; John Dillon Crinion, 67, Talbot Street, Dublin.

The Council then adjourned.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The fourth general meeting of the thirty-fifth session was held at the Royal Institution, on Thursday evening, November 22; the President, Mr. Edward Davies, F.C.S., F.I.C., in the chair.

The minutes of the previous meeting were read and confirmed, and the following donations were announced:—The *Pharmaceutical Journal*, from the Society; and the *Canadian Pharmaceutical Journal*, from the Editor.

Mr. A. H. Mason exhibited pieces of granite faced with powdered rhubarb, which he had found as an adulterant in some original cases of East India rhubarb root as imported. The fraud was so well perpetrated that the miller failed to detect the pieces of stone when the root was placed in the drying-room before powdering, the size and shape of pieces resembling that of the root. The adulteration represented 2 per cent. of the bulk.

Dr. Symes presented to the Museum a specimen of pao-pereiro (*Geissospermum Vellosi*), used in Brazil as a tonic and febrifuge, intensely bitter and containing an alkaloid "geissospermine." He also exhibited a specimen of Batata de purga, or Brazilian jalap (*Piptostegia Pisonis*) tuber, 8 inches long and 3 inches in diameter, used as an aperient in Brazil; its activity being dependent on a resin which is readily extracted by alcohol.

Mr. Davies exhibited a specimen of urine passed by a person recovering from carbolic acid poisoning. It was dark, almost black in colour, and on distillation with sulphuric acid gave a distillate containing both phenol and cresol. There was a distinct smell of phenol in the distillate; it gave the reaction with ammonia and hypochlorite of sodium, and bromine gave an abundant precipitate of tribromophenol (recognized by its crystalline form) and tribromocresol. If distilled without sulphuric acid only a trace of phenol was found, and also when an attempt was made to extract it with ether. It is, therefore, thought probable that the phenol and cresol were in some form of combination.

Mr. Parkinson drew attention to some tinct. opii he had recently made, which after the usual period of maceration would not give a clear filtrate. He had tried various thicknesses of filtering paper, but to no effect. He said the opium was obtained from a most respectable house, costing a fair price, and of apparently good quality.

Mr. Conroy said that he had met with one or two samples of such opium. The difficulty experienced was due to the fact that the opium was adulterated with Bassorah gum, and tincture made with such opium would be very deficient in morphia strength.

Dr. Symes thought that Mr. Parkinson must have worked on opium containing a considerable quantity of mucilaginous matter, and that he had used a weak spirit for extracting it. He had once found a specimen of Persian opium, which gave similar results, although it had a higher morphia value. His results led him to believe that under ordinary circumstances a weaker spirit than that ordered in the B.P. for making tinct. opii would be an advantage.

The President then called upon Mr. Michael Conroy, F.C.S., to read a paper on "Tincture of Nux-Vomica."

The paper is printed on p. 461, and gave rise to the following discussion:—

Mr. A. C. Abraham in moving a vote of thanks to Mr. Conroy for his able communication, alluded to the importance of the subject and the great value of the tabulated information placed before the meeting. He confirmed Mr. Conroy with respect to the great difficulty, if not impossibilty, of extracting nux-vomica, when in fine powder, with the menstruum of the British Pharmacopœia. He had obtained from a sample of tincture which he had recently made and carefully extracted 1·08 grains of extract from 100 fl. grains of tincture. This lot, he said, occupied about six days in percolation. He thought that there could be no question that a weaker spirit was required for the purpose and was glad to see that Mr. Conroy nearly agreed with the German and French Pharmacopœias as to the strength required.

Dr. Symes, Ph.D., in seconding the vote of thanks, considered the results obtained by the author of the paper as of very considerable importance. They fully confirmed the position which he had often taken and which he still maintained, namely, that it was absurd for the Pharmacopœia (or its compilers) to assume that all drugs could be properly exhausted by means of the two strengths of spirit contained therein for that purpose.

Mr. Conroy having briefly replied, the motion was put from the chair and carried by acclamation.

EDINBURGH CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

The fourth meeting of the sixth session was held in the Pharmaceutical Society's rooms, 119A, George Street, Edinburgh, on December 5, at 9.15 p.m. Mr. Claude F. Henry, President in the chair.

The minutes of the previous meeting having been read and confirmed, the President called upon Mr. G. R. Fowler to read a paper on "Elementary Chemistry," which was the first of a series intended for the younger members of the Association.

During the course of the paper, the essayist illustrated various points by several successful experiments and diagrams.

The President in moving a vote of thanks to Mr. Fowler, said that the Association could not forget that it was on the suggestion of Mr. Fowler that the series of elementary papers had been arranged, and it was gratifying that he gave practical support to the scheme. The presence of so many apprentices proved that they appreciated the proposal, and he was sure that all would join with him in moving a hearty vote of thanks to Mr. Fowler.

Mr. Aitken seconded the motion, which was heartily accorded.

A discussion followed, in which Messrs. Boa, Crowden, Hill, MacAlley and MacEwan took part, and Mr. Fowler replied.

The Secretary then submitted several queries. To the first of these, viz., "Wanted, a distinctive test for a sulphocarbolate," Mr. MacEwan gave the following:—

The following indications are the most trustworthy proofs of the identity and purity of a sulphocarbolate:—

Negative.

1. The salt should not have the slightest odour of carbolic acid.
2. Alkali and zinc sulphocarbolates should be free from pink coloration.
3. An aqueous solution should not give a precipitate with barium chloride.

Positive.

4. Heated to charring, carbolic acid is vaporized—recognized by its odour. The residue treated with water and filtered should indicate presence of *sulphate* with barium chloride (U.S.P.). (Salicylates so treated give a residue containing *carbonate* only.)
5. An aqueous solution of the salt gives a violet coloration with ferric chloride (U.S.P.) The colour is discharged by an acid or alkali, the latter precipitating the iron as hydrate. The violet coloration is readily obtained with a 1 per mille solution of the salt. (Salicylates also give the coloration, but it is much more intense: moreover, an aqueous solution of a salicylate gives a copious precipitate of salicylic acid on the addition of a mineral acid, whereas a solution of a sulphocarbolate remains clear.)
6. A gram or so of the salt heated with a few c.c. of nitric acid in a test-tube forms a yellow solution, NO_2 being evolved; on diluting with water, yellow crystals (picric acid) separate. Filter or pour off a portion of the clear solution, and it will be found that barium chloride forms a precipitate insoluble in nitric acid. Another portion of the solution may be used for the picrocyanic test, by adding to it a few drops of potassium cyanide solution and ammonia to alkalinity, then boil; the solution becomes blood-red.

Notices of queries for next meeting having been given, the President intimated that it would be held on December 26, when Mr. George Coull, an apprentice member of the Association, will read a paper on "Some of the Gum Resins of the Pharmacopœia." The meeting then adjourned.

NOTTINGHAM AND NOTTS CHEMISTS' ASSOCIATION.

On Friday, November 30, the associates of the above Society were entertained at a *soirée* in their new room, in the Sunday School Union Institute, Shakespeare Street, by the President, Mr. Councillor Fitzhugh, F.C.S., and the Vice-President, Mr. J. Wilford. A majority of the young men were present to do justice to the good things provided both for mind and body. The Council was represented by Messrs. W. H. Butler, A. Smith, C. W. Warriner, M. H. Humphrey, and C. A. Bolton, Hon. Sec. Various specimens of interest to the trade of the chemist were exhibited. Mr. B. Sturges Dodd, Hon. Sec. of the Naturalists' Society, exhibited a splendid collection of typical forms of British marine plants (including many edible species), and also a small but very interesting collection of European shells and minerals. Mr. F. H. Spenser exhibited an apparatus illustrating the various phenomena connected with the sun, earth and moon; also a number of Patterson's zoological charts; Mr. G. Inger, a number of galvanic batteries; Mr. J. H Haywood, electrical apparatus and stereoscopic views; Mr. William Widdowson, a large series of mounted indigenous plants; Professor Clowes, the spectroscope, specimens of crystals and a plate showing the new method of protecting iron by oxidation; Mr. A. Rogers, a microscope and uranium glass, the Society's microscope being shown by Mr. W. H. Parker. A most enjoyable evening was spent, the associates showing their appreciation of the efforts made on their behalf by careful examination of the objects and questions asked upon points they could not quite understand. After a vote of thanks to the gentlemen who had contributed to the enjoyment of the evening, the meeting separated at a late hour.

MIDLAND COUNTIES CHEMISTS' ASSOCIATION.

A meeting of the above Association was held on Wednesday evening, November 28, at 23, Burlington Chambers, New Street, Birmingham. The President, Mr. J. Lucas, in the chair.

The minutes of the previous meeting having been read and confirmed, Mr. A. E. Robinson, F.C.S., read a paper entitled "Michael Faraday: the Man and the Chemist." The lecturer commenced by pointing out the direction scientific research has taken and is taking in the destruction of the barriers existing between any two or more departments of science, and consequently the close scientific relationship existing between the discoveries of Faraday in relation to physical science and the researches of Darwin in connection with natural science. The various phases of Faraday's earlier life were then briefly portrayed,—the blacksmith's son, the bookbinder's errand-boy, the journeyman bookbinder,—and then his desire to escape from trade which he thought vicious and selfish, and to enter into the service of science, under the idea that it made its pursuers amiable and liberal, which induced him at last to take the bold and simple step of writing to Sir Humphrey Davy, expressing his wishes and a hope that if an opportunity came in his way he would favour his views. Davy's reply telling him to "stick to business," as "Science was a harsh mistress," was only the prelude to the ultimate engagement of Faraday as assistant in the laboratory of the Royal Institution, and the next view we have of him is as companion to Sir Humphrey in his continental tour, obtaining a glimpse of his association with the foreign *savants* in some of their investigations. The lecturer then read a few extracts from Faraday's diary and letters (written at this period), with the intention of showing the penetration and descriptive power of the young philosopher. Faraday returned to England about the middle of 1815, and the rapid progress in his self-education for the next five years is witnessed principally in the lectures delivered before the City Philosophical Society. It was here pointed out that Faraday, although doubtless much occupied with his literary productions and his work in connection wich the Royal Institution, yet still found time to prosecute important scientific research. Amongst his numerous papers in the *Quarterly Journal of Science* were briefly noticed his investigations on "Steel and its Alloys," "On Compounds of Chlorine and Carbon," and "On the passage of Gases through Capillary Tubes," the latter research doubtless being the first step on the ladder of the law of gaseous diffusion so extensively elaborated by Professor Graham. The subject matter of that memorable paper on "Fluid Chlorine," read by Faraday before the Royal Society, March 13, 1823, was then discussed at some length, and the great importance of apparently so small insignificant a fact as that of converting a gas into a liquid was shown by its undoubtedly being the preliminary step in the discovery by Faraday, in the condensed gas of the Portable Gas Company, of that now historic substance benzine, a substance both theoretically and commercially speaking of inestimable value. The extreme volatility of these condensed substances, and hence their value in industries requiring the production of artificial cold, was then alluded to and experimentally illustrated. Faraday's election as Fellow of the Royal Society in 1824 and the sad but certain opposition of Sir Humphrey Davy having been commented upon, the lecturer passed on to consider that portion of his life history which decided his choice between the pursuit of wealth and the pursuit of science. The lecturer then briefly described the application of his greatest discoveries—Magneto-electric induction and current electric induction to telephony and electric lighting, and then referred at length to Faraday's researches in electro-chemistry, and his ultimate discovery of the law of electrolysis, which to-day is practically where he left it. Faraday's appointments as Fullerian Professor of Chemistry at the Royal Institution and as Scientific Adviser at Trinity House were then alluded to, and the admiration and regard in which he was held by his scientific contemporaries was illustrated by the degrees, titles and honours which showered in upon him from all quarters of the globe; the enumeration of them, however, being fitly closed with the pathetic refusal to allow himself to be elected president of the Royal Society. Faraday's numerous other researches were not touched upon, they being connected with the phenomena of electricity and magnetism, but the correlation of forces (to completely establish which was the main desire of Faraday's life), was illustrated experimentally, *electricity* evolved from the *chemical action* taking place in a galvanic battery being shown to produce *sound*, *light*, *heat* and *magnetism.*

The paper was illustrated by various experiments and a series of water-colour drawings and engravings.

The President proposed a hearty vote of thanks to Mr. Robinson for his paper; the proposition was ably seconded by Mr. Barclay, and on being put to the meeting was unanimously carried.

OLDHAM CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

On Thursday, November 29, 1883, Mr. C. G. Wood read a paper before the members of the above Association, in their room, Church Institute, on the subject of "The Manufacture and Purification of Iodine."

After giving a short account of the discovery of the element, the essayist described the various processes of the treatment of "kelp," which were well illustrated by diagrams of the various apparatus used. He then described the process of purification by sublimation, noting particularly many important precautions which have to be taken to insure the pure article, and also completeness of the operation.

After the essay Mr. Lees proposed a vote of thanks to Mr. Wood, and remarked upon the advantage of diagrams, as they showed at a glance the meaning of the essayist more clearly than if the apparatus is simply described.

Mr. Swinbourne seconded the vote of thanks, which was passed unanimously.

Mr. A. E. Martin, President, occupied the chair.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A meeting of this Society was held on December 6. Dr. W. H. Perkin, F.R.S., President, in the chair.

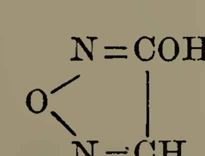
During the evening the following gentlemen were declared by the Scrutators of the ballot, Messrs. A. J. Greenaway and A. K. Miller, duly elected Fellows of the Society:—Messrs. F. A. Blair, T. J. Barr, C. J. Baker, L. Briant, R. G. Durrant, Kamchaudra Datta, L. L. Garbutt, A. E. Harris, T. Hart, W. Irwin, S. Johnson, R. Jackson, H. C. Lee, W. H. Martin, C. E. Potter, B. M. H. Rogers, C. W. Stephens, P. H. Wright, H. A. Wetzel, W. G. Whittam.

The following certificates were read for the first time:—Messrs. B. H. Brough, G. Daubeney, C. C. Hutchinson, W. S. Kilpatrick, E. Matthey, J. W. Pallister, H. Peile, S. G. Rawson, W. Robinson, F. M. Rogers, R. Romanis, W. O. Senior, T. Stenhouse, J. A. Voelcker.

The following papers were read by the Secretary—

On the Constitution of the Fulminates. By E. DIVERS and M. KAWAKITA.—The attention of the authors has been drawn to the chemistry of the fulminates, through the recommendation of mercury fulminate, by Steiners, as a source of pure hydroxyammonium chloride, a fact previously discovered by Carstanjen and Ehrenberg. The authors find that pure hydroxyammonium chloride free from ammonia is obtained by the action of strong hydrochloric acid on moist mercury fulminate, as stated by the above chemists; they find, however, that much hydrocyanic acid is also formed, although not a trace is produced if the fulminate be dry, a theoretical yield of hydroxyammonium chloride being obtained. This substance is strongly acid to litmus paper. The authors ascertained that the whole of the carbon in mercury fulminate, when treated with concentrated hydrochloric acid is converted into formic acid. The authors have utilized this reaction to make an analysis of mercury fulminate, the mercury being precipitated by hydrogen sulphide. They obtained the following numbers:—Mercury, 70·40 per cent.; nitrogen, 9·85 per cent.; carbon, 8·17 per cent. Not a trace of oxalic acid is produced in the above decomposition.

Theory of the Constitution of Fulminates. By E. DIVERS.—After discussing the various formulæ suggested by Berzelius, Kekulé, Armstrong and Steiner, and a lengthy consideration of the formation, decompositions and properties of the fulminates, the author gives the following as the probable constitution of fulminic acid—



On Liebig's Production of Fulminating Silver without the use of Nitric Acid. By E. DIVERS and M. KAWAKITA.—According to Liebig fulminating silver separates in large needles and without ebullition, when nitrous acid is passed into an alcoholic solution of nitrate of silver. The authors have repeated this reaction and obtained crystals, but they consisted of silver nitrate with a trace of some organic silver salt, which is not fulminate. A second experiment, in which silver nitrate and silver nitrite were added to alcohol and nitric acid, sp. gr. 1·35, then dropped in with shaking, also gave no fulminate. The authors conclude that even nascent nitrous acid, alcohol and a silver salt, do not yield a fulminate, but that an energetic oxidation of the alcohol by a mixture of nitric acid and either mercury or silver nitrate alone seems to be effective. The paper concludes with an account of some unsuccessful attempts to form fulminating copper.

Dr. Armstrong then read a short note—

On the Constitution of the Fulminates. By H. E. ARMSTRONG.—In this note the author defends his previous views as to the constitution of fulminic acid, or rather a slight modification of them (HO.N)C.C.H(NO), against the criticisms of Dr. Divers in the previous paper, and briefly considers the probable nature of the reaction between alcohol, nitric acid and mercury. It is not probable that the fulminate is the immediate product of the action of nitrous acid (this note was written before the last paper of Divers and Kawakita was received) upon alcohol, and it is almost certain that alcohol when treated with dilute alcohol has its atoms of hydrogen displaced one by one by hydroxyl; thus a body having the constitution $CH_2(OH).CH(OH)_2$ is formed, and this body the author regards as the primary source of the fulminate, which is formed by the simultaneous or perhaps consecutive action of nitrous acid and hydroxylamine.

Dr. Gladstone said it ought to be remembered that the formula of a substance depended to a great extent upon the reactions by which it is produced, and that it was often very difficult to find a formula which expressed all reactions. He should have liked the formula to have expressed more clearly the formation of sulphocyanide and urea by the action of ammonia and hydrogen sulphide.

Dr. Armstrong said it was not possible to express all reactions in all cases, because the products were often not immediate, but formed by secondary decompositions.

The President thought some light might be thrown on the subject by investigating the secondary products of the oxidation of alcohol as to the formation of formic acid. It was very gratifying to receive communications from Japan, where the facilities for research must be small; possibly such communications might serve as a stimulus to chemists at home to give a little more time to research.

The Secretary then read a paper entitled—

Experimental Investigations on the Value of Iron Sulphate as a Manure for certain Crops. By A. B. GRIFFITHS.—In a previous paper (*Chem. Soc. Journ.*, 1883, Abstracts 496) the author gave the results of some experiments as to the effect of iron sulphate on the growth of single plants. In the present paper he gives the results obtained on the large scale on plots of land near Bromsgrove, Worcestershire, with crops of beans and wheat. One plot was treated with commercial crystallized ferrous sulphate, 56 lbs. to the acre, the other was left in its normal state. The total weight of the dry crop (grain and straw) from the plot manured with ferrous sulphate was 5882 lbs., from the normal plot 4487 lbs.; the former yielded 56 bushels of beans, the latter 35 bushels. The ash of the entire plant and of the pods in the plot manured with iron manure contained much more iron and phosphoric acid than those from the normal plot. The beans from the two plots exhibited but little difference in these respects. In the case of the wheat crops, although the iron manure produced much heavier and finer plants, the ashes did not show much difference as to iron and phosphoric acid. The author has also grown some plants in pots, exposing each pot to a different portion of the spectrum. The soil in which they grew contained ferrous sulphate. Those plants growing in the yellow yielded an ash containing 2·5 per cent Fe_2O_3; those in the violet 0·15 per cent. Fe_2O_3.

Mr. Warington said the paper contained many valuable facts, although some of the statements seemed to require modification or further investigation. There seemed to be no doubt that an increase of 21 bushels of beans was obtained by the addition of the ferrous sulphate; the author seemed to have overlooked the fact as to the increase of phosphoric acid, that one crop had many more pods than the other, and so the increase of phosphoric acid was only an increase in the relative number of pods. He was very sceptical as to the occurrence of crystals of ferrous sulphate mentioned in this and the previous paper, in proximity to the chlorophyll granules.

The Society then adjourned to December 20, when a paper, "Researches on the Constitution of the Gums of the Arabin Class," by C. O'Sullivan, will be read.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of this Association was held on Thursday, November 29; Mr. H. G. Greenish, Vice-President, in the chair.

Mr. T. S. Dymond read a paper on "The Preparation of Pure Benzoic Acid from Urine," which is printed on p. 463 of the present number of this Journal.

A discussion followed the reading of the paper, in which the Chairman, Secretary, Dr. Senier, Messrs. Cripps, Job and Short, took part.

The Reporter on Practical Pharmacy, Mr. R. A. Cripps, then made a report on "Tincture Deposits."

A discussion followed, in which the Chairman, Secretary, Dr. Senier, and Messrs. Job, Ranken and Short took part.

It was announced by the Secretary that the Executive Committee had elected the following members as a Committee of Reporters on Science for the ensuing session:—

Pharmacology	Mr. H. G. Greenish. (Chairman).
Practical Pharmacy	Mr. R. A. Cripps.
Botany	Mr. E. Baily.
Materia Medica	Mr. W. Elborne.
Physics	Mr. H. Allen.
Organic Chemistry	Mr. W. R. Dunstan (Secretary).
Inorganic Chemistry	Mr. A. J. G. Lowe.
Analytical Chemistry	Mr. C. Thompson.

A grant from the Research Fund had been made to Mr. T. S. Dymond for investigations connected with the synthesis of uric acid and some of its bye-products.

The meeting then adjourned.

A special general meeting of the Association was held on Tuesday, December 4, Professor Attfield, F.R.S., President, in the chair.

A code of revised rules was submitted by the Executive Committee, which after some discussion of details was adopted.

The Secretary was instructed to send a copy of the revised rules to the Council of the Pharmaceutical Society for its sanction.

CHEMISTS' ASSISTANTS' ASSOCIATION.

At a meeting of the Chemists' Assistants' Association, held November 28, 1883, Mr. Parkinson (President) in the chair, a paper on "Essential Oils, their Derivation and some of their Uses," by Mr. W. A. Wrenn, was read by Mr. J. H. Hartridge.

The author stated that it was his intention to extend his subject over two papers:—First, he would deal with those essential oils which are cultivated in England and which can be more strictly called medicinal; and in the second paper he would treat of those which are more or less aromatic, and perhaps less used in pharmacy. Ol. anethi from *Anethum graveolens* was the first oil mentioned. It was stated that there are two very distinct kinds of dill seeds in the market, although both are regarded as coming from the same species of *Anethum*. The seeds are said to yield about 3·5 per cent. of oil, which when freshly distilled is almost colourless, but on keeping gradually changes to a deep straw colour, and when allowed to oxidize slowly the original odour is almost completely lost. The oil is distilled in England from the seeds when scarcely ripe, about the end of August. The specific gravity varies from ·842 to ·858, the oil which first comes over being about six degrees lighter than the after-product. Ol. anthemidis from *Anthemis nobilis* was next mentioned, attention being drawn to its peculiar greenish colour when fresh. The specific gravity of this oil is ·979 to ·983; the oil becomes lighter on keeping owing to a deposit taking place: its use as an antidote in cases of poisoning by strychnine was noticed. Ol. coriandri, from *Coriandrum sativum*, was alluded to as being used in the syrup of senna; the yield of oil from the seeds is only about ·5 per cent. Ol. carui from *Carum Carui.*—These fruits were stated to yield about 3 to 7 per cent. of oil, having a specific gravity of ·952 to ·966, consisting of two bodies, viz., a thin oil, termed carvol, and a camphor-like body, carvene. Ol. menthæ piperitæ obtained from *Mentha piperita.*—The author here confined himself to oil produced from plants cultivated in England, the number of acres under cultivation in England in 1883 being as follows:—Mitcham and neighbourhood, 250 acres; Cambridgeshire, 200 acres; Market Deeping and neighbourhood, 300 acres; and Hitchin only a few acres. The yield of oil varies according to the dry or wet state of the herb; as a rule the product is from ·2 per cent., and in exceptional cases as high as ·9 per cent. By submitting the oil to a temperature of 20° or 25° C., white needle-shaped crystals, called "peppermint camphor," are produced; these crystals are almost identical with menthol, now so much used as a remedy for neuralgia. The specific gravity of the oil is from ·845 to ·915. Oleum pulegii, oleum rutæ and oleum sabinæ were briefly mentioned, and the paper was brought to a conclusion with a description of ol. lavandulæ, dealing chiefly with the cultivation of the plant in this country.

A short discussion followed, in which the President, Messrs. Burnett, Cracknell, Palmer and Winfrey took part.

At a meeting of the above Association, held on December 6, 1883, Mr. Parkinson (President) in the chair, a paper on "Digestion" was read by R. Wharry, M.D.

Dr. Wharry opened his paper with a short note of the average amount of food and the nature of it required per diem by a healthy man having a fair amount of out-door exercise. The classification of foods was then given, being as follows:—Organic and inorganic, the organic being sub-divided into nitrogenous and non-nitrogenous, while the non-nitrogenous were again sub-divided into hydrocarbons or fats and carbohydrates or amyloids, including the starches and sugar. It was stated to be impossible to sustain life very long upon a purely nitrogenous or a purely non-nitrogenous diet. The chemical changes which the food undergoes by the action of the saliva upon it were described, as also the action of the gastric juice upon the masticated food, rendering it ready for absorption; the action of the bile was alluded to, its chief use being to emulsify the fatty constituents of the food, thus preparing them for absorption; the pancreatic juice also acts at the same time as the bile. The *succus entericus* was next mentioned; it is a fluid secreted by the numerous tubular glands that open everywhere on to the surface of the intestine, but as it is difficult to isolate it information about it is only very limited. Dr. Wharry then fully described the absorption of the food thus prepared, mentioning the absorption through the walls of the minute blood-vessels into the blood. The action of purgatives on the organs which take part in the process of digestion was briefly alluded to.

A long discussion followed, in which the President, Messrs. Braithwaite, Briggs, Burnett, Cooper, Cracknell, Millhouse, Warrick and Winfrey took part.

A hearty vote of thanks to Dr. Wharry for his interesting and valuable paper, proposed by Mr. Winfrey and seconded by Mr. Braithwaite, was carried unanimously, and the meeting then adjourned.

SOCIETY OF ARTS.

The Scientific Basis of Cookery.

In the second Cantor lecture upon "The Scientific Basis of Cookery" last Monday, Mr. Mattieu Williams referred in detail to the process of frying. He stated that in this country the operation is understood very little, and he believed it was a common opinion, in regard to fish especially, that the oil or grease was merely used to prevent the substance being cooked from adhering to the pan. He said people were under the impression that if more oil than was sufficient for this purpose were used it would not only be wasteful, but would make the fish oily; but in fact fish should be entirely immersed in fat, for so long as the temperature was maintained above 212° F., the steam from the water contained in the fish would effectually prevent any oil entering it. The loud frizzing noise heard when the fish was first put into the heated oil was due to numberless explosions of superheated water vapour The method commonly followed of laying the fish upon a greasy iron plate would, on the contrary, give a greater opportunity for the fat to saturate the fish, as when one side was browned, the fish was turned over and became cooled below 212° F.; and as soon as the temperature became so low, the steam which had previously kept the fat out, now condensed and the fat was sucked in. As the fat when used in a large quantity could be used more than once, liberality in this respect would be more economical than the ordinary mode of only greasing the pan every time it is used. The lecturer then enumerated the constituents of animal food, referring first to albumen, which he said was first used in the body as a lubricating agent, and after doing service in that way was utilized as a nutritive fluid. In referring to gelatin, as composing the cell walls, membranes and tissues of the body, he pointed out that in its natural condition it is insoluble in cold water, but that after continued immersion in hot water it became soluble and was obtained in the condition familiar in calves'-foot jelly and similar preparations. He added that an attempt had been made to distinguish between the raw and cooked substance, by naming it in the one condition "gelatin" and in the other "gelatine." He also referred to other bodies resembling gelatine, such as chondrin, occurring in the tendons, and fibroin in spider's web, silk, etc. In comparing albumen and gelatine, the lecturer pointed out that, when heated, albumen is converted from a viscous liquid into a solid, but that gelatine, on the contrary, if the temperature be kept below 212° F., changes from a solid into a liquid state. He further pointed out that although the Bone Soup Commission of the French Academy came to the conclusion that gelatine is not a nutritious substance, further experiments had qualified this opinion and shown that it was more correct to say that it was incapable of supporting life when used alone. The lecturer, in noticing tinned meat, mentioned that a great difficulty was experienced in effecting the necessary complete exhaustion of air from the tins, and also remarked that the process followed caused the albumen of the meat to become hardened and the gelatine to be dissolved, the solution of the gelatine also causing the fibres of the meat to fall apart, giving rise to a delusive appearance of tenderness. After explaining the formation and use of caramel, Mr. Williams stated that he would postpone the important subject of cheese to the third lecture.

Parliamentary and Law Proceedings.

The Recent Poisoning Case at Partick.

An action for £1000, which had been raised in the Glasgow Sheriff Court in connection with the recent poisoning case at Partick, has just been settled.

The pursuer, William M'Kay, was the father of the young man who lost his life, while the defender was Mr. Rait, chemist, Partick. M'Kay stated that his son was an apprentice fitter, earning about £3 per week. On June 4 last, having contracted a bad cold, he called upon Dr. Young, who prescribed certain medicine, consisting of, *inter alia*, tincture of actea racemosa, and for which the doctor wrote out a prescription. The ingredients of that prescription were quite harmless, and the order was taken by pursuer's daughter to defender's premises in Partick. A mixture representing to be what was asked for was made up by a salesman in defender's shop and handed to the girl. The mixture, however, instead of being according to order, is alleged to have contained a quantity of tincture of aconite, a virulent poison, and pursuer's son, having partaken of the medicine in the belief that it was what had been prescribed by his medical adviser, died on June 6.

The defender explained that he was from home at the time, and that his shop was in charge of a manager of long experience as a chemist and druggist. One of the ingredients in the prescription presented to the salesman was tincture of actea racemosa, a liquid extracted from an American root seldom prescribed by medical men. Defender further stated that the tincture had not been prepared by himself, but was obtained from a wholesale druggist in the same state that he dispensed it, and it was not ascertained till after the medicine had been supplied to the girl that it contained a strong preparation of aconite. He further mentioned that when he became satisfied that the death of George M'Kay had been caused by poison, he expressed great regret at the loss pursuer had sustained, and offered, before the raising of the action, to pay the sum of £150 in full of all claims.

When the case was called before Sheriff Lees, on Wednesday, the 5th inst., for adjustment the parties presented a joint-minute, setting forth that the defender, having paid the pursuer the sum of £200 and expenses, the latter had accepted that sum in full of all claims.

His Lordship, in terms of this arrangement, issued an interlocutor dismissing the action without expenses.—*Glasgow Herald.*

Death of a Surgeon from Overdoses of Chloral Hydrate.

On December 10, Mr. Barstow, Coroner, held an inquest at Lindley, near Huddersfield, touching the death of William Hunter, M.D., aged 37 years, who died early on Saturday morning in the presence of his housekeeper, Isabel Roper.

The evidence showed that for six weeks Dr. Hunter, who come from Glasgow, had been drinking, and on Tuesday last week he took to his bed, and began taking chloral hydrate, which he always took when he had been drinking. It did not induce sleep, and about eleven o'clock on Friday night he took a strong dose of chlorodyne, and in about an hour and a half after the housekeeper (who had been in constant attendance on him since Tuesday) heard him him groan, tried to raise him, and saw him die almost immediately.

Mr. Erson, surgeon, who was called, showed that death had arisen from taking overdoses of chloral hydrate and chlorodyne to induce sleep.

The Jury found a verdict in accordance with the medical testimony.

Poisons: their Effects and Detection. By Alexander Winter Blyth, M.R.C.S., F.C.S. London: C. Griffin and Co. 1884. From the Publishers.

Reviews.

Les Produits de la Nature Japonaise et Chinoise. By A. J. C. Geerts. (Part II.)*

This work, written by a laborious and learned author, whose recent death is matter for sincere regret, forms part of a series, the present volume being devoted to a description of substances which are derived from the mineral kingdom. The whole was intended as a contribution to the pharmacology of Japan and China, showing how the various natural products enumerated are employed in the Eastern Hemisphere, in the arts, commerce, domestic economy and medicine.

As a book of reference respecting the special class of subjects on which it treats these pages will have a peculiar interest, since the author has elaborately gleaned his information from every possible source, and has invariably quoted the authorities on which statements are founded. While, then, the practical pharmacist will find little which he can turn to a directly useful purpose, the general reader and the pharmacologist will be rewarded by a perusal of these pages, for they will learn many curious historical details, and will see with what intelligence many manufacturing processes have been carried on in China and Japan. We are all disposed to grant a large share of manipulative skill to these nations: their methods of preparation are ingenious and often most effective. So long as the results of their industry belong to trade, we, with all our refinements, and improved apparatus might frequently be content to copy their example. But as regards the application of these products either to pharmacy or medicine, it would be strained humility not to acknowledge the superiority of the west. Of this no better proof could be afforded than the work just now under consideration. It contains little which might be termed of a popular nature, and its contents deal generally in carefully ascertained facts; and the genius of the two nations depicted seems strangely bounded by the mechanical. The same people who can make blue china to admiration have in their list of materia medica more than sixty varieties of earths, to most of which fantastic properties are assigned; many of them are nasty, and the rest of exceedingly doubtful value.

The author has permitted himself one stroke of humour when he remarks:—"The Chinese writer has had the happy idea of ending his enumeration of the earths by soap, as if he wished to wash out and efface so many dirty matters. We," the writer continues, "do the same, and have no need to state that all that has been written on 'Earth according to native books' rests on the sole responsibility of Asiatic authors."

It appears that some discretion must be used in accepting Chinese nomenclature, for when chemical terms are employed they are used with a degree of laxity not consistent with our more rigid rules. The salts of potash and soda are even frequently confused. Saltpetre is extensively prepared both in China and Japan, and is an article of considerable commercial importance. This salt has been known to the Chinese from time immemorial, and with it they manufactured explosive mixtures, petards and fireworks long before it was known to the Arabs and the western nations. But M. Geerts considers that it is a mistake to suppose that gunpowder was known in China previous to a knowledge of its use having been learnt from Europeans. Their ancient pyrotechnic mixtures were never used for firearms, which were completely unknown in the far east before the arrival of the "barbarians" from the west.

The mode of the preparation of saltpetre is minutely described, as is also that of the various salts of potassium, sodium, iron, cobalt, lead and other metals which are utilized either in the arts or for trade purposes. A wonderful amount of miscellaneous information has been grouped together by the industrious author with regard

* Yokohama: Levy and Salabelle. 1883. Pp. i.—viii., 297—662.

to native manufactures, proving that had modern science directed their ingenuity, China and Japan would hold no mean place in the history of technology.

Not the least curious portion of the book is where it treats of the medical application of familiar substances. Thus wood ash, which is scarcely employed in European pharmacy save for the preparation of a strong liquor potassæ, appears in China to be a favourite remedy for various complaints. It is esteemed also for its supposed power of resuscitating from apparent death by drowning or long exposure to the cold.

The mode of application borders on the grotesque, but the author states that one can easily be convinced of the efficacy of the treatment by practising on an insect rescued from the water. Placing it in a bed of moderately warmed ashes it will soon come to life. It will occur to most that gentle warmth would attain the same happy end without the aid of the much-praised remedy.

The term kaolin will naturally be sought for in an essay on Chinese materia medica. The subject is treated at some length, comparative analyses being given of substances known under that name in China, Japan and France. The term, which has been given in Europe to a pure clay not containing more than from 43 per cent. to 58 per cent. of silica, is derived from the mountain, Kau-ling, situated to the east of the porcelain factories in the province of Kiangsi. But this true kaolin is firm and hard and not plastic. Whence, says the author, we are in error in giving the name to the plastic material of porcelain, instead, as in the east, of assigning it to the hard, fusible, non-plastic substances which enter into its composition (p. 372). The former is called kaolinite. The disquisition on porcelain manufacture is foreign to our purpose. Pumice stone, which is recommended for a host of maladies, is still believed by the Chinese to be a product of the sea-foam and not of volcanic origin. Precious stones, to some of which marvellous virtues are attributed, have a chapter to themselves. One story will suffice. A man learnt the use of jade and duly reduced the precious stone to powder and took his daily dose. At first he was in excellent health but soon was attacked by a mortal disease. Summoning his wife and children he thus spoke: "He who would be cured by jade must be chaste and pure and drink no wine. He must live secluded in the mountains or the forest and flee society. But I have drunk much wine and led a vicious life, and if I am about to die, it is not the medicine's fault, but in consequence of my own sins. Yet listen, wife; leave my body exposed some days before interment, and something wonderful will be beheld." The wife obeyed her husband's wish, and was astonished to perceive that even four days after death, though it was in the heat of summer, neither the corpse changed colour nor did the mouth smell.

It would be unfair to the author and his book to imagine that such episodes formed a leading portion of the treatise. On the contrary the work is filled with minute descriptions of manufacturing processes adopted by the Chinese and Japanese. Rude, outline sketches, copied from native artists, illustrate the volume.

Had the author lived to complete the series no small addition would have been made to our knowledge of technical industry in the two countries so carefully described. As it is, the work is sufficiently advanced to prove the unwearied diligence of the writer whilst engaged on a research which obviously enlisted his entire personal sympathy.

NOTES ON THE DETECTION OF THE ACIDS, INORGANIC AND ORGANIC, USUALLY MET WITH IN ANALYSIS. By J. W. JAMES, Ph.D.*

The publication of this book is totally uncalled for. Had the author been better versed in the contents of existing chemical manuals, the statement in the preface that "the acids have received but little attention as far as their recognition when mixed is concerned" would not have been made, and had he been acquainted with the general principles of science-teaching the book never published. It is indeed a sorry affair. In fifteen pages of the largest type the principal reactions of the inorganic and organic acids of common occurrence are stated, with a view to their detection when occurring together. So condensed is this tabulation that we doubt whether a student would be able, by its aid alone, to detect the constituents of the simplest mixture or, indeed, even to keep a clear head while reading the description of some of the methods. This alone is a sufficient condemnation, and we have neither the time nor inclination to point out other instances which demonstrate the failure of the book to carry out the object stated in the preface, the "simplifying and rendering more reliable the investigation of a mixture of acids."

The progress of the chemical student of average intelligence, who has studied the reactions of known acids in a systematic way, will rather be hampered than otherwise by the use of such a "chart" as this. Even those who believe that students should be trained to analyse like machines, will, at least, stipulate that the methods which they are taught shall be efficient.

RELIGIO MEDICI. By Sir THOMAS BROWNE, Physician. Being a Fac simile of the First Edition, published in 1642. With an Introduction by W. A. GREENHILL, M.D. Oxon.*

The increasing acceptance that has attended in recent years the production of new editions of the English classics is a welcome sign of the spread of a purer literary taste in the country. Most of these editions have been simply reprints in modern form; but are marvels of correctness and cheapness. Mr. Elliot Stock has, however, been working in another direction and has become celebrated for his issue of *fac simile* reproductions of several famous old works which adorn our English literature. Of these the '*Religio Medici*' of Sir Thomas Browne is the latest, and the humble bibliophile who does not possess an original edition may now indulge in the learned garrulity and Latino-English of this kindly, wise and humorous writer, with the accompaniments of "all the defects of type, false punctuation and quaint spelling" of two hundred and forty years ago. The edition chosen for reproduction is the first, which is said to have been printed without the consent of the author, and was the pretext for the issue of a second edition which he revised and corrected. A list of these corrections is given in the introduction.

THE EXTRA PHARMACOPŒIA OF UNOFFICIAL DRUGS AND CHEMICAL AND PHARMACEUTICAL PREPARATIONS. By WILLIAM MARTINDALE, F.C.S., and W. WYNN WESTCOTT, M.B. Lond. Second Edition.†

We have so recently expressed our opinion as to the value of this little book that we need do little more on this occasion than announce the issue of a second edition and congratulate the authors on the fact that it has been called for after so short an interval. We notice, however, that several additional drugs and chemical preparations have been inserted and some slight errors that had escaped observation in the first edition have been corrected. A Therapeutic Index has also been added, which will make the book even more useful than it was before to the medical practitioner.

Tincture of Nux-vomica.

Sir,—I have read with much interest the correspondence relating to this tincture, and believe Mr. Hick is correct in saying that few retail chemists make it according to the B.P. formula; a great number do not make it at all, for there is an evil creeping insidiously into the retail trade, viz., delegating to wholesale traders (some of whom have little or no knowledge of the Pharmacopœia) the duty of making its preparations and distributing them through the trade, the profession, and even outside the trade, at a minimum of a profit, thus bringing dishonour upon a number of our B.P. preparations, such as its pills and potions. This I know encroaches upon a subject which is at present depressing our trade here, there, and everywhere. I will not, therefore, enlarge, but remark that I have just made (as I have for the last twelve years) my usual pint of tincture of nux-vomica as well as ignatia amara, certainly not with the same facility as Mr. Hick says he can weigh 120 grains of extract and dissolve in s.v.r., for I do not mind trouble, if by so doing I can make a better and more reliable preparation.

My *modus operandi* is as follows:—I weigh 2 ounces and 2 drachms of the seeds and place them in a mortar over night, just moistened with warm distilled water. I am not blessed with a laboratory and its conveniences, therefore, the next morning I transfer them on to a water-bath, adding, as required, more water; in about an hour I can cut the seeds into very small pieces with ease. After rapidly drying they can be easily powdered. Of course the 2 drachms extra is to ensure the right quantity, as there may be loss in powdering.

Sandford.

An Examination of some Samples of Pitch and Asphalt.

Sir,—Mr. E. Davies, F.I.C., F.C.S., in his paper read before the Conference and published in the *Pharmaceutical Journal* of November 17, remarks that the determination of the amount of matter soluble in petroleum spirit, sp. gr. ·700, does not admit of very great precision.

In my varied experience in analysis of asphalt, especially that of Val de Travers, I have always used carbon bisulphide (purified) for the determination of the pitch or bitumen, using the same process as Mr. Davies, only without the application of heat.

The CS_2 dissolves the bitumen when pure completely, leaving the limestone (in the case of the Val de Travers) in a perfectly white condition. Should the carbon bisulphide not dissolve all the organic matter, but leave a dark residue, it shows that the asphalt contains organic matter other than bitumen, such matter being useless for the purposes to which asphalt is applied. It is estimated by igniting the residue after extraction with CS_2, re-carbonating with ammonium carbonate the caustic bases formed, and weighing.

I find that when CS_2 leaves a perfectly white residue the bitumen can be estimated by igniting a weighed portion of the asphalt in a platinum crucible, recarbonating the bases as above with ammonium carbonate, again igniting at a low red heat and weighing, deducting, of course, from the result the moisture contained in the sample. My analysis by the CS_2 method I always check when possible by an ignition experiment, and the results always agree within a decimal point.

The following test, proposed by MM. Durand-Claye and Hervé Mangon, of the Ecole des Ponts et Chaussées, for distinguishing between gas-tar or artificial pitch, and bitumen or natural pitch, may be useful. Into a tube containing 1 gram of material, about 5 c.c. of rectified benzine are poured, and the mixture shaken repeatedly until the benzine becomes almost black; 5 or 6 drops of the liquor are filtered into another glass tube and diluted with about 5 c.c. of rectified benzine, and an equal volume of 85 per cent. alcohol is added. The contents of the tube are then agitated and allowed to settle. The liquid soon separates into two distinct layers; the upper is benzine strongly coloured by the dissolved matter, the lower layer is formed of alcohol. This alcohol is coloured golden yellow by gas-tar, and is hardly coloured at all by bitumen, or at any rate only shows a scarcely perceptible straw-coloured tint. The yellow colouring is plainly visible when a mixture of the two substances is treated, even when gas-tar only enters for one-tenth part.

Hornsey. H. P. Cooper, F.C.S.

"*Quercus.*"—Most likely the "dog" Latin has been misread.

"*Associate.*"—The formula of the B.P. yields a very satisfactory and soluble collodion, if the instructions are carefully followed.

A. J. Swadling.—The B.P. contemplates suppositories of about 15 grains each. The ingredients in the prescription sent are 60 grains. Each will require about 5 grains of tragacanth and 5 grains of cacao butter.

"*Kino.*"—(1) No. (2) The changes alluded to do not occur with iodine and ether in proper condition.

C. Pridham.—There is no discoloration when the ingredients used are B.P.

G. J. Gostling.—The ext. cinchonæ liq. of different makers differ very much in their behaviour when dispensed in mixtures. The mixture in question would be of a brown colour, slightly opaque, with a flocculent precipitate.

Pharmacist, U.S.A.—The ext. cinchonæ rub. would be the fluid extract. The ingredients should be rubbed together without the aid of heat.

T. A. W.—Glycerine of tragacanth in a gelatinous condition.

C. Potter.—The supply of small quantities of pure spirit for any purpose by an unlicensed person is illegal.

"*Apprentice.*"—(1) *Eriophorum vaginatum.* (2) *Geum rivale.* (3) *Knautia arvensis.* (4) *Pyrola minor.* (5) *Stellaria Holostea.* (6) *Lychnis Githago.*

"*Tinct. Rhei Co.*"—(1) The name is rather of the nature of a trade mark than indicative of a particular perfume. (2) See a number of recipes in vol. x., pp. 1009, 1031, 1051.

W. W. Morris.—The New Zealand Pharmacy Act, sect. 19, provides that any person who "holds a certificate or diploma of competency as a pharmaceutical chemist or chemist and druggist from the Pharmaceutical Society of Great Britain" shall be entitled to registration without further examination.

E. Dodds.—The 16th section of the Pharmacy Act, 1868, provides that nothing contained in the previous sections shall extend to or interfere with the business of any legally qualified apothecary.

Annikcam.—If you are in a position to prove that any of the preparations sold in the manner described contain a scheduled poison, you are recommended to communicate with the Registrar.

"*Dispenser.*"—(1) All such matters are subjects of private arrangement, and are influenced by too many conditions to allow of a definite answer being given. (2) Not necessarily, unless you wish to commence business on your own account, in which case you will have to pass the legal examinations.

Fraxinus.—According to the U.S.P., "petroleum ether" is the portion of distillate from American petroleum which has a specific gravity from 0·670 to 0·675, and boils at 50° to 60° C.

F. C. Allen.—The 'Extra Pharmacopœia' gives the following formula for "Vapor Iodi Ætherealis," which will possibly answer your purpose:—Iodine, 3 grains; ether, 2 drachms; carbolic acid, 2 drachms; creasote, 1 drachm; rectified spirit, 3 drachms. Ten minims to be dropped on the respirator before inhalation.

ANALYSIS OF SOME SAMPLES OF NATURAL AND RENEWED SUCCIRUBRA BARK FROM THE SAME QUILLS.

BY JOHN HODGKIN, F.I.C., F.C.S.

A parcel in a recent consignment of Ceylon succirubra consisted of quills of natural and renewed bark in juxtaposition; these quills were about a foot long, the upper half being renewed bark (No. 3), whilst the lower portion was natural (No. 2). As in the same consignment there were parcels of bark ntirely natural (No. 1), and also bark entirely enewed (No. 4), an opportunity offered itself for testing whether the renewed and natural barks in direct contact with one another afforded intermediate results to those obtained from the unmixed barks.

The quantity experimented upon in each case was identical, and the percentage of moisture contained in the various barks was noted, in order that the analyses might be brought to one level for greater ease in comparison. The results, therefore, have all been calculated to Moens' standard hydration, viz., 13·5 per cent. The natural bark was carefully separated from the renewed bark by means of a pair of scissors. This was easily done, since the quills were thin and the bark somewhat flexible, owing to the high percentage of moisture contained therein.

No.	Description of bark.	Percentage of moisture in the bark.	Quinine sulphate.	Cinchonidine sulphate.	Quinine.	Cinchonidine.	Cinchonine.	Quinidine.	Amorphous alkaloid.	Total alkaloid.
1	Natural Quills.	13·33	1·352	0·948	1·014	0·711	0·661	Trace	1·222	3·608
2	Natural portion from Natural/Renewed Quills .	14·61	0·622	0·941	0·467	0·706	0·849	,,	0·888	2·910
3	Renewed portion from the same Quills .	15·96	1·474	2·076	1·050	1·557	0·817	0·051	0·810	4·285
4	Renewed Quills	13·84	2·311	2·379	1·744	1·784	0·717	Trace	0·871	6·116

It is worthy of note that the hydration differed considerably in the natural and renewed portion in the same quill. The renewed portions contained more water, probably owing to the soft spongy renewal, which had evidently been accomplished by shaving and not stripping.

The results are rather surprising, but it must be carefully borne in mind that trees grown apparently under precisely similar conditions, from the same seed, and, in addition, presenting the same physical appearance, will, on analysis, turn out widely different as regards their chemical composition.

If it should be the case that the natural bark (No. 2) has suffered in the renewal, it will probably be found to be owing to some temporary injury to the tree caused by the shaving process, as in McIvor's experiments no such deterioration was found. As regards No. 3, of course, the reason for such a small increase in alkaloid is due to the fact that this bark consisted of those portions of the quill where the shaving ended, and, consequently, only a very thin layer of original bark had been removed.

Where a thicker layer, as in No. 4, had been removed, the increase in alkaloids was well marked. No. 3 was the only one that gave an appreciable quantity of quinidine, the others only giving a faint trace.

FURTHER NOTES ON VEGETABLE TALLOW FROM SINGAPORE.

BY E. M. HOLMES, F.L.S.,

Curator of the Museum of the Pharmaceutical Society.

I have perused Mr. W. T. Thiselton Dyer's comments (*Pharm. Journ.*, Dec. 15, p. 462) on my previous paper on this subject (*Pharm. Journ.*, Nov. 26, p. 401) with much interest, and have to thank him for drawing my attention to the existence of a fat obtained from a Sapotaceous plant at Bandjermassing, and to the admirable treatise on Minjak Tangkwang by Dr. W. H. de Vriese.

I cannot, however, agree with Mr. Dyer that the Sapotaceous plant he mentions as coming from Bandjermassing is the source either of the fat or seeds sent to me by Mr. Jamie from Singapore, and mentioned on p. 371. These seeds and fat came from Pontianak and Sarawak, not from Bandjermassing.

Mr. Dyer has expressed the hope that his doubts attending the origin of this interesting substance will be cleared up by myself and Professor Van Eeden. I have much pleasure, therefore, in giving such information as I possess, and will take up, *seriatim*, the various points raised by Mr. Dyer (p. 462).

I. With regard to the Sapotaceous plant sent to the Kew Herbarium by Madame de Vries de Vries, Dr. W. H. de Vriese expressly states, in the tract alluded to by Mr. Dyer, that several different fats pass under the name of "Minjak Tankawang," and enumerates some of them, as shown in the following quotation, from p. 9:—

"The fat, Minjak Tangkawang, is also known at Singapore under the name of Vegetable Tallow. But under this name different kinds of fats occur in Borneo, Java and Japan. Thus there is—

"1st. The vegetable tallow of the fruit of an *Isonandra* (Gutta Percha tree) prepared in the eastern part of Borneo.

"2nd. The fat of *Cylicodaphne sebifera* (*Litsæa sebifera*), a kind of Lauraceous plant. This is obtained from one of the largest and most lofty trees of the westerly part of Java, and is brought over to the middle and east of Java. Near the Court-house at Salatiga a large tree stands, the seeds of which furnish 500–600 candles annually, sufficient for the lighting of the house. This is the *Minjak Tangkallah.*

"3rd. The fat of *Stillingia sebifera*, the tallow or wax tree of Japan.

"4th. The fat of the berries of *Rhus succedanea* of Japan.

"5th. The fat of different *Sapotaceæ*, from species of *Cacosmanthus* in Java.

"All these and many more are classed under the name of vegetable tallow, affording another instance of the enormous confusion in names and articles in commerce."

To the above list he adds six species of *Hopea* which he calls tallow trees, and which I shall allude to hereafter.

The Sapotaceous plant mentioned by Mr. Dyer is, therefore, judging from the above remarks by Dr. W. H. de Vriese, only one out of several used for the purpose. Whether it be identical with the No. 1 (*Isonandra*) of Dr. de Vriese's list or no, I have no evidence to show; but the plant in the Kew Herbarium received from Madame de Vries de Vries, and alluded to by Mr. Dyer, also comes from the eastern side of the island, Bandjermassing being in the south-east of Borneo. This plant, I learn from Professor Van Eeden, is now determined by M. Pierre to belong to a new genus of *Sapotaceæ*, thus confirming Professor Oliver's opinion. Dr. Pierre has named it *Diploknema sebifera*, and the description and figures will, Professor Van Eeden believes, shortly be published in the *Archives Néerlandaises des Sciences Exactes et Naturelles*, issued by the Haarlem Society of Sciences, a copy of which Professor Van Eeden has kindly promised to forward to me as soon as published.

It is evident, therefore, that Mr. Dyer's Sapotaceous plant is only one of the numerous sources of Minjak Tankawang, but there is no proof that it yields the particular kind described by me.

II. The next point raised by Mr. Dyer is the following:—He remarks (p. 462) "It is *à priori* unlikely, however, that any species of *Dipterocarpeæ* would yield a vegetable tallow from the seeds, because the members of the family are characterized by the presence of oleo-resins in the tissues and not of fatty bodies." This is given as a reason why the vegetable tallow I have mentioned cannot be derived from a Dipterocarpous plant.

In confirmation of my opinion that the seeds sent me by Mr. Jamie *are* those of a Dipterocarpous plant, and that fixed oil *is* obtained from Dipterocarpous seeds, I may say,—

a. That previous to publishing any account of the fat, I had shown the seeds sent with it to Professor Oliver, who at once referred them to the *Dipterocarpeæ* and now agrees with me that they probably belong to the genus *Shorea*, as limited by Bentham. This genus is said by Bentham to be scarcely distinct from *Hopea*, the former having as a chief distinguishing character three or more of the lobes of the calyx enlarged unequally when in fruit, and the latter only two enlarged.

b. That in the No 1 Museum, at Kew, there are specimens of the fats of the seeds of two Dipterocarpous plants, viz., the fat of *Vateria indica*, well known to yield resin in the bark, and the vegetable tallow from Singapore. In another part of the Museum, among unnamed products, there are some of the larger Dipterocarpous seeds, identical with those sent me by Mr. Jamie (probably *Hopea macrophylla*, de Vriese). There is also a specimen of the fruit of *Lophira alata* (*Dipterocarpeæ*) labelled, "Seeds from which an oil called Meni is obtained."

c. In Dr. W. H. de Vriese's tract, six species of tallow trees which are said by him to yield the vegetable tallow, Minjak Tankawang, are described. These are *Hopea macrophylla*, *H. splendida*, *H. Balangeran*, *H. aspera*, *H. lanceolata* and *H. Seminis*.

In the copy of this tract in the magnificent botanical library at Kew, some of these species have been identified doubtfully, in what I am informed is Mr. Dyer's handwriting, two of them as a species of *Shorea* and one as a species of *Vateria*. The only explanation that seems possible is, either that Mr. Dyer had not read the text, which is in Dutch, and had referred only to the Latin description of the species, or that he doubted the statements of Dr. W. H. de Vriese and of other authorities whom Dr. de Vriese quotes, that the vegetable tallow was obtained from any Dipterocarpous plants.

d. Mr. F. W. Burbidge, the author of a most interesting book on Borneo, has kindly furnished me with the following information concerning the preparation of oil or fat from Dipterocarpous seeds:—

"The only place I saw the manufacture of oil from Dipterocarpous seeds was in a little village situated on the Lawas River, between Labuan Island and Brunei. The seeds are placed in a leather bag or folded mat, which is enclosed in a tough palm sheath folded into a V-shape, so as to form a spout for the oil to drain into the receptacle placed to receive it. This sheath is placed obliquely in the press, so that an 'oil shed' is formed, towards the side on which the receiver or cooking pot is placed. The oil press or *Teudasun* consists of a stout plank placed on two upright supports, fixed also into another stout plank at the base. In an opening in the horizontal planks are two vertical boards placed obliquely, between which the bag of seeds is placed, the pressure being applied by wedges forcibly driven in behind the vertical boards.

"The Dipterocarpous seeds (at least three species are used) are collected and thrown into heaps, and are then allowed to 'massuck' as the Malays say, or 'blet,' as we should say in English, before they are pressed. The pure oil is used in cooking and the refuse is used in the making of candles or rather rude torches. The process here described is used by the Kadyans, a clean and healthy Mahommedan tribe of Borneans, who live on the Lawas and Merapok Rivers, and to whom animal fat is an abomination."

Mr. Burbidge gives a sketch of the fruits, which are evidently Dipterocarpous, and apparently have more than three enlarged calyx lobes; they correspond well as regards size with the smaller Dipterocarpous seeds I have received from Mr. Jamie.

e. Professor Bernardin, of Melle-lez-Gand, in reply to my inquiry if he could give any information as to the botanical source of Minjak Tangkawang, says, "I think the tallow comes from *Hopea macrophylla*, *vide* Wiesner, *Rohstoffe*, p. 197." He sends me a portion of a seed said to yield it, which corresponds exactly with the larger variety sent me by Mr. Jamie.

I hope the above statements from competent authorities may be sufficient to show that I am justified in saying that the particular kind of Singapore vegetable tallow sent me by Mr. Jamie is derived from Dipterocarpous seeds, which may be referred to the genus *Hopea* by most writers on the subject, although by some botanists they may be considered to belong to other genera of *Dipterocarpeæ*, and that it is *not à priori* unlikely that any species of *Dipterocarpeæ* would yield a vegetable tallow from the seeds.

I may add here, that I can see nothing improbable in the occurrence of fixed oil in the seed of a plant which yields a resin or oleo-resin in the bark, etc. The *Dipterocarpeæ* is not the only family in which this occurs. *Canarium commune* (*Burseraceæ*) yields a semi-solid oil from the seed and an oleo-resin from the bark. *Garcinia pictoria* (*Guttiferæ*) also yields a fat (solid in this country) from the seed and a gum-resin from the bark. The chemistry of plant life is so little known at present that we are scarcely in a position to say under what circumstances or by what means resins, fat and caoutchouc are formed in plants, or that all of them might not be formed in the same plant, either by vegetable ferments or by strictly chemical processes.

III. The last point raised by Mr. Dyer is the identity of the vegetable tallow presented to the Museum by Mr. Jamie with two or three specimens in the Kew Museum.

I have seen the specimens in the Kew Museum, and, through the kindness of the Curator, Mr. J. R. Jackson, have been permitted to examine them.

I find that one of the specimens in the form of a cylinder is identical with Mr. Jamie's Dipterocarpous tallow, although labelled "*Bassia* sp."? Another specimen labelled, as Mr. Dyer remarks, "*Bassia* sp.", is of quite a different character. It has a rancid odour, is in crumbling irregular pieces, and resembles in appearance and consistence the fats of *Bassia* generally, and it is quite possible that it may be derived from the Bornean Sapotaceous plant recently named by Dr. Pierre. The third specimen labelled "Concrete oil, from a species of *Bassia*; *Sakarran*; Sir James Brooke," is totally different from the other two. It is enclosed in a bamboo joint, and consists of an almost pulverulent micaceous mass, with a strong and fragrant odour, between that of sassafras and nutmeg. The crystalline scales of which it consists closely resemble in appearance those of myristic acid. The fat appears to have soaked through the bamboo and has formed an efflorescence of micaceous crystals outside it. I should judge from the above characters that the fat is obtained from the seeds of some Lauraceous plant, possibly from the *Cylicodaphne sebifera* mentioned by Dr. W. H. de Vriese.

To recapitulate: The vegetable tallow and seeds presented to the Museum of the Pharmaceutical Society by Mr. R. Jamie are certainly of Dipterocarpous origin, and are, in all probability, the produce of trees which have been placed by Dr. W. H. de Vriese in the genus *Hopea*, but which may possibly belong to allied genera, according to the views held by different botanists, but they are undoubtedly *not* of Sapotaceous origin.

The Sapotaceous plant sent to Kew by Madame de Vries de Vries, named by Dr. Pierre, is most probably the source of one of the kinds of vegetable tallow of Borneo and possibly of the second specimen in the Kew Museum, but not of that presented by Mr. Jamie to the Museum of the Pharmaceutical Society. Lastly, the aromatic tallow, No. 3 of the Kew Museum, from Borneo, is most likely the produce of *Cylicodaphne sebifera*, although, in consequence of the absence of an authentic specimen for comparison, it is difficult to satisfactorily determine its identity. This last-named product seems, however, worthy of attention as an aromatic fat and of chemical examination with respect to the fatty acids and volatile oil it contains.

TINCTURE DEPOSITS.*

BY R. A. CRIPPS.

[Contribution from the Research Fund of the School of Pharmacy Students' Association.]

Every pharmacist must have noticed the fact that most of his tinctures, after having been filtered, deposit sooner or later a more or less bulky sediment. The importance of knowing the nature of these deposits at once suggests itself to everyone. Is it that they contain some of the active principles of the drugs, or are they only gummy or albuminous matter, of no value in medicine? It is with the view of throwing some light upon this question that I have undertaken their investigation, feeling that my work, however imperfect, will be one step towards a deeper knowledge of the chemistry of some of the pharmacist's practical difficulties.

1. *Tinctura Calumbæ.*—The deposit in this tincture usually occurs in flaky pieces of a light olive-brown colour, mixed with a gummy-looking substance of the same nature. Under the microscope the sample under examination formed a very interesting object, as it consisted principally of finely-formed starch granules, similar to a mixture of arrowroot and wheat starches, showing very distinctly the hilum and concentric rings, and with the polariscope a fine black cross; with the starch was mixed a quantity of matter of no definite structure, and a few very fine tubular vessels of a bright yellow colour.

The starch was confirmed by adding iodine to the cooled decoction of the deposit, when the usual blue colour was developed.

After washing well with proof spirit (until the washings passed nearly colourless) the deposit was boiled with water, and afterwards with very dilute sulphuric acid; it gave a brownish-yellow solution, which on dilution with spirit, boiling and addition of dilute solution of iodine in iodide of potassium, gave no green spangles indicative of berberine, nor did it possess any markedly bitter taste, showing the absence of more than traces of colombin or colombic acid.

The deposit in tincture of calumba may therefore be said to contain none of the active principles of the drug, and, except for the inconvenience of filtering, is of no consequence.

Tinctura Cardamomi Composita.—This deposit occurs principally in minute crystals of a dirty white colour, with a small proportion of a flocculent substance. The crystalline form is well shown by a low power of the microscope, which reveals several different forms, a few octahedra, while others are hexagonal prisms with pyramidal apex and base, besides others more difficult to make out.

The deposit was first washed with proof spirit until the washings passed colourless or nearly so, then boiled with water and filtered. The filtrate was examined for metals, very carefully for potassium, and also for tartaric acid, but gave no evidence of the presence of either, proving that the deposit is not acid tartrate of potassium, as I think is the usual opinion.

The precipitate was then boiled with a strong solution of sodium carbonate for about three hours and filtered. The insoluble portion was examined for metals, *calcium* was alone found.

Looking at the constituents of the tincture I find that the deposit must consist of one or more of the following:—Tartrate or malate of calcium or oxalate of calcium.

The alkaline filtrate was therefore divided into four portions. To the first was added excess of solution of acetate of lead, the precipitate filtered off and dried upon a water-bath, ammonia added, again dried, then a few more drops of ammonia, and lastly digested with alcohol, which would dissolve any malate of ammonium if present; on evaporation of the alcoholic solution no residue was obtained, proving absence of malate of calcium.

To the second portion excess of acetic acid was

* Read at a meeting of the School of Pharmacy Students' Association, Nov. 29.

added, then solution of calcium chloride; no precipitate was formed, showing absence of oxalate of calcium.

To the third portion nitric acid was added to exact neutrality, a slight excess of nitrate of silver, and lastly ammonia in slight excess; on boiling for a short time a fine mirror of silver was obtained on the sides of the tube, giving strong suspicion of tartaric acid.

To the fourth portion were added excess of acetic acid, a little potassic hydrate, then more acetic acid (to ensure acidity), and lastly a small quantity of alcohol. On setting aside for a short time a white crystalline precipitate formed, which on the addition of strong sulphuric acid and gently warming gave off the odour of burnt sugar, indicating the presence of *tartaric acid.*

A small portion of the original aqueous solution was boiled with Fehling's solution, but gave scarcely any evidence of sugar, probably not more than due to adherent tincture. The deposit in tr. card. co. is therefore almost entirely tartrate of calcium.

Tinctura Chloroformi Composita, B.P.—As might be expected, this deposit is the same as that occurring in tinct. cardam. comp.

Tinctura Cinchonæ Composita, B.P.—This deposit was of a dark reddish brown colour, and in a state of very fine division, not at all aggregated into lumps or scales. 1·769 gram was treated as described further on under tinct. cinchonæ flav., and yielded ·0542 of a gram or 3·064 per cent. of total alkaloids. The acid solution of alkaloids was scarcely fluorescent, and gave only a faint green coloration with bromine and ammonic hydrate, indicating only traces of quinia or quinidia. A saturated solution of the sulphate, when shaken with half its volume of ether and excess of ammonia, afforded abundant evidence of the presence of cinchonia.

The colouring matter of cochineal was also present, as shown by the colour imparted to dilute HCl on boiling with the deposit, and by the addition of sulphate of zinc and ammonic hydrate in excess, when a fine violet tint was developed; ammonic hydrate alone giving a deep claret coloration.

The presence of cochineal entirely masked any reactions for cinchona-red which may have occurred.

Ferric chloride gave a faint reaction for cinchotannic acid.

The deposit was found to contain 3·064 per cent. of alkaloids, chiefly cinchonia, probably existing as cinchotannates; and a little colouring matter from the cochineal.

Tinctura Cinchonæ Flavæ, B.P.—Three samples of this deposit were examined, they varied much in appearance and nature.

1*st Sample.*—This was of a brown colour. Being in small quantity only it was simply tested for the presence of quinia and other alkaloids. It was well washed with proof spirit, to free it from adherent tincture, dried and mixed with milk of lime, thoroughly dried over a water-bath and extracted with chloroform. The chloroformic solution was shaken with dilute sulphuric acid (to dissolve out alkaloids as sulphates) and washed with water till free from bitterness. The acid solution of alkaloids thus obtained was shaken with chloroform and ammonia in slight excess, and the chloroformic solution separated and evaporated to dryness.

The residue which consisted of the pure alkaloids was now tested for quinia. 1st. By dissolving a little in dilute H_2SO_4, adding bromine water and then ammonic hydrate. A fine green coloration, due to thalleioquin appeared. 2nd. The remaining alkaloid was dissolved in a small quantity of hot dilute H_2SO_4, exactly neutralized with ammonic hydrate, still being kept hot, and set aside for a short time. An abundant supply of crystals appeared, showing the presence of quinia.

2*nd Sample.*—This sample was much lighter in colour than the other two, and far larger in proportion to the amount of tincture from which it separated. It was first examined quantitatively for alkaloids and for quinia. 7·237 grams were treated as above, the extraction with chloroform being performed in a "Dunstan and Short's apparatus for continual extraction," which I find by far the best for the purpose. After evaporation of the chloroformic solution the residue was dissolved in dilute H_2SO_4, heated upon a water-bath, exactly neutralized by AmHO and set aside to crystallize, filtered, well drained, and again dissolved in boiling water, set aside, the crystals collected, drained, dried at 100° C. and weighed. 0·156 of a gram was obtained, to which was added 0·0876 of a gram, being the amount of quinia sulphate retained by the mother liquors, equivalent to 2·94 per cent. of quinia, or 3·204 per cent. of crystalline sulphate of quinine. The mother liquors were now precipitated by ammonia and the alkaloids taken up by chloroform, which solution, on evaporation, yielded ·3182 of a gram of alkaloids, from which was deducted ·0697 of a gram (the quinia present) leaving ·2485 of a gram of alkaloids, not quinia, or 3·433 per cent.

The deposit, therefore, contains—

Total alkaloids	6·374 per cent.
Quinia	2·940 per cent.

Cinchotannic acid was proved by distilling the dry deposit, when an odour resembling carbolic acid was developed, and the distillate when tested with bromine water gave a white precipitate which rose to the surface of the liquid (tribromophenol); and by the slightly acid extract giving a faint greenish coloration with ferric chloride. Cinchona-red was proved as below.

3*rd Sample.*—This was of a very dark colour, having the appearance of cinchona-red. 1·35 gram was treated as before for alkaloids. The yield was only ·034 of a gram or 2·52 per cent. The solution was only faintly fluorescent. On attempting to crystallize out the quinia as sulphate, I succeeded in getting only a few very minute crystals, quite insufficient to weigh; and on testing for quinia by the thalleioquin test, I obtained only a faint reaction. A saturated solution of the sulphates, when mixed with half its volume of ether and excess of ammonic hydrate, afforded abundant evidence of the presence of cinchonidine.

Cinchotannic acid was proved as before.

Warmed with potassic hydrate or acetic acid it imparted a deep brown-red colour to the solution, due to cinchona-red.

From these three examples it will be seen that the deposit contains a very varying amount of alkaloids, and although the two latter were from tinctures prepared strictly according to the B.P. (the first I am not certain of), their nature both physically and chemically was very different.

Tinctura Ferri Acetatis.—This was washed with water; the first washings were found to contain free acetic acid. The deposit was then dried and weighed $= \cdot 1833$ of a gram, dissolved in diluted HCl, diluted, and the iron preciptated in the usual manner by AmHO. The precipitate, after washing and drying, weighed ·1279 of a gram, that is to say, the deposit represents 69·77 per cent. of oxide of iron, Fe_2O_3.

Ferric oxyacetate, $Fe_6O_7(C_2H_3O_2)_4$ represents 70·175 per cent. of ferric oxide.

Tinctura Gentianæ Composita.—This deposit was of a grey colour, and was mixed up with tow. It was first washed with proof spirit until the washings passed colourless or nearly so. Examined microscopically it was seen to consist mostly of very small starch granules, about the size of rice starch, but oval rather than angular. Some of the deposit was then gently boiled with water, cooled and solution of iodine added; a greenish-blue colour appeared, confirming the presence of starch. It was then washed with cold water, and the washings filtered and evaporated to dryness over a water-bath. The residue was nearly white and possessed no bitter taste, proving absence of gentiopicrin. Portions were then tested as follows:—1st. A small quantity was boiled with potash solution, a yellow colour was produced. 2nd. Another portion was tested with Fehling's solution, which it quickly reduced. 3rd. To a drop of solution of borax was added one drop of solution of phenol-phthalein, and then a few drops of the aqueous solution of residue. The pink colour was not discharged. The first two experiments show that the residue was sugar, and the last that the sugar of gentian is not a polyhydric alcohol, such as glucose.* In order to prove that this was the same sugar as exists ready formed in the root, I prepared a decoction of gentian, filtered, and tested as before with phenol-phthalein and borax; obtaining the same result. The remainder of the deposit was washed with strong, hot alcohol, and the alcoholic solution evaporated to dryness. The residue was too minute for examination, but had the appearance of an oily resin, which formed a yellow solution with caustic potash. It had no bitter taste. After washing with alcohol the residue consisted of albuminous matters and starch mixed with tow. Starch and gentian sugar, mixed with albuminous matter, are, therefore, the constituents of the deposit of tinct. gent. co., the first having no doubt slipped through the filter, as starches frequently will.

Tinctura Ipecacuanhæ Concentrata.—This is not an official tincture, but as it is somewhat largely used in some parts of the country, I have examined it qualitatively for emetine. After washing with weak spirit, it was dried, mixed with milk of lime and again dried, warmed with chloroform, the solution filtered and evaporated on a water-bath. Scarcely any residue was left, and on treating with calcium hypochlorite and acetic acid no yellow colour was produced, indicating absence of emetine.

Tinctura Lobeliæ Inflatæ Ætherea.—This deposit occurred as a somewhat flaky, white sediment; it does not occur in the tincture made with proof spirit.

It was first washed with spirit of ether, and shaken up with water, the aqueous liquid tested by Mayer's reagent for the presence of alkaloid, but found to contain none, and on boiling the deposit with water no odour of lobeline was developed, even on the addition of ammonic hydrate. After boiling, the deposit assumed a resinous appearance, and was of a greenish-white colour. Some of this resin (?) was treated with caustic potash, but was insoluble; it dissolved perfectly in ether, from which solution it was precipitated by alcohol as a nearly white resin (?). Benzol, chloroform, and bisulphide of carbon also dissolved it freely. It gave no characteristic reaction with any of the ordinary reagents for resins.

Tinctura Quiniæ.—The sample of tincture from which this deposit was obtained was not prepared according to the official directions, but the quinine was dissolved in the tincture of orange by the aid of a small quantity of acid. It was white and soluble in water; on examination it proved to be sulphate of calcium.

Mr. Hustwick has shown (*Pharm. Journ.*, [3], iii., p. 722), that this deposit is formed during the three days used in its preparation by the pharmacopœial method, and that another deposit is formed subsequently at low temperatures, consisting of tannate of quinine. I have not been able to obtain any of this latter deposit.

Tinctura Rhei.—The deposit, which was of a greyish-brown colour, was washed with proof-spirit as before, until the washings ran through only slightly coloured, then dried and extracted by benzol, first in the extraction apparatus, and then by boiling. A yellow solution was formed which on evaporation left a residue too small for further purification and was, therefore, weighed as slightly impure chrysophanic acid. 1·485 of a gram yielded ·018 of a gram of chrysophanic acid = 1·2 per cent. This residue was shown to consist of chrysophanic acid by yielding a fine rose-coloured solution with dilute ammonia, which solution gave a lilac to rose-coloured precipitate with acetate of lead.

The remaining portion of the deposit was boiled with water, and, as it still gave evidence of the presence of chrysophanic acid, was boiled with very dilute ammonia until exhausted; the ammoniacal solution filtered, washed, and shaken with chloroform after acidulating with acetic acid. The chloroformic solution was evaporated to dryness and the residue weighed ·0142 of a gram = ·96 per cent., which, with that already obtained, equalled 2·17 per cent. of chrysophanic acid in the deposit.

The residue after the above treatment was now washed with dilute hydrochloric acid, and the solution gave evidence of oxalate of calcium in considerable quantity. Another portion of the deposit, ·5634 of a gram, was therefore taken and the ash estimated by ignition, it corresponded to 29 per cent. of the deposit, and consisted chiefly of carbonate of calcium, due to the decomposition of the oxalate, also a small quantity of magnesium, but no potassium. The deposit in tinct. rhei therefore contains 2·17 per cent. of chrysophanic acid and about 37 per cent. of oxalate of calcium. I had not enough of the deposit to test it for cathartic acid, which is the purgative principle of the drug. The remainder, apparently, consisted of gummy matters.

Note.—It will be observed that no reference is made to the *amount* of deposit formed in the above tinctures, I had the opportunity of judging roughly in a few only, viz:—Tinct. cinchonæ, ¼ oz. from ʒ gallon; do., ʒj. from 1 gallon; tr. calumbæ, ℥iss. from 1 gallon. I should be glad to receive any deposits, especially those from the more potent tinctures, for further examination.

* See *Pharm. Journ.* [3]., vol. xiv., p. 41; Dunstan on Polyhydric Alcohols.

SKETCHES OF TYNESIDE TECHNOLOGY.*

BY B. S. PROCTOR.

(*Concluded from page* 467.)

It was greatly to the advantage of the Newcastle Chemical Society that its meetings were held in the rooms of the College of Physical Science, and that so many of its meetings had the benefit of interesting matters brought forward by Professors Marreco and Herschel. Among such occasions we may call to mind the exhibition in operation of Tyndall's arrangement for experimenting on the preservation of organic fluids in a moteless atmosphere, and at a later date, the apparatus for liquefaction of gases as planned by M. Cailletet and it is interesting to note now in passing the further steps which have been successfully taken in that direction by Wroblewski and Olszewski, as reported in the *Philosophical Magazine* for July last, and other periodicals, where we find described the means by which they reduced oxygen, nitrogen and carbonic oxide to the liquid state and alcohol and carbon disulphide to the solid condition. The reduction of temperature necessary for liquefying oxygen was obtained by the vaporization of liquefied ethylene *in vacuo*, the thermometer falling by this means to $-136°$ C. The liquid oxygen thus obtained was colourless, transparent, and mobile; nitrogen and carbonic oxide only liquefying at a lower temperature obtainable by a partial releasing of the pressure of 150 atmospheres to which they had been subjected at the temperature of $-136°$ C. Alcohol becomes viscid like oil at the temperature of $-129°$ C. and solid at $-130{\cdot}5°$ C.

One of the most prominent, and I think we must also say one of the most important, of chemical subjects in recent times has been that connected with the germ theory of disease and of organic decomposition—as yet a theory, but becoming more and more definitely accepted, and held to be the best explanation of the phenomena observed. This topic was first introduced to our meetings by Mr. Bell, in his address in 1868, in connection with the action of air in starting the crystallization of supersaturated solutions. Attention was again drawn to it by Mr. Glover, in 1870, urging the importance to be attached to the pollution of air by sewage gas and the pollution of water by drainage. Still more forcibly was the subject elucidated by Professor Marreco, in his presidential address in 1876, when some of Tyndall's experiments on a moteless atmosphere were repeated, and the results exhibited showing that not the air, but the motes, established the putrefaction, and by implication not the stench, but the germs, spread the disease. From that time to this the medical periodicals have been full of disease germs, and swarming with infusorial life. The battle of the bacilli has been continually before us, and is growing in strength. We are endeavouring to combat the germs of disease by cultivating the disease of germs; we are learning to destroy their virulence by having recourse to circumstances which prevent their healthy development, such as fresh air and antiseptics. The conditions of health of one organism are often the conditions of disease of another. The animal and vegetable kingdoms are complementary to one another, the one living upon the product of the other; and the kingdom of the microdemes, occupying a debatable ground between the other two, preys upon both. What is healthy to the higher organisms is deadly to the low; what is healthy to the low organisms is deadly to the higher.

There have been many workers in this field, the most prominent of whom is Pasteur, who within the last few years has developed the cultivation of *microbes* into a scientific operation. He has successfully brought under control the development of germs of varying degree or of constant degree of virulence, his first great achievement being in relation to chicken cholera and splenic fever. From his observations on the *microbes* which cause these diseases, a process of starving, of over-populating the medium in which they live, of giving them too little pabulum and too much fresh air, causes the degeneration which enables them to produce only a milder form of the disease, or no disease at all. He notes that a virulent father begets a virulent son to the thirtieth and fortieth generation, and that the modified father begets a modified son with the same regularity. He modifies the fathers of his races by giving them limited chicken broth and more fresh air than is good for them.

Probably when we suffer from zymotic disease abundance of fresh air not only raises our vital powers, but depresses those of the germs by which we are surrounded and inhabited. In a subsequent paper Pasteur speaks of the conditions which determine an epidemic, being the greater than usual abundance of germs. But the greater abundance of germs at any given time must depend upon a cause, the cause itself probably being a combination of circumstances favourable to the existence of germs and unfavourable to the health of man. Though we may readily admit that the more germs the more probability of any individual exposed to them being affected with disease, we must also add, the longer the individual is exposed to them the more likely is he to suffer. Take, in illustration, the advent of a zymotic disease in a family of children. When once present why do they not all follow in a body rather than taking it one by one, as we so frequently notice, spinning out the disease for several months? Probably the most susceptible take the disease first, and the less susceptible follow in order of their power of resistance, one being able to resist the inroads of the *microbes* for a month, another for three months, and it may be some have the vital vigour to digest the *microbes* without suffering in consequence. Though Pasteur modified his virus by the action of time and air, it is not to be supposed that oxygen is the only agent which can reduce their virulence. It is unquestionably the most important agent, and one that should never be neglected. The ventilation of sick-rooms and the ventilation of sewers are duties owed by every individual and every corporation to the health of the community, but a more radical change is probably required before the battle of the bacilli can be terminated in favour of man.

It is not safe to conclude that a nuisance hidden, an evil smell got rid of, has removed the danger. Pasteur found that an animal which had died of splenic fever, and had been buried for twelve years, had so infected the soil that the worms would bring the virus to the surface and communicate disease to cattle feeding there. The soil does not admit of so free an action of the oxygen as to take away the toxic power of the germs. There is reason to suppose that most soil which is impregnated with decomposing organic matter is also infested with microzoa or germs, more or less inimical to the higher forms of animal life. There have been many cases noted in which the prevalence of disease would appear to be dependent on the newly-opened surface of the earth. For example, the new streets are more visited by the doctor's carriage than those of the same character of ten years' earlier date. If the probability of such a connection between the soil and disease be kept in view, evidence will soon be found to determine whether or not they stand in relation of cause and effect; and if it should so prove, the chemist, the biologist, and the architect will have to unite their powers to protect us from our common enemy. Cold, dryness, and fresh air are conditions under which the developed microzoa have little chance of life; but these conditions do little injury to the germ in its condition of potential life, and, indeed, dryness and ventilation promote the diffusion of the germ-dust, while warmth, moisture, and a limited ventilation are all that are re-

* Address delivered on October 4 to the Newcastle Section of the Society of Chemical Industry on the occasion of the opening of the Session 1883–84.

quired to start an active condition of vitality; and if there be present organic matter, living or dead, these are the conditions which produce disease in the one case or putrefaction in the other, provided there be not present at the same time some antiseptic, some substance which is poisonous to the microzoa. To get rid of the risks involved by the presence of these germs, probably a long-continued action of air, light, and dryness would suffice. Probably a short time would suffice to accomplish disinfection if the circumstances were so arranged that germs should germinate, but that the life so developed should not be vigorous enough to permit of reproduction. The circumstances under which it is possible to insure complete disinfection of organic materials by the agency of dry heat are not always permissible. We may put many articles of clothing, etc., under the necessary treatment, but we cannot subject a traveller or a patient to more than a figurative roasting or stewing, consequently the conditions of quarantine are so prolonged as to give time for germs, if present, to develop active life, or to work out the complete cycle of their consequent disease. It would be an interesting work, both in relation to the mitigating of individual attacks of zymotic diseases and reducing their liability to spread, to classify all the substances which can be found with the power of modifying the virulence of germs, with the view of finding such as might impregnate the human system without danger, and so reduce the duration and diminish the severity of the attack. Probably the action of quinine in malarial fever is of this nature, and, as in many other cases, the fact is known before the reason is understood; but if the reason of its efficacy be once understood, or even suspected, the active search among chemicals should begin by experimenting upon the infusoria, our enemies, who are below the protection of the Vivisection Act; and guided by the evidence so obtained, the experimentalist might go to the other extreme and try the effect of his chemicals upon ourselves, who are above that protection.

With regard to the supplying of pure air and pure water, pure as regards freedom from germs, one point has struck me very forcibly, as it no doubt must have struck many others—that is, the great facility with which air is filtered and rendered pure by filtration through a mere loose plug of cotton wool, and how the most careful filtration fails to do as much for water. Mr. Dallinger some time ago informed me that he thought it was practically impossible to free water from germs by filtration; and Frankland's experiment, quoted to us by Professor Marreco, in his presidential address, in 1876, showed that water might be filtered through a mile or two of soil and still carry with it the germs of disease.

There are two or three points in the physics of filtration which tend to this result. First, the greater the difference in density between the suspended matter and the fluid, the greater the facility for the separation, and the greater the mobility of the fluid, other things being equal, the greater the facility for separation. Both these act in favour of atmospheric filtration. In addition to these, there is the difference between the case of atmospheric germs and infusoria in an active condition: the former are carried by currents of air without any guiding power of their own, while the latter move in water not only in the direction of its currents but with a guiding power of their own. The channels in filtering media are generally so large that finely divided solids could pass through them, and would pass through them if suspended in viscid liquids. Why do the same powders not pass through when suspended in mobile liquids? A solid particle moved by a current of liquid less dense than itself acquires the tortuous motion of the current in a reduced degree, the curves being more gradual and the angles less sharp. The liquid impinges against the cotton filament of the filtering paper and turns aside, but the solid impinges there and is deposited upon it. In filtering water through paper, probably only one molecule in a million touches the paper: the molecule in contact with the filament forms a buffer to pass the others on without actual contact. As they have no greater density and no greater velocity, they have not power enough to move a molecule which is attached, but a particle of more dense matter has a momentum carrying it on in a continuous direction with a force greater than enough to remove the intervening molecules of water. Thus very few particles of solid matter suspended in a mobile liquid of little density pass through a medium the pores of which are large enough to allow of the particles passing freely through if suspended in a viscid liquid. Probably we rarely meet with filtering media the pores of which are so fine as not to afford space enough for the passage of finely-divided solids. Finely powdered chalk suspended in ether, a liquid lighter and more mobile than water, is perfectly separated by filtration through paper; chalk suspended in chloroform, a liquid heavier and more mobile than water, is likewise completely separated; though chalk suspended in water partially passes through the same paper, and if 1 or 2 per cent. of gum be added a considerably increased portion of the chalk passes through the paper. If the explanation of these differences be as I have suggested, we can readily understand how bacteria of exceeding minuteness, of a specific gravity almost identical with water, and having vital motion of their own, escape entanglement in the coarse meshes of paper filters or the open pores of the charcoal blocks.

It is well to remember, not only in connection with the treatment of disease, but in connection with wholesome air and water, that a little change may make the nidus of a germ favourable or unfavourable to vigorous germination, and what is favourable to one species of germ may be the reverse to another species; also that the race which is under adverse circumstances may be eaten out by the most favoured nation of microzoa. Well for us if that nation be more favourable to humanity. Filtration of water through charcoal may fail to mechanically arrest bacteria, but it may still deprive them of their sustenance and in a measure of their virulence. The observations of Pasteur and Frankland would lead us to suppose that sewage irrigation, if ever it is to be adopted successfully and safely, must depend for its safety upon the free action of air causing such degeneration of the microbes as to deprive them of their power to propagate disease. If the burying of a diseased carcase be simply planting a mine of disease, prolific for years afterwards, where is the safety of spreading the sewage of a diseased neighbourhood upon the land? We could only hope to escape evil consequences from the natural disinfecting power of the air, which may be supposed to act upon the soil to the depth which is necessary for keeping the herbage clear of dangerous germs.

With so much evidence of a conflicting character as has been published regarding the disposal of sewage, the ventilation of drains, etc., it is satisfactory to find that the Registrar-General reports an improved sanitary condition of the country during the ten years from 1871 to 1881 when compared with the period of the ten years preceding, the death-rate from general causes having been reduced by 5 or 10 per cent., but the death-rate from zymotic diseases having fallen in a much greater ratio, the deaths from enteric fever being reduced to two-thirds, the deaths from typhus and continued fever being reduced to less than half, and the fatality of other infectious diseases being reduced in an important though less striking degree. Such facts encourage us to continue the work of sanitation upon the same lines, or upon other lines which will still more effectually represent the logical deduction from the data established. Can we educate the microzoa into the principles of vegetarianism? Can we teach them to be herbivorous, and no longer to prey upon their neighbours in the animal kingdom? To do so, we must banish putrefaction from the animal kingdom, cremation must take the place of burial, and not of burial only but of sewage also. Before we can do this we must educate not the bacteria but society. The individual must learn to do no injury to his neighbour either in life or death; nor should his feelings, his sentiments regarding departed friends, stand in the way of his doing his duty towards those who remain. Good would result not only from the substitution of cremation for the burial of the dead, but from requiring every species and every fragment of putrescible animal matter to be treated in a similar way—to be put under the protection of antiseptics till the quantity had so accumulated as to be worth submitting to destructive distillation.

The advance of chemical technology is not indicated only in such changes as the Leblanc soda being pushed aside by that made by means of ammonia, or puddled iron disappearing in presence of Bessemer steel, though the latter is more typical than the former of the genius of the times. Chemical manufacture has now ceased to have the limited meaning that was formerly attached to it—it is no longer "The Alkali Trade" with a few etceteras. Chemical law now reigns in many works which were formerly ruled by thumb. Organic chemistry now holds a position as important as that of the less delicate operations upon simpler compounds. The collateral sciences are becoming more and more closely allied to chemistry, giving and receiving impetus from one another. The progress of electroplating has developed the uses of nickel, and will probably do the same for other metals. The demand for electrical storage is developing the chemistry of lead, and can scarcely fail to have a like effect in other directions.

The Siemens regenerative furnace has as yet done only a small portion of the work it is fitted to perform, and it is only one phase of the use of gas as a source of heat. The first fruits of electric lighting are a crop of improvements in gas-lighting, and if its last fruits should be the extinguishing of gas as an illuminant, that will be accompanied by an encouragement of its use as a heating agent and a motive power. The gas engine compared to the steam engine is a shortening of the process by which chemical action is converted into mechanical force, and it will no doubt be followed by further steps in a similar direction. It will probably urge on the improvement of the steam engine, or displace it from certain portions of the ground it now occupies, perhaps also leading the way to other modes of developing mechanical force from chemical energy. The conversion of one kind of force into others is an art of recent times, and of great promise. We are almost ceasing to use arrangements of metals and acids for the production of electric currents, and are learning to use electric currents for smelting or melting metals, and patenting arrangements by which the electric current converts air into nitric compounds. I have not hesitated to assume the existence of vital force, an agency to which I attach considerab e importance, but which some chemists of an advanced type say is resolvable into chemical affinity, an electric current and the process of dialysis. To say that the products which were formerly only produced by vital action are now obtained by a series of syntheses from inorganic or simple bodies is not sufficient ground for dismissing from our calculations a force, vital force, which we do not understand, and into which we cannot convert other forces. Nothing is more tempting than to gaze into the deeper depths of Nature's mysteries, and past experience all teaches that we shall reap benefits from the search, whether or not we find that which we seek. There is probably no more wisdom now in denying the possibility of a microdeme coming into existence without a parent than there was fifty years ago in denying the possibility of starch being formed otherwise than in a plant, or urea without a kidney. It is not necessary in acknowledging the existence of a Creator to suppose that he has ceased to exert creative power.

IMPROVED METHOD OF EXHAUSTING DRUGS.*

BY ALFRED B. TAYLOR.

For some years past I have employed a process for making some of the fluid extracts, tinctures, etc., of the Pharmacopœia, which has proved very satisfactory. The plan has probably occurred to others, but I have never seen it published, nor have I ever heard it suggested by any one, and I have thought a notice of it might be acceptable to the readers of the Journal.

I have found it especially serviceable in making those preparations which are made from drugs that are difficult to exhaust with small quantities of menstruum.

The process consists in using a portion of the finished preparation (from a previous operation) to macerate and partially exhaust the drug before using the new portion of menstruum, and as there is no limit to the quantity of finished preparation that can be used where necessary, it is prossible to exhaust completely the drug operated on.

For example, let it be required to make two pints of tincture of arnica flowers.

Take of—

Arnica flowers, in No. 20 powder . .	6 oz. av.
Tincture of arnica flowers	2 pints
Diluted alcohol, a sufficient quantity to make	4 pints.

Moisten the powder with a pint of the tincture of arnica flowers, and macerate for twenty-four hours; then pack it firmly in a cylindrical percolator, and gradually pour upon it, first the remainder of the tincture of arnica flowers, and afterwards diluted alcohol, until four pints of tincture are obtained.

I have used this process with great advantage in making the fluid extract and the tinctures of cinchona.

CHAMPAGNE MAKING IN FRANCE.†

In the champagne district the greatest attention, says Consul Frisbie, is paid to the picking of the grapes, the fruit being supported in the left hand so as to prevent the riper grapes from falling, and care being taken not to bruise the fruit in throwing it into the baskets. These baskets, when full, are emptied into larger ones, and minutely examined, in order that all the bruised, rotten and unripe grapes may be removed. If the grapes are very ripe, wisps of straw are placed in the bottoms of the baskets to prevent jolting and bruising. The picking usually commences with daylight, and the vintagers assert that the grapes gathered at sunrise always produce the best wine, and that by plucking the grapes when the early morning sun is upon them they are believed to yield much more juice; later in the day, in spite of all precaution, it is impossible to prevent some of the detached grapes from partially fermenting, and this frequently has the effect of imparting a slight excess of colour to the must. The gatherings of one day are pressed the following morning, the operation being effected by means of presses of different kinds; the most ancient being the *cliquet*, which is largely used at the present day. It is worked by a roller and grinders—large pieces of wood which are placed in layers on the pressed grapes. The grapes are spread over the floor of the press in a compact mass, only the first pressure producing a high class wine. Before beginning to press, the grapes are weighed, and 400 kilograms are allowed for every 40 gallons of wine, and this having been obtained, no more is pressed from it for first-class wine. The remainder then consists only of a heap of crushed fruit. The edges of this heap are next cut off in various

* From the *American Journal of Pharmacy*, November, 1883.

† From the *Brewers' Guardian*, November 6, 1883.

ways according to the shape of the press, the edges having been subjected to less pressure than the middle. The grapes thus obtained are then subjected to a second pressure, which produces a juice called first *taille*, and this operation is repeated to get a second *taille*, and a third time for the last juice, called *redeche*, a production which, in the champagne country, is only used for the consumption of the labourers, as is also the case with the produce of the second *taille*. When the wine is flowing from the press, the juice is tested with a wine tester or glycometer, to ascertain its sweetness and the amount of sugar it contains. Then, when the wine is drawn off from the press, it is put into tubs or casks, and is left until the impurities, thrown off, have collected on the surface in the shape of a scum, called *cotte*. As soon as this scum rises to the surface, the casks are filled and vapoured by burning sulphur. This operation, setting free sulphurous acid, tends to whiten the wine and prevent the taste of oak from flavouring it. The casks are then placed in the cellar on supports, usually about 8 inches above the ground, care being taken not to fill them quite full, as, when fermentation begins, they would overflow. A margin of several quarts is therefore left, and the bung is closed with vine leaves and a small tile. After a month has elapsed, and the fermentation subsided, the wine is racked off into other casks by means of copper basins and vessels. With the approach of December comes the frost, which makes the wine quite clear; it is at this period that the mixing is performed, an operation which immediately precedes the blending. The mixing consists of bringing together thirty or forty casks of the same growth. The blending, on the other hand, is the mingling of all these wines, with a view to the formation of a large quantity of wine for commercial purposes. It is at the blending time that the tannin is used, in liquid or powder, to anticipate various defects in the wine, such as grease and deposits. These deposits are known in the wine district by the technical names of *marques*, *barnes*, *culs de poule*, and *lentilles*. It is at this time also that alcohol, in greater or less proportions, is added. The wine merchants find the degree of alcohol by distilling a given quantity of wine, of which they take a third, and mix the result of the distillation with some distilled water, weighing with an alcoholometer, and taking into consideration the degree of temperature. Champagne wines generally have from 11 to 12 per cent. of alcohol; but in some very good years, such as 1865 and 1874, as much as 14 per cent. If the year should be a poor one, and the degree of alcohol insufficient, it is remedied by adding a sufficient quantity of spirits of 82°, made from the best Cognac brandies. The day after these operations have been completed, the fining is commenced, and this is done with isinglass, prepared beforehand with a slight admixture of tartaric acid. Every cask of white wine receives a slight proportion of this mixture, and is stirred with a stick before and after mixture, this being done with the object of thoroughly mixing the wine and isinglass. The casks are then hermetically sealed, a small hole being drilled in the top of the cask, and closed with three straws of rye or wheat, with the heads on; this admits sufficient air to remove all danger in case of fermentation. The wine remains in this state for about a fortnight or three weeks. When the wine is ready for bottling, the operation is effected by means of taps with six, eight or ten spouts. The bottles when filled pass into the hands of the corker—the corking being done with a mallet, and the cork secured. The bottles are then stored in the wine vaults, or left in the cellars, where they are stacked with rods and laths. In the month of July, when the bottling is over, the workmen find employment in removing defective hoops, or replacing them by new ones, and this operation, with the vintage, continues till the time of early frost. At this time many vineyard proprietors bring what they have bottled up again to the upper cellar, as the cold has the effect of helping the deposit to dry. Others simply change the position of the bottles, removing the leaky and broken ones, and making new piles. It is at this time also that attention is paid to the *masque*, the name given to the deposit on the side of the bottle, and which must be removed. This is done by means of a machine, which consists of a box, into which are placed two bottles having the deposit in them; by means of a handle a rotary motion is imparted to the bottles, which are further subjected to continued blows from two little hammers. These continued shocks produce a shaking, which is sufficient to detach the adhesive deposit. The removal, by hand, requires more attention. The workman is supplied with an iron implement, and has to be careful to hit the bottles just hard enough to detach the crust. When the bottles are entirely cleared of deposit, they are placed neck downwards, either on tables or on racks, and after being kept for some time in this position, the wine is shaken to make all the deposit fall on the cork. This is an important operation, and great care is taken in the selection of workmen to perform it. It is effected by very slightly lifting the bottles, and gently shaking them in that position. To bring it to a successful issue, requires a month or six weeks, or even more, the bottle being moved every day. When the deposit has altogether settled on the corks, the good bottles are placed in stacks, with their necks downwards, at a sharp angle, to await the time when they are again uncorked. The rest are replaced and worked a second time on the rack. The uncorking is also a difficult and delicate operation. It is necessary to remove the cork and wiring with the least possible loss of time, the bottle being all the time kept neck downwards. To do this, the workman watches the bubble of air which is in the bottle, and so removes the cork that only the deposit is ejected by the rush of gas. When the froth appears he uses part of it to wash the neck of the bottle, and then inserts a small cork prepared for the purpose, which prevents too great a loss of gas. The bottle then passes into the hands of a man who takes out enough wine to admit the necessary amount of syrup. The wine is now very dry, and would not be drinkable; this dryness is, however, corrected by the addition of what is called the "export syrup," which differs from what is put in at the time of bottling. It is composed of 150 kilograms of candied sugar to every 100 litres of wine, and 3 quarts of alcohol added to increase the strength. As the sugar dissolves the wine become thick, and must be filtered to make the liquid perfectly clear. The bottles when opened and emptied to a certain depth, are taken to the "mixer." The mixing consists in putting into each a certain equal quantity of syrup, the precise proportion differing for each country; the bottle is then placed on a revolving table, and as it revolves, all the bottles in turn come to the corker. The second and final corking requires more care than the first. The corks used are made from Spanish cork, soft or strong, hard and full, or red corks, according to the country to which the wine is intended to be sent. They are soaked for a few days in cold water before being used. For the final corking the machine used is often a mallet machine, but others are employed. The cork is put into a tube, pressed, and made to come level with the lower end of the tube, and with a clean sponge the few drops of water which have resulted from the compression of the cork are wiped off, and the bottle is then filled and corked, the cork being driven in to a greater or less extent according to the destination of the wine. The tying up is then proceeded with, oiled string being used. After the string is put on the wire is attached; the kind most in use being galvanized wire. It is at this time that the bottle is shaken once or twice, to mix the syrup thoroughly with the wine. Then the bottles are arranged in piles, always on end, and are left for a month or two. In conclusion, Consul Frisbie states that to make a good bottle of champagne at least two years of constant work and care are necessary.

THE CHEMICAL AND PHARMACOLOGICAL BEHAVIOUR OF FOLIA UVÆ URSI AND ARBUTIN IN THE ANIMAL BODY.*

BY DR. L. LEWIN.

Teacher of Materia Medica and Public Health in the University of Berlin.

I have given expression in my experiments with the leaves of the uva ursi, to the desire which has characterized pharmacology of late years of substituting the active principle of vegetable drugs for the drugs themselves, when seeking to secure the therapeutic effects of the latter. I have been induced also in so doing by a desire to determine the precise principle to which the action of this drug, which has for over a hundred years been employed in medicine, is due, and the changes which it undergoes in the system. Bright recommended the drug as a diuretic in the disease to which his name has been given, and now specific properties are claimed for it in catarrh of the bladder. Wherein lies this therapeutic property? The leaves yield tannin, gallic acid, urson, and the glucoside arbutin. The therapeutic properties of urson are not to be considered, inasmuch as this substance is not soluble either in water, dilute acid, or alkalies. Arbutin is soluble in water, has a bitter taste, and is decomposed by boiling with acids into sugar, methylhydrochinon, and hydrochinon. It does not ferment with yeast. It possesses, as I discovered, the property of rotating the plane of the polarized ray to the left. I also discovered that neither animal nor vegetable charcoal separates arbutin from either a warm or cold solution. A decoction of the leaves of uva ursi rotates, according to its strength in arbutin, the plane of the polarized ray to the left. The hydrochinon is optically inactive. I prepared the latter from the leaves as follows:—

Infusion of the leaves was precipitated with basic acetate of lead, the filtrate freed from excess of lead by means of sulphuretted hydrogen, and the resulting concentrated filtrate boiled for some time with dilute sulphuric acid. From the resulting dark-brown solution ether separates hydrochinon, which, on evaporation of the ether, is deposited in beautiful crystals.

There are two possible methods in which the leaves of uva ursi may act, namely, through the arbutin or the tannic acid which they contain. I have established by experiments the action and disposition of arbutin in the animal organism. It is manifest from these experiments that when arbutin is introduced into the system, either hypodermically or by the month, it is split up, a process which is demonstrable outside of the body, by boiling. There appears in the urine a substance which, on a brief exposure to air, changes to an olive-green or brownish colour. This substance is hydrochinon, as may be demonstrated to a certainty. These changes are also observed in the urine of man after the exhibition of uva ursi leaves. At first the urine is of a bluish-green colour, but after standing from twelve to twenty-four hours, it becomes of a somewhat darker green; then olive-green, and later brownish-green. It also happens that that which, when voided, is of a greenish-brown, afterwards becomes of such a dark green as to lose its transparency. With the onset of the dark discoloration the acid reaction of the urine diminishes, and it finally becomes alkaline.

The chemical process of this is as follows: The arbutin is converted into hydrochinon, and the latter is in turn converted into sulphate of hydrochinon. On standing exposed to the atmosphere the hydrochinon sulphate may, through the gradually growing alkalinity of the urine, be split up and the free hydrochinon further oxidized into products not definitely known. When the urine has already become alkaline in the bladder the process above described takes place in the bladder, and the urine is voided of an olive-green colour. But the whole quantity of arbutin taken into the system is not decomposed into hydrochinon and sugar. I have shown that a portion of this is voided unchanged in the urine.

Arbutin is not poisonous. It does not, through splitting up, set free in the body a sufficient quantity of hydrochinon to have a poisonous action.

As touching the action of uva ursi leaves and their different medicinal preparations, I have demonstrated by experiments, in the human being and lower animals, that the chemical changes are identical. In these experiments are also usually observed a progressive dark discoloration of the voided urine, proportioned to the amount of hydrochinon which is traceable. This is, however, not always the case, as has been taught in practice. It is to a secondary degree dependent upon the size of the dose administered. It is to a greater degree influenced by the condition of the urine. When uva ursi leaves are administered in vesical catarrh, attended by an ammoniacal condition of the urine, the latter is discoloured to a greater or lesser degree. The rotation of the polarized ray to the left shows also the presence of unchanged arbutin in such urine.

With these results as a basis, it is not difficult to establish the fact that the substance to which uva ursi leaves owe their reputation for specific action in vesical catarrh is hydrochinon. An auxiliary, although as compared with hydrochinon an insignificantly small action, is due to tannin, which is contained in the decoction of uva ursi leaves, and is voided in a very small amount in the urine.

Hydrochinon possesses antizymotic and antiseptic properties in even a one per cent. solution. I found that urine which had been voided after the administration of uva ursi leaves remained fresh, even after standing in the open air for two weeks, while that subsequently voided rapidly decomposed.

Hydrochinon possesses, particularly when it has become dark in solution, an irritating property. This irritation is, however, directly beneficial in catarrhal affections of the mucous membranes, which become turgid thereby, and have set up in them reparative action.

It is, therefore, to the antiseptic and irritating property of hydrochinon that the therapeutic action of uva ursi leaves is due.

It follows from this that much larger doses of uva ursi should be given than have heretofore been customary, inasmuch as even if the decomposition of one gram of arbutin into hydrochinon and sugar were complete, which is never by any means the case, the amount of hydrochinon which would thus be generated would be too small to secure the most beneficial local action on the bladder. In addition to this is the fact that the amount of arbutin contained in uva ursi leaves is very small. It is recommended, therefore, that when uva ursi leaves are administered, a decoction of from 30 to 80 grams in 180 grams of menstruum should be given. The objection which the large amount of tannin might interpose to the administration of such a decoction can be overcome by agitating it with charcoal:—

℞ Decoct. fol. uvæ ursi, 30—80: 180 grams.
Agita c. carbone vegetabil., q. s. ad remov. acid. tannic.
Filtra. S.

For this purpose I should regard the substitution of arbutin for the decoction as an improvement, should arbutin in the future take the place of the leaves themselves in medicine. Arbutin may be ordered in the form of powder or in solution; for instance:

℞ Arbutini . . . . 1·0 gram.
Sacchari . . . . 0·5 gram.
M. Ft. pulv.

Or,

℞ Arbutini . . . . 5—10·0 gram.
Aquæ dest. . . . . 100·0 gram.
M.

It may also be given hypodermically.

Clinical experiments have in the meantime demonstrated the fact that arbutin is a valuable therapeutic agent.

---

* From the *Therapeutic Gazette*, Sept. 15, 1883.

The Pharmaceutical Journal.

SATURDAY, DECEMBER 22, 1883.

Communications for the Editorial department of the Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

CHINOLINE DERIVATIVES AS ANTIPYRETICS.

THE attempts to find efficient substitutes for the febrifuge alkaloids of cinchona bark, which for a long time were made principally in the vegetable kingdom, have during the last two or three years been taking a somewhat less empirical form, and although chemists have hitherto failed actually to build up the invaluable alkaloids in their laboratories, they have, while continuing the work in that direction initiated many years ago by Professor A. W. HOFMANN, quite recently succeeded in producing several definite chemical bodies which have been proved by experiment to possess more or less of their therapeutic properties. The synthetical formation of chinoline, itself a decomposition product of quinine, by Herr SKRAUP about three years since, gave a considerable stimulus to hope in this direction, and that base, together with some of its compounds with acids, acquired at least a temporary reputation as quinine substitutes. But chemists did not consider the goal to have been yet reached, and an investigation carried on by Professor FISCHER, of Munich, in conjunction with Herr RIEMERSCHMIED, and another by Messrs. HOFFMANN and KÖNIGS, have led to the preparation of a large number of new derivatives from chinoline, descriptions of which have been communicated to the Berlin Chemical Society. Some of these compounds have already attracted considerable attention from the medical profession on account of the antipyretic action upon the organism that has been attributed to them, and at least one of them is now used to some extent as a medicine. It seems to us, therefore, that it would be convenient to publish in these columns, for the benefit of those of our readers who are prevented from following step by step the records of chemical investigation as they appear in the technical journals, a very brief *résumé* of the chemical history of a few of these chinoline derivatives, concerning which they are at any time liable to be asked for information. This course might also prove to be the more desirable, since already some of these compounds, in order to avoid the intolerable inconvenience attached to their lengthy and uneuphonious systematic names, have had other designations applied to them, which are arbitrary and disclose nothing as to their composition. A number of chinoline derivatives have also been prepared which are at present only of interest from a chemical point of view; but it is proposed to refer to this latter class only so far as is necessary to make clear the relation of the compounds that are of possible therapeutical importance.

The compounds described by Herr FISCHER are all of them derivatives from what he calls α-oxychinoline, and those described by Herr RIEMERSCHMIED are derivatives of β-oxychinoline, which two bodies appear to be identical with those that Herr SKRAUP has designated ortho- and meta-oxychinoline. These two oxychinolines are obtained by fusing with an alkali the corresponding sulphonates of chinoline, both of which are produced by the action of Nordhausen sulphuric acid upon chinoline, the α-sulphonate predominating when four parts of acid are used and the temperature does not exceed 200° C., and the β-sulphonate when the temperature exceeds 270° C. or the proportion of sulphuric anhydride is increased. Upon treatment of these isomeric oxychinolines with tin and hydrochloric acid there are formed double salts of tin and corresponding tetrahydro products, which have been termed α- and β-oxyhydrochinoline. These secondary bases can be converted into well-characterized tertiary bases by the introduction of a methyl, ethyl, benzyl or other alcohol group, and in some instances the product is a compound of therapeutic promise.

The first to be mentioned is α-oxyhydromethylchinoline, which is formed by the reaction of iodide, bromide or chloride of methyl upon α-oxyhydrochinoline. It is a strong base, readily soluble in caustic alkalies, with difficulty in water, and freely in benzol, warm alcohol and wood spirit. From ether it crystallizes in colourless, usually tabular crystals of the rhombic system, and from alcohol it is, as a rule, obtained in prismatic crystals. This methyl compound is distinguished by the following reactions. A diluted sulphuric acid solution gives with sodium nitrite an intense beautiful red-yellow colour; sodium carbonate throws down from the yellow solution a yellow-brown flocculent precipitate. A single drop of ferric chloride produces in a cold alcoholic solution a deep brown colour, the liquid then becoming turbid and separating dark brown flocks; an excess of ferric chloride colours the liquid a dark blackish brown. Ferrous sulphate produces in an alcoholic solution a transient dark red colour, and forms in a concentrated solution a dirty-looking precipitate. Potassium ferrocyanide produces in a very dilute acid solution an almost colourless voluminous precipitate, which dissolves in boiling water and crystallizes out on cooling in small bluish-green crystals. The melting point is 114° C., and analysis gave results corresponding closely with the formula $C_{10}H_{13}NO$. In the original paper of Herr FISCHER, the name "kairin" is applied to the hydrochlorate of α-oxyhydromethyl chinoline, for the sake of brevity; but, as will be seen by reference to a paragraph on p. 432, this is not the compound now sent out under that name by the patentees, which is presumably one of the ethyl compounds to be referred to subsequently. This salt of the methyl base is freely soluble in water, and upon evaporation of the solution over sulphuric acid is obtained in well-formed colourless shining crystals of the monoclinic system, the larger individual crystals readily becoming faintly violet coloured. The salt loses at 110° C. 8·27 per cent., or equal to a molecule of water of crystallization; and is represented by the formula $C_{10}H_{13}NO,HCl+H_2O$. The sulphate occurs in freely soluble flat shining prisms, and the picrate in handsome greenish-yellow shining tables, soluble with difficulty in water.

α-Oxydyhydroethylchinoline is prepared in a similar manner to the methyl compound. This base is easily soluble in benzol, alcohol, wood spirit and ether, very difficultly soluble in water and with some difficulty in light petroleum spirit. In other respects the behaviour of the ethyl base is analogous to that of the methyl base. In order to obtain it pure advantage can be taken of the hydrochlorate, which on account of its difficult solubility in hydrochloric acid is easily prepared pure. This hydrochlorate is called in Herr Fischer's paper, "kairin A." It crystallizes in magnificent brilliant colourless prisms and is easily soluble in water. When crystallized from hydrochloric acid the salt is represented by the formula $C_9H_{10}NO(C_2H_5)HCl$.

Another series of compounds described by Herr Fischer, one at least of which appears to possess important therapeutic properties, consists of derivatives of α-ethoxychinoline, a body obtained by treating α-oxychinoline in alcoholic solution with caustic potash and then with ethyl bromide. From this compound, by treatment with reducing agents, α-ethoxyhydrochinoline is obtained, and from this hydro base α-ethoxyhydromethylchinoline is prepared, by heating it with methyl iodide, as a pale yellow oil which does not appear to solidify and boils between 269° and 270° C. The salts of this base are crystalline, very soluble, and mostly deliquescent, and it is the acid sulphate, occurring in tufts of colourless prisms, that is referred to subsequently.

Turning now to the other series of compounds obtained in an analogous manner from β-oxychinoline, Herr Riemerschmied describes among them β-oxyhydroethylchinoline, the hydrochlorate of which is soluble with difficulty in water, and can be obtained in handsome white plates or tables. It has a pungent taste, subsequently becoming bitter, and according to Professor Filehne it resembles "kairin" in its physiological action. The salt is represented by the formula $C_9H_{10}NC_2H_5OHCl+H_2O$, the molecule of water being driven off at 110° C.

The investigation of Messrs. Hoffmann and Königs lay in a different direction, having been devoted to the production and examination of non-oxidized derivatives of chinoline. By the treatment of chinoline with reducing agents, as, for instance, hydrochloric acid and tin, two secondary bases may be obtained, one containing four and the other two atoms of hydrogen more than the original base. The former, tetrahydrochinoline ($C_9H_{11}N$), is of especial interest, on account of its probable near relation to the cinchona alkaloids. It possesses strongly basic properties and is liquid at ordinary temperatures, but when pure solidifies in the cold of winter to form colourless needles. It boils at 244° to 246° C., and distils without decomposition. Several of its salts and nitro-compounds are described by the authors, but need not be further referred to here. The experiments of one of the authors having led him to the opinion that cinchonine probably contains a nucleus in which a methyl group is united to the nitrogen of hydrochinoline, an attempt was made to produce such a compound, and methyltetrahydrochinoline ($C_9H_{10}NCH_3$) is one of two products obtained by the action of methyl iodide upon tetrahydrochinoline. After separation and purification by conversion into sulphate and decomposing, it appears as an oil, boiling at 242° to 244° C. Its salts are most of them deliquescent and are difficult to obtain crystalline. The acid sulphate forms white prismatic crystals, which readily deliquesce when exposed to the air. The corresponding acid sulphate of ethyltetrahydrochinoline, as prepared by Messrs. Hoffmann and Königs, behaves similarly. It is to these two acid sulphates, and especially to the first-mentioned, that the term "kairolin" has been applied.

The physiological experiments with these compounds were undertaken by Professor Filehne, of Erlangen. It was found that α-oxychinoline and methoxychinoline and their salts possessed poisonous properties, and attention was therefore directed to the hydro-derivatives. The hydrochlorates of α-oxyhydrochinoline and methoxyhydrochinoline showed indications of an action in the direction of quinine, but this was accompanied by other disagreeable effects, such as the local decomposition of albumen. As this local action was attributed to the atom of hydrogen loosely united to the nitrogen, it was sought to produce a more stable molecule by replacing it with a methyl or ethyl group and the hydrochlorate of the resulting oxyhydromethylchinoline ("kairin") was found to possess an extraordinary antipyretic property without the local inconveniences caused by the hydro bases. The β-oxyhydroethylchinoline and the α-ethoxyhydromethylchinoline were also experimented with, and found to exercise the quinine action, but differing in the degree of its persistence; in this respect the acid sulphate of α-ethoxyhydromethylchinoline exceeded all other substances examined, the effects continuing during fifteen or sixteen hours. As to the non-oxidized series, the hydrochlorate of tetrahydrochinoline is in its general action more energetic than chinoline, but cannot be used on account of its strong local action. The acid sulphates of methyl- and ethyltetrahydrochinoline ("kairolin") possess the property of reducing the fever temperature, like "kairin," and in the few cases in which they were used their action did not appear to be attended by unpleasant symptoms, such as singing in the ears, headache, etc.; but they have the disadvantage, as compared with "kairin," of being deliquescent and having a more acrid disagreeable taste.

It appears that we were somewhat hasty in assuming, in common with at least one medical contemporary, that drugs and medicinal preparations will be represented in the Health Exhibition to be held at South Kensington next year. In reply to a request for more definite information we have been informed by the Secretary—almost ironically it might be thought if it were not for his known courtesy—that "it is not intended to exhibit drugs or medicinal preparations, inasmuch as being a Health Exhibition these are outside its scope." Nevertheless, Class 30 is to be devoted to "Personal Hygiene and Care of the Sick." This official decision to the effect that there is no connection between drugs and medicinal preparations and the health of the public throws a new light upon the future of pharmacy and might be thought by some to render almost superfluous the projected issue of the two addresses of the late President of the British Pharmaceutical Conference on the future supply of drugs to the public.

* * *

We understand that in one of the outlying suburbs of London proceedings have been taken against several chemists and druggists under the Weights and Measures Act. We are not yet acquainted with the exact facts upon which the proceedings were based, but it appears that partly, at least, the offence consisted in being in possession of weights and measures that were not properly stamped. We have on several occasions pointed out that neglect to comply with the requirements of the law in this respect might be productive of annoyance and inconvenience.

* * *

A report has been published, wh'ch requires confirmation, that a tree yielding balsam of copaiba has been discovered in the Ghat forests of Coorg. The report seems to be based upon the observation that a tree having some resemblance to Mr. Cross's description of the genuine tree was found to yield a thick oily "claret-red" liquor, possessing the characteristic odour of balsam of copaiba, but in less degree. According to the *Indian Forester*, the leaves of the tree—no flowers have yet been obtained—resemble somewhat those of *Pterocarpus marsupium*, the source of East Indian kino, but are very irregular in size and shape. It is stated that samples of this liquid have been forwarded to this country, so that more information concerning it may be forthcoming.

* * *

A correspondent to the Ceylon *Tropical Agriculturist*, says: "It is, perhaps, not generally known that the young leaves of the lime have a pleasant, sweet, mucilaginous taste, if eaten raw or boiled as a vegetable, or used as a salad." He adds that he and his family have used them for years.

* * *

M. Jules Libert, a pharmacien of Liége, in a communication to the current number of the Brussels *Journal de Pharmacologie*, states that he has been recently supplied, by a wholesale druggist, with iodoform that was adulterated with picric acid.

* * *

The *Ceylon Observer* thinks it probable that before long a quinine manufactory will be established in the isle of Ceylon, in the neighbourhood of Nuwara Eliya, where the occurrence of available water-power and an abundant supply of bark are considered to be favourable to the success of the enterprise. It appears to us, however, that the problem of cultivating the cinchona tree to the greatest advantage will be quite sufficient for the present to task the best energies of the island.

* * *

In a communication to *Nature*, Professor Cohn, of Breslau, calls attention to the fact that exactly two centuries have elapsed since Antony van Leeuwenhoek, writing from Delft in 1683, informed the Royal Society that with the aid of his microscope he had discovered "in the white substance adhering to his teeth very little animals moving in a very lively fashion." These were the first bacteria ever seen by the human eye; but so accurate were the drawings of them made by the Dutch observer that Professor Cohn says that they are easily recognized, and he mentions the species.

* * *

A curious incident in the history of an institution aspiring to be considered "national" is said to have happened at the "National College of Pharmacy, Washington, D.C.," from which forty-six students, headed by the president of the College Association, have withdrawn, as an expression of their displeasure at the admission of a coloured man into the school. In view of the strong objection of these gentlemen to "colour" the *Weekly Drug News* suggests that in the manufacture of bleaching powder, or the preparation of peroxide of hydrogen, they would be likely to find a field more congenial to their tastes than in pharmacy in the States.

* * *

According to the *Canadian Pharmaceutical Journal*, the Princess Louise, shortly before leaving Quebec, applied as an eye-lotion a preparation intended for another purpose, with a result sufficiently serious to prevent her from going to the Citizens' Ball.

* * *

A testimonial, consisting of an illuminated address and a purse of money, has been presented to Mr. Boverton Redwood, F.C.S., F.I.C., by members of the petroleum trade in London and the Provinces, in recognition of his services in connection with the inquiry, before a Select Committee of the House of Lords, into the late Petroleum Bill.

* * *

The usual Christmas lectures at the Royal Institution, adapted to a juvenile auditory, will be delivered this year by Professor Dewar, the subject being "Alchemy, in relation to Modern Science." The series will consist of six lectures, and the first will be delivered on Thursday, the 27th inst. The Friday evening discourses are to commence on January 18, with a lecture on "Rainbows," by Professor Tyndall; and among the other subjects announced as probable are, "The Darwinian Theory of Instinct," by Mr. G. J. Romanes; "The Chemical Work of Wohler," by Professor Thorp; "Theory of Magnetism," by Professor Hughes; and "The Two Manners of Motion of Water," by Professor O. Reynolds.

Transactions of the Pharmaceutical Society.

GENERAL MEETING—BENEVOLENT FUND.

ELECTION OF ANNUITANTS.

A General Meeting of the Members, Associates in Business, and Associates of the Pharmaceutical Society and of the Subscribers and Donors to the Benevolent Fund, was held at the house of the Society, 17, Bloomsbury Square, on Monday, December, 17, at 12 o'clock, for the election of Six Annuitants.

Mr. Michael Carteighe, President, in the chair.

The notice convening the meeting was read.

Scrutineers were appointed, who examined the voting papers and brought up the following report:—

Scrutineers' Report.

We, the undersigned Scrutineers, appointed at the nineteenth election of Annuitants on the Benevolent Fund of the Pharmaceutical Society of Great Britain, do hereby certify that we have examined the voting papers committed to us and report the following result:—

Barber, Joseph	5364
Wavell, John	4189
Barker, Caroline	2928
Powell, Mary Jane	2861
Taylor, Henry	2298
Tucker, Charles	2182
Cooke, John	2162
Fowler, Sarah Anne	944

3930* voting papers were received, of which number 71 were informal (46 unsigned) and were disallowed.

Geo. S. Taylor, *Chairman.*

Charles J. Mead. W. T. Frost.
Walter Hills. Robt. Rowe.
T. Howard Hall. J. O. Braithwaite.
Chas. E. Turner. Wm. H. Kerr.
Edward Henry Storey. Edwd. B. Stamp.
Jas. T. Tupholme. Sidney Constance.
Chas. B. Allen. R. S. Dampney.
Wm. I. Gulliver. R. Fisher Young.
E. N. Butt.

December 17, 1883.

The President declared the following six duly elected Annuitants:—

Barber, Joseph.
Barker, Caroline.
Powell, Mary Jane.
Taylor, Henry.
Tucker, Charles.
Wavell, John.

A vote of thanks was given to the Scrutineers for their long and arduous duties.

* 5856 voting papers issued.

EXAMINATIONS IN LONDON.

December, 1883.

Present on each day—Mr. Carteighe, President; Mr. Atkins, Vice-President; Messrs. Barnes, Benger, Brady, Corder, Ekin, Fletcher, Gale, Greenish, Linford, Plowman, Southall, Tanner, Taylor and Thresh.

Dr. Greenhow was present on the 12th and 19th, on behalf of the Privy Council.

MAJOR EXAMINATION.

12*th.*—*Six* candidates were examined. *Two* failed. The undermentioned *four* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Bing, Charles..........Canterbury.
Burford, Samuel Francis..........Leicester.
Dymond, Thomas Southall..........Bristol.
Low, David..........Hexham.

13*th.*—*Seven* candidates were examined. *Three* failed. The undermentioned *four* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Collins, Herbert Sleight..........Bradford.
Cornwell, Thomas Chinsura..........Penzance.
Dolbear, John..........Torquay.
Jones, Charles..........Ashton-under-Lyne.

19*th.*—*Six* candidates were examined. *Two* failed. The undermentioned *four* passed, and were declared qualified to be registered as Pharmaceutical Chemists:—

Mitten, Flora..........Hurstpierpoint.
Mowatt, John Rodman..........London.
Sergent, William Thomas..........Croydon.
Taylor, Ernest Sanderson..........Grantham.

MINOR EXAMINATION.

12*th.*—*Twenty-one* candidates were examined. *Sixteen* failed. The undermentioned *five* passed, and were declared qualified to be registered as Chemists and Druggists:—

Bradford, George Henry..........Bradford.
Brown, Edgar Marshall..........Derby.
Butterfield, Joseph William..........Blackburn.
Dorning, Herbert Rigby..........Chorley.
Dutton, William..........Sheffield.

13*th.*—*Twenty-three* candidates were examined. *Eighteen* failed. The undermentioned *five* passed, and were declared qualified to be registered as Chemists and Druggists:—

Brown, Horace..........Thrapston.
Burgess, William..........Runcorn.
Foster, William..........Dewsbury.
Heaver, Arthur William..........Norwich.
Taylor, Edward..........Tonbridge.

19*th.*—*Twenty-two* candidates were examined. *Sixteen* failed. The undermentioned *six* passed, and were declared qualified to be registered as Chemists and Druggists:—

Brown, Richard..........Rochester.
Jackson, Walter..........Catterick.
Millhouse, Edward..........Grantham.
Peck, Edward..........Ely.
Smith, Albert Edward..........Sudbury.
Williams, Frederick..........Bath.

20*th.*—*Twenty-seven* candidates were examined. *Thirteen* failed. The undermentioned *fourteen* passed, and were declared qualified to be registered as Chemists and Druggists:—

Jackson, John Thomas..........Scotforth.
Playford, Robert Henry..........Horsham.
Pomeroy, Francis Thomas..........South Petherton.
Ray, Charles..........Eastbourne.
Richardson, John..........Mansfield.
Roberts, Rowland..........Holyhead.
Shacklock, James Henry..........South Cave.

Shannon, Robert James ....Birmingham.
Tallantyre, John M. ....Manchester.
Thornton, Leonard Booker......London.
Turner, Aubrey ....Derby.
Wilkinson, Robert ....Kirkham.
Wood, John ....Leighton Buzzard.
Wride, Francis Blake .... Shirley.

MODIFIED EXAMINATION.

12*th*.—*Two* candidates were examined. *One* failed. The undermentioned passed, and was declared qualified to be registered as a Chemist and Druggist:—

Price, Benjamin William ......Farnham.

PRELIMINARY EXAMINATION.

The undermentioned certificates were received in lieu of the Society's examination:—

Certificates of the College of Preceptors.

Hughes, John Lloyd ....Wrexham.
Qualtrough, Thomas S. ....Douglas.

Certificate of the Society of Apothecaries of London.

Croxford, William Charles ......Brentford.

Certificates of the University of Cambridge.

Asbury, Thomas ....Buxton.
Chamberlain, Edward Tracy ...Hull.
Foot, Frederick John ....St. Mary Church.
Holden, George Henry ....Walsall.
Wall, Augustine William ......Highgate.

Certificates of the University of Oxford.

Balmford, John Archibald......Huddersfield.
Chard, John Aloysius ....Fairford.
Pater, Edward Rhodes............Newark.
Richards, Thomas Coombs......London.

Provincial Transactions.

MIDLAND COUNTIES CHEMISTS' ASSOCIATION.

The second meeting of the session was held at 23, Burlington Chambers, New Street, Birmingham, on the 13th instant, Mr. Joseph Lucas, President, in the chair.

A lecture was delivered by Mr. David Hooper, F.C.S., on "Justus von Liebig : His Life and Works." A sketch was first given of Liebig's life, from the time when as a druggist's apprentice he manifested propensities for experimenting, to his appointment as Professor of Chemistry at Giessen University. Liebig's works in organic, agricultural, and physiological chemistry were reviewed, his theories in the former science being illustrated by a series of diagrams. The lecturer then gave some interesting account of Liebig's views with regard to the chemistry of cooking, and referred to some of his discoveries in this department of applied science. The lecturer said that chemists and druggists are much indebted to Liebig for his ingenuity in working in drugs and testing medicinal chemicals. He investigated kinic acid, which is naturally associated with the alkaloids of cinchona bark ; he examined the properties of amorphous quinine, and originated the ether test for the purity of quiniæ sulphas in the Pharmacopœia, which was afterwards modified by Stoddart of Bristol. He discovered the volumetric method for estimating hydrocyanic acid by means of nitrate of silver. He produced aldehyd and also chloral long before Liebreich discovered its medicinal properties ; and among many substances chemists and druggists are continually handling in their shops and laboratories, Liebig's name is connected with investigations of malic, lactic, hippuric, benzoic, formic, tannic, gallic, and fulminic acids. After mentioning the chief traits in Liebig's character, a high tribute was paid to him for his indomitable perseverance in working out details, and the method and order he practised in all his researches.

The lecture was illustrated by several experiments, apparatus, and diagrams, and was listened to by a large and appreciative audience.

At its close, the President proposed a hearty vote of thanks to Mr. Hooper for his interesting lecture, which was seconded by Mr. Robinson and supported by Messrs. Austin and the Honorary Secretary, who reminded the large number of assistants and apprentices present that it was still the intention of the Association to form classes for the pharmaceutical examinations if a sufficient number gave in their names.

MANCHESTER PHARMACEUTICAL ASSOCIATION.

The first meeting of the session was held in the Medical Theatre of the Owens College, on Monday evening, December 10, at 7.30 p.m.; Mr. G. S. Woolley, Treasurer, in the chair.

The Chairman, addressing the meeting, which was well attended, first desired Dr. Leech (Professor of Materia Medica in the Victoria University) to convey the thanks of the Association to the Council of Owens College for allowing the first sessional meeting to be held where they were assembled. He then dwelt upon the necessity of apprentices and students commencing their studies early in their career during their apprenticeship. By so doing they would be not only making the best use of their time but laying a good foundation of the knowledge on which their success as pharmacists in after life so greatly depended. He also advised young men to endeavour to pass in due course the Major examination, drawing their attention to the fact that almost without exception the most famous and successful pharmacists of the present day were those who in the early days of the Society passed their Major examination. Finally, he congratulated the authorities at Owens College on the election of Mr. W. Elborne to the post of Assistant-Lecturer in Materia Medica and Pharmacy, and called on Dr. Leech to say a few words respecting the College course of instruction for pharmaceutical students, recently established there.

Dr. Leech welcomed the pharmaceutical associates to the College, and expressed the hope that the arrangements made by the Council for the education of students in pharmacy would be found to meet all their requirements. He pointed out the advantages which would ensue if those entering on their career as pharmacists went through a regular course of collegiate education in the subjects of their calling instead of delaying the acquirement of a proper knowledge of these subjects till a short time before the final examination and then cramming up in as short a time as possible just as much information would enable them to pass it. According to the regulations of the department students would be required to attend in the first place courses of instruction in chemistry and botany, unless indeed they had already obtained a sufficient knowledge of these subjects. The education in botany and chemistry would be chiefly practical, and carried on in the laboratories. It might seem to some that the time spent in the microscopic examination of vegetable tissues, in the dissection of flowers, or in chemical analysis was thrown away; but this was not so. Such practical knowledge of a science, it had been found, should always precede the technical instruction in those subjects requiring a knowledge of the science, and the education of pharmacists on the lines laid down by the Council of the College would give pharmacy a higher status and prove advantageous to the public and especially so to medical men. Dr. Leech pointed out that to meet the varied requirements of students as regards times of attendance classes were being organized both in the daytime and in the evening. He also drew attention to the fact that students in pharmacy would receive tickets giving them free admission into the Botanical Gardens for the purpose of studying the medicine-yielding plants, of which a collection is now being formed.

The Chairman then called upon Mr. Elborne to give an address on "The Examinations of the Pharmaceutical Society."

The Examinations of the Pharmaceutical Society.

BY WILLIAM ELBORNE,

Assistant Lecturer in Materia Medica and Pharmacy, and Curator of Materia Medica Museum, Owens College.

The lecturer commenced by saying that at no period in the history of pharmacy had educational progress been more rapid than it is at the present day. The influence to which this onward movement is due might be attributed to the activity of individual members of the pharmaceutical body who take an interest in their calling, and to the zeal of those unaggressive workers to be found in the laboratory. From the fact of laboratory work having accomplished so much in the advancement of pharmaceutical science, it had assumed such importance in schemes of instruction and examinations that pharmaceutical education without it was a nonentity. This having become generally acknowledged throughout the community, the Council of the Pharmaceutical Society had become desirous of enforcing a better system of education, in the form of a compulsory curriculum. He proposed to offer a few remarks respecting the various examinations of the Pharmaceutical Society, treating them in such a manner that they might prove of service to students generally. The term "pharmaceutical student" was defined as indicating one who, having passed his Preliminary examination, follows pharmacy as his calling and endeavours to progress in the knowledge of its subjects. As well known, the junior members divided themselves educationally into two groups, viz., Minor students and Major. The greater portions of the course of study for the Minor should be extended over the student's apprenticeship, that period forming a most important epoch in the student's history; a time which it entirely rested with himself to either make the best use of or to throw away. In many instances young men who entered the trade and became bound to learn the art and mystery of a chemist and druggist did so with but vague ideas of the brain-work which lay before them, and, as a rule, it was not until after the lapse of years that they began to realize the true nature of the examinations in store for them. Mr. Elborne said the first thing he would recommend an apprentice to do would be to purchase and study the current 'Calendar of the Pharmaceutical Society of Great Britain.' There only would he be able to obtain that information which immediately concerned his future welfare and progress and be enabled to plan out for himself a proper course of study. The intelligent apprentice would also soon discover that the governing body which one day would examine him offers many encouragements to persevering students, in the shape of scholarships, medals and prizes. All students, therefore, who were interested in their own welfare, would, in his opinion, do well to join the Society as early as possible in their career. The privileges accruing in so doing were many. In the first place the student would associate himself with the respected and learned community which governed and protected his interests and calling; he would receive the weekly journal containing the report of the Society's transactions—the recognized organ of the trade; and further, he would have at his service its editorial department, which to inquiring students was of inestimable value. Secondly, he would have the use of the Library and Museum, comprising the finest collection of pharmaceutical literature and materia medica specimens in the world; he would be also presented with a comprehensive catalogue of each. Thirdly, he would be invited to compete for the Bell scholarships, Herbarium and Council prizes. Those who had more recently left school or had kept bright their knowledge of Latin, French or German, he earnestly recommended to try for the Bell scholarships, which were open for competition to all the Society's students under twenty-two years of age; there was, consequently, a good margin of time for preparation. Not only did successful competitors receive each £30 cash, but a free education into the bargain, whilst a "Bell scholar" held in the eyes of pharmacists a respected position, and his tenure of the scholarship brought him into immediate contact with a staff of distinguished professors and persons ever ready to help him on further in his studies and upward progress. In reference to the Herbarium prize, the competitor, to start with, must, he thought, live in the country and have a natural love for plants and field botany, and also plenty of time at his disposal for collecting, mounting, etc. The collection of a good herbarium required an enormous amount of labour, and those who undertook such were certainly to be commended for their pains. Those who lived in the neighbourhood of any botanical gardens should, however, be sure and pay a visit—say monthly, in order that they might become practically acquainted with all the official medicinal plants indigenous to this country (about fifty), which were generally to be found there among the economic beds. With respect to the Minor or qualifying examination, he said that the subjects of this examination were numerous, including chemistry, pharmacy, botany, materia medica, prescription reading and dispensing. The intelligent student would soon find that he is unable to understand pharmacy properly without possessing a knowledge of chemistry, materia medica without the knowledge of botany, nor dispensing without understanding prescriptions. The preparation for the Minor must, therefore, be built, as it were, upon three large pharmaceutical bricks,—knowledge of chemistry, botany and the language of prescriptions,—a foundation which should be laid as early as possible during apprenticeship. The first theoretical subjects, therefore, to which students should devote their hours of study were chemistry and botany, either by attending any such evening classes as are available in their surroundings, or by home study. He would also impress upon them the necessity of keeping their eyes open during the daily routine behind the counter, observing the characteristic appearance of every drug and chemical which came under their notice and recognizing all the various spirits, tinctures, extracts, pills, and compound powders by cautious taste and smell. By doing this they would be largely cultivating their observing faculties, besides learning a great deal which they would be able to turn to good account in the examination room. Having gained the theoretical knowledge of chemistry, elementary physics and botany, they could then be entitled to open the British Pharmacopœia, the book which must be so elaborated as to form an epitome of all their studies. It was most essential that every student should possess a copy of his own at an early date, and immediately make up his mind to esteem it as a text-book and note-book as well, using the margin for the entry of full notes upon the various drugs and preparations. A good book on materia medica should be treated in a similar manner, by filling in the margins with the natural order of the drug, percentage of active ingredient, brief mode of collection, its adulterations, impurities and substitutions. By so doing they would be turning the numerous blank spaces and wide margins to good account, and the book itself would no longer appear a dreary waste, but become a most valuable text-book and self-constructed record. At the same time students were recommended not to forget their practical pharmacy and technical work in the shop, cultivating good habits and picking up all the practical information they could in dispensing and tabulating it. The author then brought this part of the paper to a close with some hints with respect to preparation for an appearance in the examination room. Turning to the subject of the Major examination, he said it should, of course, be taken into consideration immediately after having passed the Minor, when the student would be in the best position to further brighten up his scientific subjects and devote his whole time to work, which after having got through the drudgery would become a pleasure. Then a man who had passed the Major should not forget the Pereira and Council prizes. The Pereira Medal was considered the blue ribbon of pharmacy and was open to all those connected with the Society that had passed their Major during the same pharmaceutical year.

After Mr. Elborne's address, a discussion took place in which the Chairman, Dr. Leech and Mr. Robinson, of Pendleton, took part.

Mr. Elborne having replied, the Chairman proposed a hearty vote of thanks, which was seconded by Mr. Botham and carried unanimously.

The Chairman then called upon Mr. Elborne to make a few remarks respecting the collection of Indian cinchona barks, exhibited upon the table, which had been presented to the Association by the Pharmaceutical Society.

Mr. Elborne stated that the subject of cinchona barks was a very vast one, especially as regards the supply which came to England from the British Colonies and India. He said it was a subject to which he had devoted considerable attention, and for a brief history of its modern features, he thought he could not do better than refer those interested in the subject to one of his recent papers published in the *Pharmaceutical Journal*, entitled "A Summary of the Cinchona Barks of Commerce." He said that the barks upon the table were from the plantations of Darjeeling, and that at some future meeting he hoped to be able to give them a paper on the subject.

At this stage of the proceedings, the Chairman invited the meeting to accompany Mr. Elborne and proceed to make an inspection of the new buildings (as announced). Having assembled in the Materia Medica Museum, Mr. Elborne stated that the pharmaceutical buildings comprised the Museum they now had the pleasure of inspecting, a Pharmaceutical Laboratory and a Professor's Laboratory, specially set aside for pharmacological work. In reference to the Museum, he said that as regarded its dimensions and bench accommodation for students, it was, he thought, unequalled by any in the kingdom, inasmuch as no less than twenty men could be comfortably seated at the same time while studying the accessible specimens. The students' bench was also admirably lighted and furnished with a microscope. The leading feature of the Pharmaceutical Laboratory, he said, was the fine dispensing counter it contained, which was fitted up with every requisite, including gas and water, and would enable twenty men to be dispensing at the same time. There were also private benches in the Professor's Laboratory, intended to be used by gentlemen desirous of undertaking any original investigation or research.

The meeting then terminated.

HANLEY PHARMACEUTICAL STUDENTS' ASSOCIATION.

A meeting was held at the residence of Mr. Moore, 7, Market Square, Hanley, on Thursday, December 6, at 6 p.m., to consider the advisability of forming a Students' Association for the chemists' assistants and apprentices in the town. There were present—Messrs. J. W. Moore, E. Jones, and J. F. Eardley, principals, and five apprentices.

Mr. Jones having taken the chair, Mr. Moore opened the meeting by explaining the cause for and advantages to be gained by the assistants and apprentices forming themselves into an Association for study and general advancement.

It was then unanimously agreed to form an Association, and that the name of the Association should be "The Hanley Pharmaceutical Students' Association." It was also arranged that the night for meeting should be Tuesday, from 8.30 to 10, and that there should be only two classes formed this session, "Preliminary" and "Chemistry." Mr. Moore was requested to see a gentleman in reference to the formation of the Preliminary class, and Mr. Eardley assented to an unanimous request to conduct the Chemistry class for the first session.

It was agreed that the first meeting of the Association be held on Tuesday evening, the December 11, at 8.30. Mr. Moore kindly offered to provide a room for meeting *pro tem.*, which was accepted.

Votes of thanks were passed to the Chairman for presiding and to Mr. Moore for bringing the matter forward and his efforts to establish the Association.

The first meeting of the Association was held on Tuesday, December 11. The Chemistry class was commenced, eight students entering their names. Should the Association prove a success, it is intended next session to invite the co-operation of the assistants and apprentices of the neighbouring towns.

Proceedings of Scientific Societies.

SOCIETY OF ARTS.

The Scientific Basis of Cookery.

At the commencement of the last of the series of Cantor lectures, on the "Scientific Basis of Cookery," by Mr. Mattieu Williams, the lecturer again explained the relations existing between the processes of boiling and stewing. He then proceeded to the subject of maceration, by which process, he said, the juices and non-colloid constituents of the food could be extracted unaltered through the agency of exmosis, the viand being cut in small pieces and steeped in cold water, without application of heat. The colloid constituents, consisting of the non-crystallizable substances, were thus separated from the more nutritious parts, which, being soluble, were readily taken up by the system of an invalid, without undergoing the process of digestion in the stomach. In this way beef-tea could be prepared for an invalid whose stomach is not equal to the task of digesting gelatin; this food would not, however, satisfy the invalid when he became stronger, as he would require something more sustaining. Mr. Williams then introduced the subject of casein, as the most important part of the evening's discourse. He remarked that casein could be separated even from skim milk by means of rennet or an acid, and unlike albumen it is not affected by heat, boiled milk being equal in value to fresh in the manufacture of cheese. Casein occurs in two forms, in the soluble form in milk, in the insoluble form in cheese. Several materials are in use for the separation of the casein. Rennet acts by decomposing the milk, lactic acid, which is the real separating agent, being formed; hydrochloric acid is also largely used for this purpose. The lecturer said that the cost of cheese is very low compared with that of beef, as although nearly the same price per lb., yet 1 lb. of lean beef contained 72 per cent of water, whilst cheese only contained 30 per cent, so that 20 lbs. of cheese was nearly equivalent in food material to 60 lbs. of beef. He also noticed the great superiority of cheese over meat in point of portability, as cheese might be imported from foreign countries without any trouble and could indeed be used as ballast. Pure casein has no taste or smell, and if carefully prepared, by neutralizing with an alkali, can be obtained in a soluble form. Mr. Williams considers cheese should never be eaten by anyone in the indigestible form in which it is sold, and that it is always hard to digest if not properly cooked. To make cheese digestible, he said, it is necessary to re-convert it into the soluble form as when in milk; he had found it preferable to heat it with milk or water containing a little bicarbonate of potash so as to neutralize the acid that had caused its separation. Or it could be used, as in Italy for the flavouring of soups. The lecturer mentioned several recipes for preparing dishes from cheese, among which was one consisting of ¼ lb. of cheese, water, a little bicarbonate of potash, and three eggs, which he said was very good when cooked. He further drew attention to the fact that, upon analysis, the same results are given by Parmesan cheese and cheese made from skim milk, which latter, commonly known as "Cream Dick," is considered only fit for farm labourers. Mr. Williams then passed on to speak of "bosch" or "butterine," which, he said, although better than many butters, simply consisted of scientifically prepared dripping. He next pointed out the importance of vegetables considered as articles of food, remarking that the elements of vegetables and meat were the same, and that they contained equivalent constituents. He also mentioned the value of ensilage as applied to vegetable food, as by this means the tough woody parts were converted into dextrine. For instance, whole meal bread would be much more nutritious if the bran were rendered more digestible by ensilage; again, Jersey pears, although hard and woody when plucked from the tree in September, became sweet and juicy if kept till December. This fact also might give a meaning to the old adage, "Pease pudding hot, pease pudding cold, pease pudding in the pot nine days old." Mr. Williams, in conclusion, remarked that the time might come when "scientific cookery" would enable man to dispense with animal food, and that then food supplies would be more easily obtainable from all parts of the organic kingdom.

Obituary.

Notice has been received of the death of the following:—

On the 20th of October, Mr. William Pissey, Pharmaceutical Chemist, Rayleigh, Essex. Aged 65 years. Mr. Pissey had been a Member of the Pharmaceutical Society since 1853.

On the 24th of October, Mr. John Abel, Chemist and Druggist, Forfar. Aged 47 years.

On the 28th of October, Mr. John Tankard, Chemist and Druggist, Manchester Road, Bradford. Aged 39 years.

On the 30th of October, Mr. Henry Milner Hughes, Chemist and Druggist, Overton, Ruabon. Aged 27 years.

On the 2nd of November, Mr. Isaac Jack Reeve, Chemist and Druggist, High Street, Newhaven. Aged 60 years.

On the 4th of November, Mr. Henry Robert Kemp, Chemist and Druggist, Holloway Road, N. Aged 49 years.

On the 5th of November, Mr. Henry Maiden, Chemist and Druggist, Haymarket Street, Bury. Aged 66 years.

On the 8th of November, Mr. Cristopher Innes Macarthy, Chemist and Druggist, Romford. Aged 50 years.

On the 9th of November, Mr. Henry Dickerson, Fore Street, Devonport. Aged 78 years. Mr. Dickerson was a Pharmaceutical Chemist Member of the Society from 1842 to 1881.

On the 13th of November, Mr. William Bankes Hudson, Pharmaceutical Chemist, Haymarket, W. Aged 71 years. Mr. Hudson was one of the Founders of the Pharmaceutical Society, having joined it in 1841.

On the 17th of November, Mr. William Smith, Pharmaceutical Chemist, Sutton Coldfield. Aged 77 years. Mr. Smith had been a Member of the Pharmaceutical Society since 1842.

On the 18th of November, Mr. Joseph Revill Pennington, Chemist and Druggist, Calton Road, Worksop. Aged 44 years.

On the 26th of November, Mr. Isaac Garrett, Chemist and Druggist, Queen's Road, Brighton. Aged 53 years.

On the 27th of November, Mr. Charles Elkington, Chemist and Druggist, Rugby. Aged 64 years.

On the 8th of December, Mr. James Laws, Chemist and Druggist, Mare Street, Hackney. Aged 57 years.

On the 14th of December, Mr. William Kimberley, Chemist and Druggist, Balsall Street, Birmingham. Aged 77 years.

On the 14th of December, Mr. Alexander Grant, Chemist and Druggist, Cullen, N.B. Aged 26 years.

Reviews.

THE INTERMEDIATE TEXT-BOOK OF PHYSICAL SCIENCE.* By F. H. BOWMAN, D.Sc., F.R.A.S., F.L.S., etc.

The key-note of much of modern research in science and more especially in physical science is struck when it is said that the ordinary man of science is broadly a worker and not a thinker in the special branch to which he belongs. The truth of this and its lamentable results are acknowledged on all hands by men of science, and have attracted much attention and comment from the outside world. It is painfully prominent in the science of chemistry, where every day adds a new name to the already enormous mass of unutilized and unclassified facts the bearing of which one to another and to the general principles of the science is left undetermined; their very discoverers apparently shrinking from the mental task of generalization and caring little for the logical consistency of the science and its doctrines when viewed as a whole. Professor Huxley is one among the very few men who are able to take that wide and philosophic view of science as a whole, and who have endeavoured to give a precise and consistent account of the objects and bearings of physical science. This was done, and as far as it went was very admirably done, by Professor Huxley in his "Introduction" to the series of 'Science Primers.' There was, however, needed, and there still is needed, a book written in the same precise, yet simple way, but ranging over a much more extended field; in point of fact, Professor Huxley himself suggested the existence of such a book which could profitably be used where a general, more than a special, knowledge of physical science and its principal discoveries is required, a book which should open with a clear, consistent and intelligible exposition of the aims and instruments of scientific thought and then proceed to a general untechnical and systematic statement of the principles and leading facts of each and all of the physical sciences, accompanied by such reference to experiment as is necessary for their full understanding. This extremely difficult task has been attempted by Dr. Bowman in the book before us, he having, as we are informed in the preface, followed out the suggestion of Professor Huxley. It is evident that the author has a wide general knowledge of physical science, but what is wanted for the full consummation of such a task as this is not only quantity of knowledge but quality of mind. Whatever Dr. Bowman may be as a scientific worker he is certainly in no sense of the word a scientific thinker; his thought and utterance as portrayed in many parts of this book are destitute of those very qualities which are designated scientific. More profound intellectual confusion is not to be met with than that contained in the portion of the present work which deals with the meaning and methods of physical science, and indeed, wherever the author leaves the ground of empirical description of scientific facts. To have read both Whewell's 'History of the Inductive Sciences' and Jevons's 'Principles of Science,' which roughly represent ancient and modern scientific thought, without having previously fully and systematically considered the problems there treated, can only lead to the most utter and complete confusion. Indeed, this section of

* London: Cassell, Petter, Galpin and Co. Extra fcap. 8vo. Pps. i-xvi., 1-320.

the book is a strange mixture of the opposing statements of Whewell and Jevons without any attempt at reconciliation, and forms such a tangle and jungle of inaccuracies as is seldom to be met with. This is a severe expression, yet it is the only expression which adequately and fitly characterizes the introduction to Dr. Bowman's attempt "to enlarge the range of the intellect and open up a wide field of pleasure which might otherwise be closed." A few striking passages shall be quoted to justify the above criticism, although the majority of the introduction might be cited in its support. Here, for instance, are examples where inaccuracy, looseness and contradiction are fused in the definition of two of the most important words employed in physical science—law and induction. On page 2 we are told that "*the cause* which underlies the changes which are produced by the action of force upon matter is called a *physical cause*; and the constant relationship which obtains or subsists between a physical phenomenon and its cause is called a *physical law*." Here, be it observed, is defined the difference between a physical cause and a physical law, but on page 30 this difference becomes an identity. "Induction may be said to be the method of investigation which seeks to determine *the causes which lie underneath the phenomena and which we term laws*; just as deduction is the process by which the law inductively discovered is traced in new instances." And with true consistency this definition of induction is contradicted upon page 12 by the statement that we "deduce the laws which underlie the phenomena." This kind of confusion is the result of a pernicious and unscientific use of the word law in two senses. However this is not the place to rectify Dr. Bowman's errors, but only to point them out, and deplore their existence. Unfortunately, equal looseness of thought and expression is not restricted to this portion of the book; it also pervades that part which deals with more strictly technical subjects. It is displayed to perfection in the chapter upon "Statical Physics" (p. 33), where the author endeavours to explain the meaning of "Weight." "So far as any given quantity of matter is concerned its *absolute weight will remain the same whenever and wherever it is*, considered in regard to the same quantity of matter, either of its own or any other kind, and we measure this weight numerically by the intensity of the resultant of the earth's attraction upon the molecules of the body." In the next paragraph we meet this eminently clarifying rider:—"Measured, however, by this standard, the numerical *absolute weight* of a body *does not remain constant* in all parts of the universe or indeed of the earth's surface." Finally, to heighten the effect the section closes thus:—"Two pound weights which balance each other will do the same either in London or Glasgow or any part of the earth, or indeed of the universe, although their *absolute weights* as determined by the power which they possess to compress or extend a spring *will vary* in every position in which they may be placed." We pity the sentient being who gets his notion of "absolute weight" from these passages, and who probably concludes that one of the principal functions of physical science is to fog the mind of man. One more quotation in support of our dictum upon the merits or rather demerits of this book and we have done. On page 41, before any definition of a molecule or atom has been given, the following statement about cohesion occurs:—"It is distinguished from chemical attraction, which unites the atoms of different kinds of matter so as to form new substances, by the fact that it unites the molecules of the same kind of matter alone, and in the same way it differs from adhesion which unites the molecules of different kinds of matter." Under the head of "Chemistry," upon page 281, another statement about adhesion will be found which is in direct conflict with the present one. "Chemical union is most like cohesion or adhesion, but it differs from these in that while they occur most powerfully between matter of the same kind, chemical union is always the most powerful and energetic when the substances entering into combination exhibit the greatest differences in their kind."

When we saw the announcement of this book we thought and hoped that it would be precisely the book to suit the requirements of the pharmaceutical student, who under the present system is required to to have a sound general knowledge of physics, but we have been grievously disappointed, and our present advice to the pharmaceutical student is that the less that he has to do with the book the better will it be for him and his enlightenment. Just as the essence of scientific thought is found in its precision, so the essence of scientific expression is centred in its accuracy. The passages we have quoted suffice to show that it is in these very respects that the exposition contained in this book is wanting. The depressing task of reading the volume being over it was indeed a relief to quit this turbid atmosphere to enjoy the bracing air and exhilarating climate of the 'Introductory Science Primer,' and refresh oneself with Professor Huxley's precise knowledge, accurate language and lucid exposition.

PHARMAKOGNOSIE DES PFLANZENREICHES.* By F. A. FLÜCKIGER. Second Edition. Part III.

This is the concluding part of a work which promises to be to the German student in pharmacology what the 'Pharmacographia' is to the English student. As mentioned on a previous occasion (*Pharm., Journ.*, [3], xiii., 319), it includes most of the information contained in the *magnum opus* of the author and the late Daniel Hanbury, supplemented by fresh matter in relation to a few drugs that are relatively of more importance in Germany than in this country. For instance the present part commences with "Herba Jaceæ" (*Viola tricolor*), "Folia Malvæ," and "Folia Farfaræ." "Folia Theæ," which comes next, can hardly be said to be more in use on the Continent, but it forms a convenient heading under which to refer to other theine-containing plants.

The present part reveals the completion of the arrangement of the work. We must refer to the previous notice for a summary of the scheme so far as it was developed in the first two parts, and will only here briefly outline the remainder. It consists mainly of the third, fourth and fifth subsections of the section including the parts growing above the soil of the important sub-class of non-pulverulent organized substances. The third subsection is entitled "leaf-organs," and this is divided into (*a*) "bulbs"; (*b*) "leaves and (partly flowering) herbs," including (1) leaves with little taste or smell, (2) leaves with predominating astringent taste, (3) bitter leaves and herbs, (4) leaves and herbs of saline-bitter, acrid or pungent taste, (5) aromatic herbs and leaves; and (*c*) flowers, inflorescence and parts of flowers, including, (1) parts of flowers and (2) entire flowers and inflorescence. Subsection four is devoted to fruits, and is divided into (1) fruit rinds and fruit pulp; and (2) fruits, including (*a*) those having an oily or sweet taste, (*b*) those having a bitter taste, (*c*) those having a pungent taste, and (*d*) fruits in which an aromatic property preponderates. The last subsection consists of seeds and parts of seeds, including (1) seeds without bitter taste, oleaginous or mucilaginous, (2) bitter seeds, (3) seeds having a pungent or aromatic taste, and (5) seed appendages. This scheme of classification is really a somewhat further elaboration of that adopted by the author in the first edition of this work, but not followed in his joint work with Hanbury. We doubt whether the plan will find frequent imitation, but it certainly has the advantage of bringing many of the articles of the materia medica into a juxtaposition unusual in other manuals and so presenting them to the student under new aspects. But for those who prefer the botanical classification a table is provided which will enable them to see

* Berlin: R. Gaertner. Royal 8vo. Pp. i.-xvi.; 601-1049.

at a glance the pages upon which the substances derived from any particular order are referred to; while others who favour the less scientific alphabetical arrangement have a good index to which they can turn.

It is almost needless to state that the work is brought up to date, some of the most recent researches being referred to in the text.

Sophistication of Oil of Turpentine.

Sir,—In an editorial note in the *Pharmaceutical Journal* of December 15, you call attention to the sophistication of oil of turpentine with "petroleum benzine" reported by Her Majesty's Consul at Charleston.

Allow me to state that the presence in oil of turpentine of the more volatile hydrocarbons distilled from petroleum is very readily, simply and certainly detected by the application of the flashing test prescribed by the Petroleum Act, 1879.

The possibility of thus advantageously employing the apparatus devised by Sir Frederick Abel was casually suggested to me, in conversation, by Surgeon-Major Lyon, Government Analyst at Bombay, and I now habitually determine the flashing points of samples of oil of turpentine submitted to me for examination.

On another occasion I may ask you to publish some particulars of the range of flashing point of American oil of turpentiee, as imported, and the effect upon the flashing point of admixtures of substances likely to be used for sophistication.

In the meantime, I may mention that the addition to oil of turpentine of only 1 per cent. of ordinary petroleum spirit lowers the flashing poiut about 10° Fahr.

Those who do not possess the legal apparatus may, with care, obtain fairly comparative results with a beaker, one-third filled, over a water-bath.

Boverton Redwood, F.I.C., F.C.S.

85, *Gracechurch Street, London.*

The Partick Poisoning Case.

Sir,—As your paragraph in Saturday's issue under the above heading may create an unfavourable impression against our client, Mr. R. C. Rait, we think it right to state and explain, that while the civil responsibility to the public rested with him by "aconite" instead of "actæa racemosa" being dispensed, yet neither he nor any of his assistants was in any way the cause of the mistake, nor can any blame whatever be imputed to them. The Procurator Fiscal, in the criminal proceedings against one of the assistants, after a thorough investigaiion and analysis of the different medicines, abandoned the charge, and in the civil action, Mr. Rait explained in his defence that the "aconite" given to Mackay, was received from a firm of wholesale druggists in Glasgow, instead of "actæa racemosa," the medicine actually ordered.

Further, that while our client paid to Mr. William Mackay, the sum of £200 and expenses, by an agreement come to out of court, the wholesale druggists repaid Mr. Rait all this outlay and a considerable sum in addition to meet other expenses.

McLelland Thomson and Towers-Clarke,

Glasgow. *Law Agents for Mr. Rait.*

Red Cap.—It has been reported that the administration of hydrochlorate of pilocarpine has been followed by darkening of the hair (see *Pharm. Journ.*, [3], xii., 438), but we cannot say that we are aware that any "preparation of pilocarpine is used for dyeing the hair black, by means of internal application."

Créon.—Very different preparations are sold under the name of "lime juice and glycerine" and several recipes have been already published in this Journal. The following is taken from Canning's 'Select Notes':—Lime juice, ½ pint; rose water, ¼ pint; sp. v. r., added gradually, 2 oz. Shake well, after twenty-four hours strain through muslin, and add ol. limonis, ½ drm., ol. lavand., 15 drops, dissolved in s. v. r., 4 drs. Lastly add glycerine, 2½ fluid ozs. and shake well.

Registered is recommended to address his question to the Registrar under the Veterinary Surgeons Act.

Student.—We should think not, unless he has passed an equivalent to the Preliminary examination.

C. Potter.—The law makes no exception and the answer given last week applied strictly to both parts of your question. As to our *opinion* in respect to the probable application of the law, see *Pharm. Journ.* for June 9 last, p. 1025.

J. P., jun.—"Troch. Cubebæ, T. H."—Cubebs in powder, 200 grs.; extract of liquorice, 1225 grs.; tragacanth in powder, 70 grains; refined sugar, 200 grains; black currant paste, q. s. Mix the dry ingredients, then add the black currant paste until the whole mass weighs 1 lb., divide into 350 lozenges of 20 grains each and dry them in a hot-air chamber at a moderate heat.

Associate.—Lactic acid has been recommended as useful in the treatment of diabetes, one to three drachms being given daily; it has also been used as a remedy for dyspepsia. As a solvent of the diphtheritic membrane solutions have been recommended varying from one of "acid" and five of water to one of "acid" and twenty of water, but no indication of the strength of the acid itself is given. The U.S.P. sp. gr. is 1·212, which is said to represent 75 per cent. of absolute lactic acid and 25 per cent. of water.

F. Wright.—Before we can deal with the matter referred to in your letter, in the manner you desire, we must be fully acquainted with the facts of the case.

J. H. Henry.—The subject of your letter is referred to on p. 493.

J. J. Macaulay.—The lesser galangal root (*Alpinia officinarum*).

T. F. Abraham.—We believe that the sunflower is cultivated in the south of Europe and in Russia for the sake of the oil that can be obtained from the seeds, but we are not aware that it is cultivated for that purpose in England. You will find some information on the subject in *Pharm. Journ.* [3], ii., 106, and vii., 117.

Botanist.—Bentley's Manual of Botany, published by J. and A. Churchill, price 15s., or the smaller work of the same author.

Pharmacopolist.—The 12th section of the Pharmacy Act, 1852, provides that "it shall not be lawful for any person, not being duly registered as a pharmaceutical chemist according to the provisions of this Act, to assume or use the title of pharmaceutical chemist or pharmaceutist in any part of Great Britain, or to assume, use, or exhibit any name, title or sign implying that he is registered under this Act."

"*Emigrant.*"—The colonial Act provides for the acceptance of evidence of the English qualification in lieu of an examination.

J. Wyatt.—Professor Flückiger was the first person to whom a Hanbury medal was awarded.

Communications, Letters, etc., have been received from Messrs. Samuel, Maben, Churchill, Apprentice, Novice, Natron, F. A.

"THE MONTH."

The relative activity of certain metals in the oxidation of oils, which was the subject of an interesting paper by M. Livache some months since (*Pharm. Journ.*, [3], xiii., 942), has been further investigated with results that promise to be of industrial importance (*Comptes Rendus*, xcvii., 1311). In imitating an industrial method of preparing drying oil, in which the oil is heated with minium or litharge, together with manganese generally used in the state of borate, M. Livache added to an oil which had been heated with lead obtained in a fine state of division by precipitation, as described in his previous paper, some finely pulverized sulphate of manganese, the result being the formation of an insoluble lead compound and a complete displacement of the lead by manganese. The oil produced was extremely siccative, drying when placed in a thin layer upon glass completely in five or six hours. Upon increasing the fluidity of such an oil by mixing it with equal parts of benzine and shaking it in a closed vessel, a rapid absorption of oxygen takes place, which is increased if the temperature be kept between 40° and 50° C., and if the air be renewed at intervals, so as to replace the oxygen absorbed, a point is reached at which after the separation of the solvent by distillation the oil upon cooling becomes a dry elastic homogeneous solid. This product is absolutely insoluble in water, alcohol or ether, but is nearly immediately saponified in the cold by potash.

The importance of the freedom of oils intended to be used as lubricants from uncombined fatty acid is well known, and M. Krechal proposes a test for this purity based upon the facts that acetate of rosaniline is not dissolved by neutral oils, but is dissolved by free fatty acids, and that rectified petroleum is a solvent of oils, but not of acetate of rosaniline, though it does not precipitate that compound from a solution in fatty acids (*Journ. Pharmacie*, [5], viii., 430). Ten c.c. of the oil are shaken in a test-tube with 1 c.c. of a strong alcoholic solution of acetate of rosaniline, and the test-tube is then placed in the water-bath for an hour to drive off the alcohol. Sufficient rectified petroleum is then added to increase the volume to 100 c.c., and of this 10 c.c. is taken, further diluted about ten times, and then titrated with petroleum containing sulphurous acid, prepared by digesting petroleum with about one-fourth of its volume of sulphuric acid and allowing it to become clear. The decolorizing effect of this upon acetate of rosaniline must be determined before each experiment.

Two kinds of yellow pigment are met with in India under the name of "piuri," or Indian yellow, one of mineral origin, imported from London, the other said to be of animal origin and manufactured at Monghyr, in Bengal. As some uncertainty existed respecting the correctness of this latter statement, inquiries have been made by the Indian Government, at the instance of Sir J. D. Hooker, by which it has been substantiated. The manufacture of animal "piuri" appears to be carried on in a suburb of Monghyr, on a very limited scale, by some members of the sect of gwalas (milkmen). The substance is the dried product of the evaporation of urine from cows that are fed exclusively upon mango leaves, which fodder is said to increase the bile pigment and impart to the urine a bright yellow colour. The cows are said to become very unhealthy under the treatment, and the owners are consequently compelled to give them occasionally grass and other kinds of fodder; but the change is always followed by a decrease in the yield of pigment, which is about two ounces daily. The animal piuri is of an exceedingly bright colour, and is therefore considered superior to the article of mineral origin.

A new compound of quinine with chloral is described by Dr. Mazzara (*L'Orosi*, vi., 430), which he believes will prove to be a type of a series of compounds of chloral with the alkaloids. It is prepared by adding to a solution of quinine in chloroform an equivalent quantity of chloral, and allowing the mixture to evaporate at the ordinary temperature. The gelatinous transparent yellowish residue is taken up with ether and the solution gently warmed, when an abundant separation of white warty crystals immediately commences, and in a short time the whole liquid is converted into a crystalline paste. Or the compound may be prepared directly by dissolving 32 parts of anhydrous quinine in chloroform, diluting this solution with anhydrous ether, adding 147·5 parts of chloral and gently warming. The crystals are washed with cold ether and dried over sulphuric acid, and are thus obtained snow-white, the crystals being tasteless at first with a slightly bitter aftertaste. The compound is represented by the formula $C_{20}H_{24}N_2O_2 \cdot CCl_3COH$. Chloral-quinine volatilizes unaltered in dry air at a temperature of 149° C. Its solutions in dilute acids are fluorescent and give the thalleioquin reaction. With sodium bicarbonate it gives a precipitate free from chlorine, and it is thought doubtful whether chloral-quinine can remain undecomposed in aqueous solution.

Some experiments made by Herr Lewkowitsch seem to show that it is possible to convert lævogyre-mandelic acid into the dextrogyre form, and *vice versâ*, passing through the intermediate optically inactive form. By heating the left-handed acid in a closed tube to 160° C. during thirty hours, a yellow crystalline mass was formed, smelling strongly of benzaldehyd, which was purified by treatment with water, and the clear solution was then optically inactive. After standing some days, crystals of paramandelic acid separated, from which dextromandelic acid was removed by combining it with cinchonine and decomposing the resulting salt. Still more interesting is the observation that when a certain species of *Schizomycetes* was cultivated in a solution containing inactive or paramandelic acid, it was found that after the growth was at an end and the liquid had had time to clear the liquid had become lævogyre, the fungus having apparently consumed all the dextro portion of the acid, and then ceased to develop.

In a letter to the *Chemical News* (December 2, p. 291), Mr. F. M. Lyte challenges the usually accepted explanation as to the combination of water of crystallization, the existence of hydrates and double salts and the combination of phosphorus pentachloride with iodine, bromine and iodine chloride, and other analogous combinations, which supposes that there exists either in the atoms themselves composing the molecule some residue of unsatisfied atomicity or that some of the atoms possess a variable atomicity. He asks whether there is any valid reason why it should not be supposed that the entire molecules, acting as entities or compound atoms, come to possess an atomicity of their own, attracting one another, or the molecules of water, as the case may be. At the first blush, it is not quite clear in what this atomicity of the molecule would differ from the sum of the residue of the unsatisfied atomicities spoken of; but Mr. Lyte does not think this a sufficient explanation of the energetic action which is manifested in some cases, resulting in a considerable development of heat, as when dry calcium or zinc chloride combines with water.

In 'Pharmacographia' it is mentioned that the slightly dextrogyre essential oil yielded by matico leaves (*Piper angustifolium*, R. et P.) deposit in winter long crystals of a camphor, having the odour and taste of the oil from which it is derived and melting at 103° C. A fine sample of this matico camphor was shown in the recent exhibition at Vienna by Messrs. Schimmel and Co., and some crystals transmitted to Professor Flückiger by this firm have been examined by Herr Kügler (*Berichte*, xvi., 2841). The melting point was found to lie between 89° and 103° C.; but after repeated recrystallization it became constant at 94° C., a yellow amorphous resinous matter, to which the variation was probably due, being left in the mother-liquor. The purified camphor was readily soluble in alcohol, ether, chloroform, benzol and petroleum spirit; it was not attacked by aqueous solutions of caustic alkalies, and when placed on the surface of water had a rotatory motion. With dry hydrochloric acid gas it took an intense violet colour, passing immediately into blue and then green. Upon analyses it gave results corresponding with the formula $C_{12}H_{20}O$, and Herr Kügler thinks it will probably prove to be the ethyl compound of ordinary camphor,—$C_{10}H_{15}(C_2H_5)O$.

Signor Barbaglia announces the isolation of a new basic substance from *Buxus sempervirens* (*Annali di Chimica*, lxxi., 5), to which he has given the name "buxinidine." It is precipitated from a concentrated alcoholic solution, together with parabuxine, by oxalic acid, and is separated from the parabuxine by means of ether, in which it is insoluble. It is described as forming a snow-white amorphous powder, insoluble in water or ether, slightly soluble in alcohol. The author appears to be unaware that a third basic principle has been isolated from this plant by Dr. Alessandri and named buxeine (*Pharm. Journ.*, [3], xiii., 23); this latter, however, would appear to differ from buxinidine in more than one respect, and is soluble in ether.

The want of agreement between different authors as to the composition of saponin has induced Dr. Schiaperelli to investigate the subject afresh (*Annali di Chimica*, lxvii., 65). *Saponaria officinalis* root was exhausted with boiling alcohol and the impure saponin that separated upon standing was repeatedly redissolved in hot alcohol and treated with animal charcoal. As it still retained inorganic matter, a cold saturated aqueous solution was treated with a similar solution of barium hydrate. The resulting precipitated barium-saponin was decomposed with a current of carbonic acid gas, the last trace of barium removed by means of a little dilute sulphuric acid, and the filtrate then evaporated to a syrupy consistence and precipitated with ether-alcohol. After repeating this operation several times and drying over sulphuric acid, a snow-white product was obtained quite free from inorganic constituents, and giving analytical results corresponding to the formula $C_{32}H_{54}O_{18}$, which is the same as that finally adopted by Herr Rochleder (*Pharm. Journ.*, [3], vii., 489). This saponin was amorphous and odourless, was an energetic sternutatory, had a disagreeable taste and a poisonous action, and was lævogyre; it dissolved very freely in water, less so in alcohol, and was almost insoluble in ether, benzine and chloroform. It had the peculiar property of preventing the separation of substances insoluble in water, retaining them apparently in a kind of colloidal condition. It is probably this property that allows of the use of a preparation of soap bark as a pseudo-emulsifying agent. When carefully heated with dilute acid in a water-bath this saponin splits up into a sugar possessed of very slight optical action and a micro-crystalline substance having the composition represented by the formula $C_{40}H_{66}O_{15}$, and differing, therefore, from the "sapogenin" of other authors. It is proposed that this decomposition product shall bear the name "saponetin."

Some months ago Professor Plugge separated from the Japanese plant *Andromeda japonica*, Thunb., a poisonous principle to which he gave the name "andromedotoxin." He has since made an examination of *Andromeda polifolia*, Linn., which grows wild in some parts in Germany and reports (*Archiv*, xxi., 813) that he has discovered the same principle in that plant. Although very little is known respecting any poisonous principles in plants of this genus, Guibourt mentions in his 'Natural History of Drugs' that the narcotico-acrid properties of *Andromeda polifolia* render it very injurious to sheep. Another crystalline body was separated from *A. polifolia*, which Professor Plugge says is probably identical with the "asebotin" isolated by Professor Eykman from the Japanese plant and which was considered to differ from arbutin only by the elements of water (*Pharm. Journ.*, [3], xiii., 798).

"Jambu assu" is said to be the local name of a plant indigenous to Brazil and employed in that country as a stimulant in low fevers as well as an antiperiodic; it is reputed also to exercise a specific influence over the uterus. A sample of the drug, consisting of a mixture of stems and roots, has been submitted to a chemical examination by Dr. Lyons (*Therap. Gaz.*, iv., 450), who reports that he has separated from it a crystalline neutral body, an alkaloid which in solution has a somewhat bitter and characteristic taste, a peculiar acid, an essential oil and a soft resin. It is doubtful whether any action that the drug may possess is attributable to either of the first three substances; but the volatile oil and the resin, which are removed in combination by extracting the alcoholic extract with hot petroleum benzine, both possess the peculiar pungency of the drug. Dr. Lyons appears to think that the resin is really the active constituent of the oleoresin and he describes it as being rather sparingly soluble in petroleum benzine, soluble in ether, alcohol and chloroform, almost insoluble in water and sparingly soluble in alkaline solutions. The plant from which the drug is derived has been referred to *Eugenia Jambos*, Linn., but this is thought to be probably a mistake.

The use of β-naphthol as a substitute for tar preparations in diseases of the skin has been stated by various observers to have been followed by toxic symptoms and irritation of the skin. In order to test the correctness of these statements, experiments have been made on rabbits and human beings by Dr. Shoemaker, and he reports (*Boston Med. and Surg. Journ.*, Nov. 8, p. 442) that subcutaneous injections, and even 2 and 4 grain pills every three hours, failed to produce any effect upon rabbits, except apparently to increase their appetite, whilst his assistants took increasing doses until they reached 5 grains twice daily, the principal results produced being a sensation of great warmth in the epigastric region after each dose, that passed away quickly, leaving a slight vertigo, buzzing in the ears and evidence of cerebral hyperæmia. Dr. Shoemaker points out that naphthol is apt to be contaminated by various bye-products, to which the pungent and disagreeable odour of the ordinary commercial naphthol is due; but if these be removed by passing a rapid current of steam through an aqueous solution it can be obtained in silvery crystalline scales and quite inodorous. In this condition, he says, it is a disinfectant and antiseptic of great value, superior in this respect to carbolic acid, and so far as his experience goes, never exercising any dangerous influence upon the human organism.

M. Guérin proposes to use crotonol, the vesicating principle of croton oil, in the preparation of blistering plasters, which he says are very active and are free from the inconvenience sometimes attending those having a basis of cantharidin (*Répertoire*, xi., 534). The crotonol can be obtained sufficiently pure for this purpose by shaking together in a flask equal parts of croton oil and 90 per cent. alcohol, and allowing the mixture to stand, when it separates into two layers. The alcoholic layer, which contains all the active principle, is then removed and heated in a water-bath until all the spirit is driven off, leaving an oily liquid a little more viscous than croton oil. A piece of linen of the size required is attached to diachylon plaster by simple pressure of the hand, and upon this sufficient crotonol is poured to completely saturate it.

Dr. H. L. Snow, in a note in the *British Medical Journal* (December 8, p. 1125), directs attention to the value of St. John's wort (*Hypericum*) in the prevention and cure of bedsores. The preparation used by him is described as a compound oil of hypericum, but he gives a recipe for what may be termed a simple oil, as follows:—Fill a bottle half full with the flowers of St. John's wort; olive oil is then to be added, and the bottle is to stand in the sunshine for a few days till the oil becomes of a deep red colour; it is then fit for use. The oil is brushed over the sore two or three times daily with a feather. It is unfortunate that Dr. Snow has omitted to say what species of *Hypericum* should be used, since the name "St. John's wort" and *Hypericum* are both used in a general sense. It would be desirable also to know whether he intends the recipe to be used as a substitute for the compound oil.

In the *Lancet* (Dec. 1, p. 946), Dr. A. H. Baines calls attention to the value of nitrite of sodium in cases of epilepsy not amenable to bromides, but reiterates the caution as to the necessity of giving the salt in doses of not more than 2 or 3 grains, and of obtaining it pure.

Hyposulphite of sodium is mentioned by a correspondent of the *British Medical Journal* (Dec. 22, p. 1268) as an excellent disinfectant for destroying the horrible odour of carcinoma uteri. The salt is used in solution of the strength of 1 lb. to 1 pint of water.

Dr. Kennedy, in the *Philadelphia Medical Reporter* (Nov. 24), recommends the following method of administering salicylate of sodium, as being more pleasant than the usual form. ℞. Sodæ bicarb. ℥ij; acid. salicylic. ℥iij; glycerinæ, aquæ āā ℥ij. A teaspoonful every four hours. The glycerine prevents the too rapid evolution of the carbonic acid, and helps to keep the salicylate in suspension (*Med. Times and Gazette*, Dec. 22, p. 722).

Dr. T. J. Hudson directs attention in the *Lancet* (December 22, p. 1081) to the comparative value of the bromides and iodides of potassium and sodium. He considers that the sodium bromide is less liable to produce depression, dyspepsia, or acidity, while the taste also is less objectionable. It constipates rather than the reverse, and has greater tonic action than the potassium salt, but is contra-indicated when there is much phosphate in the urine. In whooping cough the potassium bromide is, however, more effectual than the sodium salt. In renal disease, rectal cancer, or other cases in which opium is inadmissible or injurious, the sodium salt answers best, and in all cases in which the action of the haloid element is desirable the sodium salts are to be preferred.

Not long ago the use of the burdock in medicine as an alterative in skin diseases was pointed out in these columns, and now it is stated (*Garden*, Dec. 22, p. 545) that the root is being introduced in France as a vegetable, under the auspices of the Acclimatization Society. It is said to resemble salsafy in flavour, and as an antiscorbutic vegetable may possibly be of use as a diet on sea voyages. The root of *Canna edulis*, the tous-les-mois plant or capucho, the starch of which is well known to microscopists as one of the largest kinds, has been pronounced when cultivated in France to be worthy of taking rank with the vegetables commonly grown in gardens at the present time. The 500 franc prize for the introduction of an esculent which can be used as human food has been awarded to M. Paillieux for this root.

Dr. W. G. Balfour, of Bombay, has announced the discovery in the blood of the banela fish, commonly known as Bombay ducks, of a bacterial organism resembling those which Dr. Koch found in the intestines of cholera patients in Egypt. Dr. Balfour had lately pointed out that the consumption of certain kinds of fish at particular periods of the year seemed to play a part in the production of cholera (*Lancet*, Dec. 15, p. 1058).

In a communication to the *Lancet* (Dec. 8, p. 984), Mr. Lawrence puts forward the theory that typhoid fever is capable of being set up *de novo* by bovine evacuations. In support of it he cites a number of cases that came under his observation while practising medicine in South Africa, in which, although the sparse population of the country was favourable to the tracing of infection, no connection with a previously existing case of typhoid could be detected, whilst there was always evidence of the access of cattle manure to the drinking water. In no case was he able to ascribe the disease to horse manure or to sheep manure, the latter of which, at the large sheep farms of the Boers, is said to lie in enormous quantities close by their dwelling houses. It certainly is a curious fact, as pointed out by Mr. Lawrence, that many typhoid epidemics of which the history has been traced in this country have originated from dairies, although this has hitherto usually been attributed to the great susceptibility of milk to contract contamination.

A case of poisoning by the berries of *Bryonia dioica* is mentioned in the *British Medical Journal* (Dec. 1, p. 1067), in which the patient, a child four years of age, recovered after the use of an emetic of 20 grains of ipecacuanha and 10 grains of sulphate of zinc, with a warm poultice over the abdomen and a dose of senna tea. The subsequent feverishness was met with salines.

A case of poisoning by three drachms of aconite liniment is recorded in the same journal, in which the patient, aged about sixty, died in less than two hours. In this case a hot poultice over the epigastrium proved useful; but medical aid was probably called in too late, as no mention is made of apomorphia being used, or of the other remedies mentioned in Murrell's little work 'On what to do in Cases of Poisoning.'

Mr. A. Nesbitt in the *Gardeners' Chronicle* (p. 763, Dec. 15) queries the oft-repeated assertion that honey made from the flowers of *Rhododendron ponticum* is poisonous, and even that the plant itself is so. He says that he has observed lambs eating a small quantity of the leaves either of *R. ponticum* or hybrids of that plant and no bad result followed. He suggests that it is possible that as the flower of the oleander is more like a rose than the rhododendron, it is probable that the former was the plant from which the honey was obtained which poisoned Xenophon's soldiers, the oleander being well known to be poisonous.

The Rev. C. Woolley Dod, in p. 793 of the same journal, contributes an interesting note which throws some light upon this point. He remarks that there were apparently two kinds of poisonous honey met with in Pontus, one found near Heraclea and the other near Trebizond, the former being attributed by Pliny to a plant called "ægolethon" or goat's bane, the other to a plant which both he and Dioscorides called "rhododendron;" but they also used the name "nerium" for it. The latter Sibthorp has identified as *Nerium oleander*. Mr. Dod can find no direct evidence that *Rhododendron ponticum* is poisonous; but *Azalea pontica*, which occurs in profusion near Trebizond, about ten miles from the coast, he believes to possess poisonous properties similar to those attributed to *Kalmia latifolia*. It is a noteworthy fact, if correct, that no species of *Rhododendron* is known to be poisonous, while members of the other Ericaceous genera, *Azalea*, *Kalmia* and *Andromeda*, possess poisonous properties. M. Peysonnell, in a treatise published in Paris, in 1787, mentions among the annual exports from Taman, on the east side of the Sea of Azov, 500 quintals (about 25 tons) of honey collected in Abaza, a region on the north-east coast of the Black Sea, extending up the west slope of the Caucasus. This honey was called mad honey (miel-fol), and its use was for mixing with intoxicating drinks to increase their effects. It is remarkable that Pliny uses the same word "mad honey" for the poisonous honey of Pontus.

It has generally been supposed that the pretty little microscopic alga, *Volvox globator*, is a hollow sphere. Mr. Levick, however, has demonstrated that this is not the case (*Journ. Roy. Micr. Soc.*, December, p. 889), but that the alga consists of a skin containing matter apparently of a gelatinous consistence, which retains its spherical shape when the outer skin is stripped off, the skin collapsing when empty. The gelatinous contents are, however, so exceedingly transparent that they can only be seen in a coloured fluid. If a gathering of volvox be strained and placed in water containing carmine or coloured matter, the carmine can be seen adhering to any one of the spheres which has part of the surface removed. Sections have also been cut when the plant is frozen, which, when thawed, retain a sufficient density to support particles of carmine, dirt, or other solid matter.

Herr J. M. Hetlinger has investigated the electrical phenomena attending the germination of seeds of *Vicia*, *Faba*, *Zea Mays* and *Biota orientalis* (*Journ. Roy. Micr. Soc.*, Dec., p. 867), and finds that in these plants, in all stages of development, from the time of the protrusion of the radicle through the testa to the earliest appearance of the first foliage leaves, the galvanometer indicated a current from the cotyledons to the radicle, caused by the electro-negative condition of the latter and the electro-positive condition of the former. Every point of the root of the secondary roots, and of the first foliage leaves, and especially of the tigellum, was electro-negative in relation to the cotyledons, but with decreasing intensity the nearer to them. This line of investigation seems to be one which might possibly be turned to account in gaining a further insight into the direction followed by the sap in different plants and of some of the chemical and vital processes of plant life.

The *Journal of Botany* for December records the discovery of *Lobelia urens* in Cornwall, between Lostwithiel and St. Veep, but speaks of the station near Axminster as being the only Devon one. There is, however, very good authority for stating that it grows also in North Devon, where it was found by Dr. Wainwright. It is fortunate that the plant has a perennial root or it would speedily be destroyed in the few places where it is indigenous, from the rapacity of collectors, who have been seen to take it away in one case by the basketful and in another by hundreds of specimens. Provided that the root is not pulled up, however, the "locality" will not be easily destroyed. An illustration of all of the new *Naias* (*N. marina*) is given in the same number of the *Journal of Botany*. Dr. Hance also describes a new podophyllum, *P. versipelle*, found near Canton, so that, with the Formosan one recently described, there are now four species of the genus—*P. peltatum*, *P. Emodi*, *P. pleianthum* and *P. versipelle*. *P. versipelle*, like *P. pleianthum*, has purplish flowers, but in the former the leaves are opposite and the flowers on the axil. The new species is said to vary remarkably in the outline of the leaf, from a square parallelogram, triangle or pentagon to a circle, and would, therefore, form an interesting addition to our Botanical Gardens as a morphological curiosity. The finding of two species in the extreme east of Asia illustrates the relationship which exists between the Chinese flora and that of the United States; but it is a curious fact that the Asiatic species have only a single row of stamens. As in *P. Emodi*, the new plant has a prolongation above the lower leaf, which Dr. Hance regards as a continuation of the aerial stem, the petiole of the upper leaf arising only just above the insertion of the flower or flowers.

Within the present month, too, another new British plant, *Carex trinervis*, has been detected by Mr. Arthur Bennett in the Herbarium of Mr. H. G. Glasspoole, where it has lain *perdu* for fifteen years. The specimen was collected near Yarmouth. The numerous recent discoveries in this side of England point to the conclusion that a comparison of the flora of our eastern counties with that of the opposite coast of Holland might lead to the detection of other species that might be expected to occur.

THE SOLUBILITY OF CALCIC HYDRATE IN WATER AT DIFFERENT TEMPERATURES.*

BY THOMAS MABEN.

In the course of an able paper on "Lime Water: its Preparation, Preservation and Estimation," read some time ago by Mr. Abraham, of Liverpool, and subsequently published,† the author stated that he had found a difficulty in maintaining his lime water at the proper strength. On investigating the cause of this he was led to the conclusion that the difference was due to increase of temperature, and he indicated that the solubility of calcic hydrate fell from 0·56 grain CaO per fluid ounce at 60° F. to something like 0·5 grain at 70° F.

Having had occasion in July last to give a few notes (which were afterwards published in an extended form‡), on the same subject before a local association, I undertook at that time an investigation as to the effect of temperature on solubility, and though my experiments were confirmatory of Mr. Abraham's to a certain extent, the results did not show such a marked difference as his had done. I have recently repeated these experiments with more care than before, and now bring the results before you in the hope that they may prove of some interest.

I have been much surprised, in looking into various authorities, to find that great differences of opinion prevail regarding the solubility of calcic hydrate. A few of these may be noted. At 15° C. calcic hydrate is held in solution to the extent of 1 part CaO in 781 parts water, according to Squire; 780 (Miller and Bineau); 778 (Dalton); 776 (Paris Codex); 764 (Hager): 750 (United States Pharmacopœia); 730 (Wittstein); 500 (Ure), and 450 (Davy). At 100° C. 1 part is dissolved in 1560 water, according to Miller; 1500 (Bineau); 1350 (Wittstein); 1305 (Hager); 1300 (United States Pharmacopœia), and 1270 (Dalton).

According to the German Pharmacopœia *aqua calcaria* should contain calcic hydrate equal to from 0·43 to 0·49 gr. CaO per fluid ounce, the United States Pharmacopœia gives the amount in solution as about $\frac{1}{2}$ grain, while the British Pharmacopœia requires *liq. calcis* to contain ·56 gr., *i.e.*, to be as nearly as possible a saturated solution.

According to Storer, Dalton disputes the correctness of the statements of observers who say that water takes up $\frac{1}{400}$ or $\frac{1}{450}$ its weight of lime, the fact being, he says, that few have tried the experiment with due care.

In estimating the strength of solutions of calcic hydrate it is of the utmost importance that we should ascertain correctly the temperature at which the solutions pass through the filter. This is a matter of considerable difficulty. I have found that different methods give quite different results, and there is not the slightest doubt, in my opinion, that had the authorities quoted carefully followed an uniform system their results would have been much more in accord than they are. It is sufficiently obvious that out of the eight or nine different solubilities quoted not more than one can be absolutely correct, and while the question is not one of crucial importance it would be extremely interesting if by some means or another the real figure could be arrived at.

In the experiments which form the basis of this communication, I adopted the following method, it having been found to give the most constant results.

For the lowest temperature I placed a glass beaker containing calcic hydrate and distilled water in a freezing mixture till the thermometer fell to 0° C., and ice began to form. The liquid was then filtered, zero being maintained by placing the funnel also in a freezing mixture. The temperatures from 5° C. to 15° C. present no special difficulty, as they are easily obtained by adding hot or cold water to the beaker till the required point is reached and filtering in the usual way. Comparatively little variation takes place when the surrounding atmosphere indicates from 10° C. to 12° C. From 15° C. to 80° C. I made use of the water-bath. A flask containing lime and water was placed in the bath, and as soon as the contents reached the required temperature, the mixture was filtered through a funnel placed in the ordinary funnel space in the bath. The water surrounding the funnel, being always at the same temperature as that surrounding the flask, it was hardly possible for any variation to take place, but in order to ensure accuracy the thermometer was used in the funnel as well as in the flask. For the temperatures above 80° C. the solutions were heated over the naked flame and passed through a funnel kept in boiling water. It is exceedingly difficult, unless with special appliances, to filter at the boiling point, and I had to be content with what I have described. Strictly speaking, the maximum point reached would be from 98° to 99 C.

For the sake of convenience quantities by volume were taken, a small graduated flask being employed as a measure.

The amount of lime in solution was ascertained volumetrically, decinormal nitric acid being used. This acid is preferable to oxalic, as calcic nitrate being soluble in water, there is no danger of the exact point of neutrality being obscured by the presence of a precipitate.

Calcic oxide, perfectly free from all impurities, was made use of, after having been slaked with distilled water. Incidentally, I may remark that the heat generated in "slaking" the lime rose to the very high point of 205° C.

The results which were arrived at have been tabulated in three ways for the sake of convenience, and are appended. The figures are in each case calculated from the mean of three titrations, but where thought necessary corroborative results have been obtained by additional experiments.

It will be observed that the solubilities are expressed in terms of calcic oxide. I express them so, in accordance with custom, although it is apparent that the calcium exists in solution as hydrate and not as oxide.

I am unwilling to close this note without a few words as to its practical bearing upon the *liquor calcis* of the British Pharmacopœia. Repeated proceedings have been instituted against druggists for the sale of defective lime water, and cases have been reported where the strength was as low as 0·1, 0·2 and 0·3 gr. CaO per fluid ounce. Several hypotheses might be started to account for this state of things, and I shall briefly allude to one or two of these.

* Read at a Meeting of the North British Branch of the Pharmaceutical Society, December 19.

† *Pharm. Journal*, [3], xiii., p. 433.

‡ *Chemist and Druggist*, 1883, p. 390.

In the first place, it is obvious that the variations of temperature which naturally occur really exercise comparatively little influence on the strength of lime water, for it can rarely happen that the temperature of a shop will rise above 32° C. (90° F.), and yet at that point, water holds in solution about 0.5 gr. CaO per fluid ounce.

Neither can we account for these faulty waters on the hypothesis that undistilled water had been used in their preparation, unless, indeed, the water had been altogether exceptional in permanent hardness. I have found that a water containing about 10 grains of total solids per gallon gives lime water of full strength. At the same time this does not alter the fact that only distilled water should be employed in preparing *liquor calcis*.

Other two hypotheses remain, either of which would furnish a sufficient cause for even the weakest lime water. One is that the calcic hydrate, not having been properly stored, had almost entirely changed its constitution and become carbonate; the other, that the solution, after decantation or filtration, had been so badly kept that the lime originally present had all or nearly all been precipitated. It is a well-known fact, and one which is daily made use of by the agriculturist in the application of lime to the soil, that if burnt lime be exposed to the atmosphere even for a very short time, it passes over into the milder form of carbonate. The same reaction, of course, takes place on the shop shelves, and if slaked lime is not kept in an air-tight vessel, it necessarily follows that it will deteriorate, owing to the absorption of CO_2. If, forgetting this, any pharmacist has been careless in storing the slaked lime, it need not be wondered at if his lime water is weak.

I have found that lime water can be made of full strength with calcic hydrate, mixed with 15 per cent. of carbonate; with equal parts of hydrate and carbonate I obtained 0·5 gr. CaO per fluid ounce; with 25 per cent. hydrate and 75 carbonate, 0·4 grain; and with 10 per cent. hydrate and 90 carbonate, the amount dissolved was only 0·1 grain.

It is stated in almost every text-book that calcic carbonate is insoluble in water, and if this is so, these results are to say the least very singular. I have been able, however, to find several authorities who differ from the popular belief. Among others, Thorpe* states that a litre of water dissolves 0·1 gram $CaCO_3$, that is in the proportion of 10,000 to 1. My own experiments go to prove that 40,000 to 1 is nearer the mark, but whatever the solubility is it is quite appreciable, and the alkalinity can readily be estimated.

The U.S. Pharmacopœia states that "the alkaline reaction of the liquid entirely disappears after it has been saturated with carbonic acid gas, and the excess of the latter has been expelled by boiling (abs. of alkalies or their carbonates)." This, however, is not so; the liquid after boiling is still alkaline, though of course not to any large extent, and the test as it stands is therefore worthless.

The other hypothesis is similar in principle to that just explained. If after filtration, the lime water is kept in vessels of too large a capacity, or in unstoppered bottles, calcic carbonate is rapidly deposited. Even when most carefully preserved, this takes place to a certain extent, the coating of carbonate inside the shop bottles being a familiar sight to all of us. This is of itself quite sufficient to account for occasional inferior specimens, and it will be remembered was the defence urged at a recent trial; but if there is reason to suspect that the lime water is habitually weak, the explanation would probably be found in the fact that the stock of lime was for the most part in the form of carbonate.

It is difficult to understand why the presence of carbonate should prevent the solution of the hydrate when the latter is present in sufficient quantity to saturate the water, but I have repeatedly proved that it does so, whatever be the explanation of the fact.

HIPPURATE OF SODA.*

BY PETER BOA.

At our last meeting there was exhibited a specimen of hippurate of soda. This salt is perhaps deserving of more than the incidental notice which it then received, on account of the recent suggestion of Dr. Garrod to employ the alkaline hippurates in diseases arising from excess of uric acid in the system. In the course of his experiments he made the observation that hippuric acid, when allowed to remain in contact with uric acid, caused the disappearance of the latter.

It may be noted that there are three forms in which nitrogenized waste is eliminated from the system by the kidneys, viz.:—as urea, uric acid and hippuric acid. Of these uric acid is the least soluble. It is practically insoluble in water, and the salts which it forms are but slightly soluble. On account of this characteristic it is, although forming only a very small part of the excreted waste, frequently the cause of disease, owing to its liability to form concretions in the kidneys, giving rise to gravel and calculus, and in the form of urate of sodium it may deposit in certain tissues, and give rise to gouty and rheumatic symptoms.

* Read at a Meeting of the North British Branch of the Pharmaceutical Society, December 19.

In herbivorous animals the renal excretions rarely contain uric acid, but hippuric acid is always present. Uric acid is probably formed at one stage, but the presence of hippuric acid in considerable quantity effects its decomposition. Hippuric acid forms salts which are extremely soluble.

To approximate, therefore, the excretions from the kidneys of man to those of the herbivora, is to make an important step towards the prevention or removal, as the case may be, of the cause of diseases which arise from the defective elimination of uric acid. This may be attained by the employment of such a salt as hippurate of soda.

Dr. Garrod says: "There is no doubt that if hippurate of soda be added to a blood serum which shows the presence of a urate, the latter is soon removed from it."

I make these preliminary remarks merely to show on what grounds the introduction of this remedy is based. In view of the salt coming into general use, I have made a number of experiments in regard to its behaviour towards other substances with which it might be administered in combination.

There are only two forms in which we shall likely be called upon to dispense it, namely, in powders and mixtures, and in regard to these only have I made experiments. Avoiding details, I shall summarize the results which seem worth recording.

(1) *Powders.*—The hippurate of soda itself, dispensed in powder form, keeps quite well in paper. Combinations of the salt with lithia carbonate and citrate and bicarbonate of potash and soda, put up in powders in the usual way and kept for a fortnight, were found on examination to be in as good condition as when prepared.

(2) *Mixtures.*—Like all alkaline salts the taste of hippurate of soda is disagreeably saline. I have tried a number of combinations with the object of rendering its administration as pleasant as possible, and the results may be briefly stated.

Chloroform water or spirit of chloroform seems to make it more disagreeable, rendering it almost nauseous.

Infusion of calumba disguises the saline taste, and where the bitter is not an objection, affords an eligible vehicle.

The most agreeable mixtures, however, are obtained by employing syrup and peppermint water or glycerine and cinnamon water.

The following examples may suffice:—

(1)	℞ Sodæ hippurat.	gr. 80
	Lithiæ carb.	gr. 24
	Glycerin	ℨiv.
	Aq. cinnam. . . . . ad	℥viij.
M.	Sig. One-eighth part for a dose.	

(2)	℞ Sodæ hippur.	ℨij
	Potass. citrat.	ℨiij
	Syrupi	℥vj
	Aq. menth. pip. . . . . . . ad	℥vj
M.	Sig. Tablespoonful for a dose.	

The addition of an alkaline carbonate or citrate as given in the foregoing is desirable, so as to imitate the condition of the renal excretion of the herbivora, which is alkaline, that of man being usually acid.

The salt is very soluble. Fifty grains dissolve in thirty minims of water, forming a syrupy liquid. The dose may be from 10 to 15 grains.

THE PREPARATION OF QUASSIIN.*

BY ADRIAN AND MOREAUX.

Quassiin, the active principle of *Quassia amara* or Surinam wood, has long been presented in a more or less impure extractive form. The authors have studied the different published methods of extraction and have arrived at the conclusion that some of these methods give but a defective product, while the others, though producing purer quassiin, remove but a small portion of the bitter principle contained in the wood.

After quoting the methods for extraction given by Soubeiran, Pelouze, Wurtz, Wiggers and Christensen, the authors state that by the following process, which is their own, a purer and more abundant product is obtained.

Very sound wood reduced to thin shavings is exhausted by the aid of boiling distilled water, either by displacement or by decoction, carbonate of potash being added to the extent of 5 grams per kilogram of quassia. The liquor is then concentrated by evaporation, first by the open fire, afterwards in a water-bath, to the consistence of a soft extract; a mean of 60 grams per kilogram of quassia being obtained. The extract is afterwards suspended in hot 90° alcohol, and after standing a few moments the supernatant alcohol is decanted; the process being repeated a second and third time, so as to thoroughly exhaust the extract. The alcoholic liquor is allowed to stand twenty-four hours, during which it deposits extractive matter and salts dissolved by the hot alcohol; the liquid should then be decanted, and sulphuric acid diluted with ten times its weight of 90° alcohol added until a precipitate is thrown down, from 2 to 2½ grams being necessary for each kilogram of quassia. The liquor is then filtered, milk of lime added in the proportion of 12 to 15 grams per kilogram of wood (or 4 to 5 grams of caustic lime), and after some hours' contact, it is passed through muslin and the deposit washed with alcohol and pressed, as it is very spongy and contains much alcoholic liquor.

The liquor being alkaline after the treatment with lime it is neutralized by a current of carbonic acid, and then again filtered. Thus prepared, the liquor has a light amber tint. It now remains only to distil the alcohol and to dry the residue from the distillation. Each kilogram of quassia yields by this process about 8 grams of a friable and easily pulverized product, which is the amorphous quassiin of Adrian.

If, instead of amorphous, it be desired to obtain crystallized quassiin, the distillation should be stayed while there yet remains a small quantity of alcohol in the product, which is then poured boiling upon a moistened filter to separate the resin. This filter should be so placed that the liquor may be received in a porcelain capsule. The remainder of the alcohol is then evaporated by heating to 80° C., and as the alcohol volatilizes, the quassiin crystallizes out and is deposited. As soon as the liquor contains no more alcohol, it is withdrawn from the fire; when in a few minutes and before the liquor has quite cooled it forms a crystalline mass. When quite cold, the mother liquor is decanted and the crystals are washed several times with distilled water. The quassiin thus obtained is not quite pure; it still contains some resin and uncrystallizable quassiin. To purify it, it is dried, and then dissolved by heating it in twice its weight of 95° alcohol. It is then placed to crystallize in a funnel with a very short neck closed by a cork stopper; in cooling, the quassiin crystallizes, and after ten or twelve hours, forms a mass. The stopper is then removed and the alcohol which has been used in crystallizing is displaced by 90° or absolute alcohol, in order to wash the quassiin. As the crystallizing liquor draining away is replaced by fresh alcohol, the coloured quassiin is seen to become white; a second crystallization suffices

* From the *Rép. de Pharm.*, n. s., vol. xi., pp. 246—50, (Juin, 1883).

to render it very pure; the result is from $1\frac{1}{4}$ to $1\frac{1}{2}$ gram per kilogram of quassia.

The mother liquor and the wash waters of the first crystallization retain a considerable quantity of quassiin, which it is difficult to entirely extract. A large proportion may be obtained by shaking these liquors several times with chloroform, which dissolves the quassiin and separates very easily from the aqueous liquor. The chloroform is distilled off, and in this way the non-crystallizable quassiin is obtained, it being deposited from the alcoholic solution as a granular resinoid substance, which is very easily softened by heat. Its bitterness is nearly equal to that of the crystallized quassiin. Repeated treatments with chloroform have failed to remove from the aqueous solution the whole of this quassiin, which seems to be combined with mineral salts that it still contains.

The alcohol which has been used in the crystallization, as well as that used in the washing, contains also in solution a little quassiin both crystallizable and uncrystallizable, which may be obtained by the same process as above described.

Résumé.

	Crystallizable quassiin.	Uncrystallizable quassiin.	Mineral salts.	Resin and other organic matters.
Viscous brown amorphous quassiin in 100 parts contains	00 to 00	12 to 15	35 to 40	45 to 50
Yellow amorphous quassiin in powder contains in 100 parts . . .	18 to 20	18 to 20	25 to 30	30 to 35

In brown quassiin, potassium salts predominate.

In yellow quassiin, calcium salts.

Crystallized quassiin is white, light, very soluble in chloroform, soluble in about 90 parts of cold absolute alcohol, in 35 to 40 of 80° alcohol, scarcely soluble in ether, and soluble in about 300 parts of hot water, from which it recrystallizes on cooling.

Uncrystallizable quassiin is very soluble in absolute alcohol, more soluble in ether than crystallized quassiin, and less soluble in water.

BISMUTH SALICYLATE.*

BY L. WOLFF, M.D.

In a recent number of the *American Journal of Pharmacy* mention was made of this article as a new remedial substance, along with an interesting account of its use and some of its properties. The *New Remedies*, as well, had notes upon the subject in both the September and October numbers, giving therein, also, directions for its preparation, which, however, are not sufficient to obtain a pure salicylate, but only a mixture of the subnitrate and salicylate thereof.

Bismuth is well known to exist in combinations both as bismuthous and bismuthyl salts, the former on addition of water changing into the latter group. Weaker organic acids, however, will not enter into combination directly with so-called metallic bismuth, and we have to depend, therefore, for its preparation on double decomposition with other salicylates the bases of which have greater affinity for the acid radical of the bismuthous salt. The bismuthous salts being precipitated from their acid solutions by water, would in such decompositions give rise to the precipitation of considerable bismuthyl salts in addition to the salicylate so formed. Thus, as proposed in the September number of *New Remedies*, if an acid solution of bismuth nitrate be employed, a mixture of bismuthyl nitrate and salicylate with salicylic acid would inevitably result. If, as proposed in the same journal of October, an acid bismuthous chloride solution were used, a similar result with bismuthyl chloride would ensue. As bismuthyl carbonate cannot be decomposed by salicylic acid, a direct salicylate is thus impossible, though bismuth teroxide, if freshly prepared from bismuthyl nitrate, with solution of sodium or potassium hydrate, will combine with salicylic acid when boiled with a concentrated solution of the acid for some time.

The reaction is a direct one, and would be expressed as follows:—

$$Bi_2O_3 + 2\,C_7H_6O_3 = 2\,BiOC_7H_5O_3 + H_2O.$$

As in this process, however, there seems to be always more or less undecomposed bismuth teroxide present, it is safer to produce it by double decomposition, with proper measures preventing the formation of other bismuthyl salts than the one desired.

After experimentation to that end, I found that a glycerine solution of crystallized bismuthous nitrate bore dilution with 1 to 2 parts of water before precipitating the bismuthyl nitrate, and acting on this I made a concentrated solution of sodium salicylate, with which I decomposed the glycerine solution of crystallized bismuthous nitrate, obtaining thus a bismuthyl salicylate, sodium nitrate, free nitric acid, salicylic acid and water, which were removed with water, and the still adhering salicylic acid removed by washing with hot water and subsequently alcohol. The reaction occurring under these circumstances with the sodium salicylate, as given in the U.S. Pharmacopœia as $2\,NaC_7H_5O_3.H_2O$, would be expressed:—

$$Bi3NO_3.\,5\,H_2O + 2\,NaC_7H_5O_3.H_2O = BiOC_7H_5O_3 + 2\,NaNO_3 + C_7H_6O_3 + NO_3H + 5\,H_2O.$$

As the bismuthyl salicylate treated with a concentrated solution of sodium bicarbonate yielded bismuthyl carbonate and sodium salicylate, I inferred that bismuthyl nitrate would yield, also, on boiling with a concentrated solution of sodium salicylate, a bismuthyl salicylate, which I found to be the case, the reaction being as follows:—

$$2\,BiONO_3H_2O + 2\,NaC_7H_5O_3.H_2O = 2\,BiOC_7H_5O_3 + 2\,NaNO_3 + 3\,H_2O.$$

The precipitate, being well washed with hot water, presented the same appearance as by either of the previous methods, and when dried and combusted on the platinum foil grew dark brown, and burnt off to the greater part with evolving phenol vapours.

The salicylate of bismuth presents a slightly pinkish appearance and is of a granular consistence, which is not readily overcome to an impalpable powder in the mortar. Under the microscope it is easily distinguishable from the subnitrate by being of a distinct granular character, the granules of even size, reminding of the conidia of fungoids, while the former consists of uneven broken crystals.

In water, glycerin, alcohol and ether it seems insoluble while its solution in acids is probably due to its decomposition, and formation of bismuthous salts. Tests for its purity are the absence of acid reaction of water boiled with it (salicylic acid), its rapid combustion on platinum foil, with liberation of phenic odours, free from nitrous acid vapours, and lastly its distinct granular appearance without crystalline fragments under the microscope (bismuthyl nitrate).

If it proves what has been claimed for it, it will certainly be a most important addition to our store of remedial agents, but its slow demand amidst the vast material for its application where it could be certainly used with impunity leaves the latter question somewhat in doubt.

THE BRITISH PHARMACEUTICAL CONFERENCE AND THE ENTERTAINMENT OF VISITORS AT ITS MEETINGS.

IT may seem inappropriate at this festival season to say anything that has even the appearance of limiting the exercise of hospitality, but the decision arrived at by the Executive of the British Pharmaceutical Conference last week, as recorded on another page, is so completely in accord with the course which has been repeatedly advocated in these columns that we feel pleasure in taking the earliest opportunity in giving it such endorsement as lies in our power. In the official statement of the objects of the Conference, "the encouragement of scientific research" takes priority of "the promotion of friendly intercourse amongst pharmacists," but we are by no means sure that this order represents the relative importance of these two objects so far as they are attainable by that body. For although there can be no doubt that a number of important researches have been initiated under the auspices of the Conference, there is no absolute reason why these should have been dependent upon the existence of such a stimulating influence, and possibly if the Conference had never been formed a large proportion of the valuable information that has been made known in papers read at its meetings would have seen the light in some other way, either by being brought before one of the societies in London or the provinces, or by being published directly in one of the technical journals. But we know of no other means by which the promotion of friendly intercourse between pharmacists can be effected so thoroughly as it is by the annual meetings of the British Pharmaceutical Conference in various parts of the country. It is for this reason that we have felt that any conditions that might tend to render these gatherings in the least degree burdensome to those taking part in them or to mar the prospect of their continuance should be most carefully avoided.

We are therefore pleased to learn that at the meeting of the Executive before referred to it was resolved that in future the expense of the luncheons which are usually provided on the days of meeting, and which are so popular among the members as a real convenience and as furnishing pleasant opportunities for social intercourse, shall be borne by those who partake of them. It was also resolved in the event of an excursion being organized in connection with any future meeting of the Conference the expense of conveyance shall be defrayed by those taking part in it. Now, without assuming in the slightest degree that the size of a town is, potentially or volentially, a measure of the hospitality of those who live in it, there is required but a small effort of the imagination to conceive of occasions when the existence of these resolutions will relieve the local organizers of the Conference meetings of a cause of much anxiety in respect to finances. At the same time in cases where funds are available the resolutions will impose hardly any restriction upon a proper desire to spend them, although it may be hoped that in all cases it will be understood to be the wish of the visitors that the hospitality should rather take the form of enabling them to make the most of their stay in a locality at a minimum of expense to any one. Nor in conceding to these terms need the resident members think that they are laid open to any imputation as to their generosity. The practice will be essentially in accord with that followed in connection with the two largest meetings of pharmacists on the continents of Europe and America,—those of the Deutsche Apotheker-Verein and the American Pharmaceutical Association. In the case of the former of these societies, the organization of the meetings, so far as relates to accommodation and excursions, is, we believe, undertaken by a local committee, as we presume it is intended to continue to be the case with the Conference, and a book containing a set of coupons is issued to each gentleman visitor at a fixed price, there being also usually a set of coupons for lady visitors at a lower price. In the United States a similar practice obtains, except that the fundamental arrangements for the entertainment of visitors are made and carried out by an "Entertainment Committee" nominated by the Association itself, the local members being left to supplement these or not as they may please. It will be apposite to mention that some little opposition having been manifested at Washington to this practice the subject was referred for consideration to a committee, which has since reported decidedly in favour of its continuance.

We take the opportunity, whilst writing upon the subject to refer to another reform that we hope one day to see accomplished, and that is the more complete separation of the meeting of the British Pharmaceutical Conference from that of the British Association. Originating, as the Conference did, on the occasion of the meeting of the British Association at Newcastle in 1863, it was only natural that for a time the young society should avail itself of any advantage which the gathering together in one place of many scientific men interested in the progress of pharmacy presented for holding its meetings. But the Conference is now strong enough to run alone, and ought no longer to lay itself open to the possibility of the sneer that it is merely a "side show" to the

Association. We know that there are still certain advantages to be derived from holding the two meetings about the same time and in the same town, not the least being that this plan best suits the convenience of persons who are members of both societies; but these advantages are probably more than counterbalanced by accompanying disadvantages, and we do not think the objections to an alteration are insuperable. As in the coming year the Conference will, for the second time in its history, break away from its sister Association, we hope the experience will be so satisfactory that its repetition may in succeeding years become the rule and not the exception.

At the recent meeting of the American Pharmaceutical Association, on the suggestion of Mr. J. W. Colcord, of Lynn, Massachusetts, a resolution was passed, asking the United States Congress to appropriate the sum of twenty-five thousand dollars to promote the introduction and cultivation of foreign medicinal plants in different parts of the Union. A similar resolution has since been adopted by the Massachusetts Pharmaceutical Association, and vigorous efforts are being made to secure the political support necessary for the passage of a Bill to that effect. In the meantime, we understand that Mr. Colcord has obtained a considerable quantity of seeds of *Rheum palmatum*, some of which he has distributed to various other persons interested in the subject, and some he has retained for his own experiments. The enormous range of climatic conditions comprised within the United States territory would offer many facilities for carrying out attempts at acclimatization on an extensive scale, and the experiments, if made, will be watched with great interest from this side of the Atlantic.

* * *

We see from the latest numbers received of the *Ceylon Observer* and the *Times of Ceylon* that Dr. Trimen has communicated to the public press copies of a letter that he had forwarded to us for publication, consisting of a reply to Mr. J. E. Howard's criticisms on points in the "Ledgeriana" controversy, to which reference has been made in our columns more than once. Dr. Trimen appears to have thought that a certain time having elapsed since the dispatch of the letter from Ceylon he might assume that it had already appeared in this Journal; but, in fact, the manuscript having been received by us simultaneously with the news of the death of Mr. Howard, it was thought advisable to delay its publication in order to give Dr. Trimen an opportunity of revising certain passages by sending him a proof.

* * *

The new Rules under the Patents Act of last session, relating to applications for and registration of patents and proceedings thereon, together with a list of fees and rules for appeal to the law officers, have just been issued. The rules appear to apply only to patents, so that we presume the existing regulations as to the registration of trade marks will continue in force, according to the provision made in the new Act, which comes into operation on the 1st of January.

* * *

An International Forestry Exhibition will be held at Edinburgh next year under the patronage of Her Majesty the Queen. Systematic collections of forest produce, specially illustrating the sources of supply and the method of manufacture in different provinces, will be exhibited, and are to be accompanied by reports. Prizes will be awarded, in the shape of diplomas, medals and money, to exhibitors of such collections; also for concise practical essays on various subjects connected with forestry, a list of which can be obtained from the Secretary, Mr. G. Cadell, 3, George IV. Bridge, Edinburgh. Among the subjects for essays may be noted two which are connected with pharmaceutical products, viz., On the Growth and Management of Eucalyptus Plantations and their Economic Uses, and On the Comparative Advantages of the various Methods of Producing and Harvesting Cinchona Bark, with Specimens. Reports and collections must be forwarded to the Secretary on or before June 14, 1884.

* * *

In a recent editorial article in the *Medical Times and Gazette*, on "The Place of Botany in the Curriculum," the belief is expressed that botany, instead of being as heretofore the landmark of materia medica, will rise to be one of the widest and most all-embracing subjects of the medical course. But in order for this to be the case, plants must be studied as illustrations of a special aspect of life, and the physical and physiological laws underlying the phenomena of plant nutrition, of tension of tissues, and the mechanics of growth, must be learned and understood. A knowledge of the life history and conditions of development of the various bacilli and other minute organisms, a comparison of the parasitic diseases of plants and animals and the conditions conducive to their development, and a knowledge of the abnormal growths of plants, are other subjects which will doubtless in the future crowd out a great deal of the systematic and morphological botany which has hitherto had a primary place in botanical lectures in medical schools. A practical acquaintance with the use of the microscope, section cutter, and of dyes for vegetable tissues will probably form a *sine quâ non* for the medical student of the future.

* * *

According to a return by Mr. Consul-General Ross, the quantity of Persian opium exported from the port of Bushire during the year 1882, was 4512 chests, of which rather over a thousand chests came to London and nearly the whole of the remainder went to Hong Kong. Another 2000 chests were shipped for China from Bunder Abbass.

We notice in a recent issue of the *Lancet* an appeal from Mr. J. Fayle, of Prospect Hill, Walthamstow, to old Guy's Hospital men who attended William Allen's lectures on chemistry and experimental philosophy to give him any assistance they can, in the shape of memoranda or reminiscences, in writing "a popular, and as far as possible original sketch of a man of whom England may be proud, but who is now little appreciated." As William Allen was the first President of the Pharmaceutical Society of Great Britain we may be excused for expressing a hope that Mr. Fayle may successfully carry out his intention and produce a book worthy of the subject.

The *American Druggist* states that the Chemical Laboratory of the John Hopkins University, which has just been opened, measures one hundred feet by fifty feet, and has three stories and a basement. It is under the charge of Professor Remsen.

Transactions of the Pharmaceutical Society.

NORTH BRITISH BRANCH.

EVENING MEETING.

The second meeting of the present session was held in the Society's Rooms, 119A, George Street, Edinburgh, on Wednesday, December 19, at half-past eight o'clock. Mr. John Nesbit, President of the Branch, in the chair.

The minutes of the previous meeting having been read and confirmed, the Secretary to the Branch announced the following donations:—

To the Museum:—

Specimen of colocynth fruit.

From Mr. JAMES MACKENZIE.

Specimen of ol. rusci verum.

From Mr. THOMAS GREENISH.

Specimens of baycuru, guaco, tayuyu, jaborandi, pao pereira, cascara sagrada, *Euphorbia pilulifera*, *Berberis aquifolia*, buckeye bark, gum angico, yerba santa, corn silk and damiana.

From Dr. SYMES.

Mr. MacEwan, in calling attention to these specimens, said that several of them, though now in common use, had previously been unrepresented in the Branch Museum. The specimen of Russian birch tar oil, sent by Mr. Greenish, differed considerably from the commercial variety, a specimen of which was also on the table, and which he believed was prepared in Germany. The most marked points of difference were in the odour, the Russian being pleasanter than the German, and in the amount of volatile constituents. The Russian variety lost about 20 per cent. under the boiling point of water, while the German lost three times as much; the former had thus more body than the latter, and was quite suitable for currying, whereas other varieties which he had met with were not. There were other interesting features about the oils which could not be referred to briefly. Several of the drugs which Dr. Symes had sent had not previously been shown at the meetings, and of these the Brazilian drugs were worthy of note. Dr. Symes took a lively interest in the materia medica of Brazil, and much of the information regarding the specimens shown was the result of his investigations. Gum angico, known in Brazil as *Resin de Angico*, was obtained from *Acacia Angico*. It appeared from Dr. Symes's investigation that one-half of this gum was soluble in water, the other half being soluble on the addition of an alkali; probably a low percentage of ash might account for this sparing solubility. In Brazil a mucilage of the gum was used for pectoral affections. The specimen of pao pereira was the inner bark of *Geissospermum Vellosii*, an Apocynaceous plant, which, like many others of that order, was reputed to possess powerful febrifuge properties. Tayuyu, the root of *Trianosperma ficifolia*, would interest students, owing to its large spiral vessels, which could be seen with the naked eye. Medicinally the root was used in scrofulous affections. The large russet-brown root shown was a specimen of baycuru, which resembled somewhat a root official in the last United States Pharmacopœia and obtained from *Statice Caroliniana* (marsh rosemary). Mr. Holmes believed that baycuru was also obtained from a species of *Statice*, probably *Statice Brasiliensis*. Its distinctive characteristic appeared to be the ray of light-coloured vascular tissue situated towards the circumference; this ray was compact in the smaller roots, but in the larger was disintegrated, owing probably to more rapid growth of the surrounding tissue. In Brazil it was highly esteemed as a remedy for glandular swellings and sore throat, its medicinal properties being due, no doubt, to the variety of tannin which it contained. The other specimens he would be glad to describe after the meeting.

The President of the Branch moved a hearty vote of thanks to the donors, and remarked that it was of great importance to have an acquaintance with the various new remedies which are brought under the notice of the medical profession, and the Branch owed a debt to those gentlemen who had sent the interesting collection. He then called upon Mr. Maben to read a paper on—

THE SOLUBILITY OF CALCIC HYDRATE IN WATER AT DIFFERENT TEMPERATURES.

The paper is printed on p. 505, and gave rise to the following discussion:—

Mr. Dott, in moving a vote of thanks to the author of the paper, said that an eminent scientist had remarked that one could not open a text-book without finding a subject for investigation. The paper which had been read was an illustration of the truth of this statement, and he felt that those present were indebted to Mr. Maben for the interesting manner in which he had brought the results of his investigation before them. The solubilities stated were somewhat lower than his experience had led him to expect, and he had thought that something like 1 in 721 at normal temperatures represented a saturated solution. He had little to say regarding the method which Mr. Maben had adopted, but he might point out that before measuring at any given temperature the solution should be kept for some time at that temperature in order to ensure accuracy.

Mr. Stephenson seconded the motion and remarked that there was one source of weak lime water which had not been referred to. Some were in the habit of putting a quantity of lime into a jar and filling the jar with water from time to time until scarcely anything but chalk was left, the lime water being, consequently, much too weak. A fresh quantity of lime should be used each time according to the official process, and if anyone tasted the water before placing the bottle on the shelf, a fair indication of its value would be got.

The President heartily concurred with the remarks which had fallen from the previous speakers. He recollected that Mr. Abraham had attributed deficiency of lime in part to the presence of sodium chloride in the limestone used, and asked Mr. Maben if he had found this to be the case.

Mr. Maben said that he had only used pure calcium oxide in his experiments; these had been done at different times with similar results, and the figures given he had endeavoured to corroborate fully. His experience of the use of limestone was corroborative of Mr. Abraham's observation, and he mentioned that Mr. Abraham's recommendation to wash the lime before using it was a capital method for removing this source of weakness.

The President then called upon Dr. Macadam to communicate a report on—

SALICYLATE OF SODA.

In the course of his remarks, Dr. Macadam stated that he had recently had occasion to examine some "salicylate" of soda powders from which fatal results had arisen, and he thought that it would interest the meeting to know how he had gone about the investigation which he had made. After describing the preparation of salicylic acid from oil of wintergreen, salicin and carbolic acid, he stated its uses as a thereapeutic agent and preservative. It was now well known that many articles of food, such as milk and beer, were kept sweet by salicylic acid, and the French, alive to the importance of all such articles, had permitted its use in preserving wine. The quantity admitted in this case was something like 0·15 gram per litre. This quantity, though small, was quite capable of detection, and he proceeded to illustrate the delicate ferric chloride test, using a solution containing one grain per gallon. The detection of salicylic acid in milk was then shown, the lecturer explaining that dialysis was the best means of obtaining from milk a clear solution of the preservative; this could be done by placing over a beakerful of water a piece of parchment paper, which should dip into the liquid and should be secured with an indiarubber band. The milk is placed in the paper and after a short time, the contents of the beaker will be found to give a beautiful violet colour with perchloride of iron. The method was also illustrated with a small dialyser. After explaining dialysis, he concluded with an account of the examination of the salicylate of soda powders already referred to, which he found to contain 52 per cent. of muriate of morphia.

Mr. Mackenzie said that there could be but one opinion regarding the interesting manner in which Dr. Macadam had brought his subject before the meeting. The case which had been referred to was certainly a very painful one, and it was to be regretted that the origin of the mistake had not been traced. It was important that all connected wlth pharmacy should be able to apply such tests as Dr. Macadam had shown, and he had much pleasure in moving a vote of thanks to the lecturer.

Mr. Dott, in seconding the motion, said that he was surprised that the medical man did not taste the powders containing morphia; they were quite bitter, and this fact might have led him to suspect that death was not due to salicylate of soda. Reference had been made to the estimation of morphia by means of intensity of colour reactions; this he did not think reliable, and a standard solution of biniodide of mercury might be used with preference.

After a few words from Dr. Macadam, in which he stated that the morphia was estimated gravimetrically, the President called upon Mr. Boa to read a paper on—

Hippurate of Soda.

The paper is printed on p. 506.

On the motion of Mr. Maben, a vote of thanks was awarded, and a short discussion took place, in the course of which Mr. Boa stated that it seemed to be generally understood that carbonate of lithia is insoluble in water, but he found that 5 grains could be dissolved in an ounce of distilled water with the aid of a little heat. In reply to a remark from Mr. Mackenzie he said that he had not tried the effect of extract of liquorice in covering the taste of the hippurate, but he thought that it would give good results.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The fifth general meeting of the thirty-fifth session was held at the Royal Institution, on Thursday evening, December 6.

In the unavoidable absence of the President, Mr. Edward Davies, the chair was taken at the request of the meeting by Mr. Michael Conroy.

The minutes of the previous meeting were read and confirmed, and the following donations were announced:—'The Proceedings of the Liverpool Architectural Society,' from the Society; 'Annual Report of the Liverpool Geological Association,' from the Association; and the *Pharmaceutical Journal*, from the Society.

Mr. H. O. Dutton exhibited a specimen of ensilage taken from one of Lord Tollemache's silos. The ensilage had been taken from the silo about fourteen days previously, and was quite as damp and as good as on the day it was cut out. Lord Tollemache, Mr. Dutton said, used 2lb. of salt to the hundredweight of freshly mown grass when placed in the silo, and supposing only 14lbs. of the ensilage was given daily to each animal, this would be equivalent to about a quarter of a pound of salt per day. He thought such a quantity would very likely cause diarrhœa, if animals were regularly fed on it. Mr. Dutton mentioned that he had seen some of the ensilage given to three cows, and would testify to the readiness with which it was eaten by them. The question was whether it was necessary to use so much salt.

In reply to Mr. Conroy, Mr. Dutton said that the grass was cut early in the morning, and was carted with the dew upon it.

The thanks of the meeting were accorded to Mr. Dutton for his interesting communication.

A paper was then read, entitled—

Note on the Estimation of Fixed Oils and Fats with Special Reference to Milk.

BY A. C. ABRAHAM, F.C.S,

The plan generally followed for the estimation of fixed oils in such things as linseed meal has generally been maceration and percolation, or the latter alone with ether, benzol, or some similar solvent. Anyone who has followed either course will, I think, readily admit the troublesomeness of it and the great care involved in preventing loss, especially when dealing with small quantities. To obviate these difficulties, I adopted a year or two ago for linseed meal the following plan, which I have since used for other substances and which I believe to be more accurate as it certainly is more easy than those generally followed. The principle is simply that of macerating the substance to be estimated in the suitable solvent, taking half or a known proportion of the *total liquid resulting*, finding the amount of fat in it and calculating therefrom the amount in the whole.

To take linseed meal (or more correctly, crushed linseed, *i.e.*, the linseed crushed but not deprived of its oil) as an example. My procedure is as follows:—A tube is taken of about 1 inch in diameter and 14 inches in length, contracted at the neck and stoppered; in it is placed 100 grains of linseed meal and upon this is poured 2000 fluid grains of spirit of wine less such an amount as will approximately represent the volume of the oil contained in a genuine and fair quality sample of the meal. The tube is now shaken to enable the spirit to expel all the air from the meal and when this has taken place the tube is graduated at the point at which the liquid stands. It is now ready for use. When it is desired to estimate a sample, 100 grains of the meal are inserted and ether added until it reaches the mark; it is then stoppered or corked and occasionally shaken during a sufficient time, when, if any loss has taken place by evaporation, or the volume has been apparently diminished by the loss of air from the meal, it is made up to the original point, again shaken and set aside. When it has completely subsided, 1000 fluid grains of the clear supernatant liquid are removed with a pipette, evaporated and weighed as usual. By doubling the product so obtained, the amount of oil, together with such other matters contained in the meal as are soluble in ether, is arrived at.

It will be readily admitted, I think, that if the amount of matter soluble in ether were known before the estimation was commenced this process would be unexceptionable. I believe, however, that the error admitted by the want of this knowledge will upon consideration appear so trifling, even for an article containing so much oil as does linseed meal, as to be perfectly unimportant. Suppose, for instance, that the meal contains 20·2 per cent. of oil, etc., which we may assume to increase the bulk of the resulting solution to the extent of 20 fluid grs., now if no allowance at all were made for this the bulk of the solution would be 2020 fluid grs. instead of 2000 which is required. If only 1000 of this were taken, that portion would be less than the remainder by 20 fluid grs., *i.e.*, to say supposing the 1000 fluid grs. taken were found to contain 10 grs. of oil, the remaining portion would contain 10·2 grs., and by doubling the former amount we should get a result of 20 instead of 20·2 an error of one-hundredth of the product or ·2 per cent., which if considered important can be neutralized by an allowance at the end of the operation. Or, if thought preferable, 2000 fluid grs. of the solvent may be always used and an allowance made in proportion to the result found.

In this process it is assumed that all the solvent is capable of dissolving all of the matter to be dissolved and that none of the latter will remain in a fixed condition in or upon the tissues of the article containing it. Whether this assumption be absolutely true or not, I think it will be admitted that if it is not, no process of percolation is likely to obviate it. In regard to milk the case is somewhat different, because to follow the process it is essential to evaporate the milk with either hydrated sulphate of calcium or powdered glass; the latter perhaps preferable on theoretical grounds, but the former what I have generally myself used.

The details of the process as applied to milk are as follows:—

A 1000 gr. specific gravity bottle is filled with the milk, the weight taken which gives the specific gravity. This is emptied upon 250 grs. of powdered glass or hydrated sulphate of calcium, and the flask either weighed or rinsed out with a few drops of distilled water, although practically neither is necessary as the amount of milk adhering to the flask when once found will be practically constant for all samples (unless sour). The milk taken is to be evaporated to dryness with the glass and thoroughly powdered, when it is to be introduced into a tube; 2000 fluid grs. of ether added from a pipette, so as to avoid loss by evaporation; the tube stoppered, shaken occasionally during some hours, after which 1000 fluid grs. may be removed, dried and weighed. This must not simply be doubled, as an allowance must be made for the fat dissolved by adding to the weight found $\frac{1}{9}$ (the specific gravity of butter fat being about ·900), deducting this from 1000 and calculating the whole amount present by a simple proportion, thus—

Fat found, say	9
Add $\frac{1}{9}$	1
	10

∴ 990 fluid gr. of ether took up 9 grs. of fat, how much would 2000 take up?

$$990 : 2000 :: 9$$
$$11 \mid 200$$
$$18{\cdot}18 \quad \text{Total fat present.}$$

The difference between the amount which would be arrived at by simply doubling the weight found and that obtained as above will never amount to more than about ·005 per cent.

For this process of estimation it would be clearly much better, if possible, to extract the fat from the milk whilst still in a liquid condition, and if this could be done by simply boiling the milk down in a graduated tube, then adding the ether, making it up so that the ethereal solution should measure a convenient quantity, and drawing off half of this with a pipette, it would be much better; but I have not had time to try whether this can be done, although I believe it might.

There is another process which I have to mention, one which has been even less tried than the one I have named, for, although it has suggested itself to my mind some time, I have not tried it until within the last ten days. It is applicable to all emulsions, such as milk, and, as far as I have gone yet, may be described as follows:—

A piece of Parker's paper fibre lint, 4 inches by 2, is made into a roll, a piece of thin wire is passed through the centre, wound once or twice round the roll, and fixed into the stopper of a suitable weighing bottle in such a manner that the roll may be sufficiently far from the sides to enable it to be lifted in or out without any fear of touching the sides. The roll is then taken out of the bottle and dried in a water-oven with the bottle until its weight is constant, 5 c.c. of milk are then dropped upon it from a pipette, when the stopper with the roll attached is re-inserted in the bottle and the whole weighed. The stopper is then removed and with its attachment placed in a drying oven with the bottle and kept there until it ceases to lose weight.

The excess of weight over the original weight gives the total solids. The stopper and roll are now removed and placed in another similar bottle—preferably ground to fit the same stopper as the first—sufficient ether added so that the roll may be covered (about 50 c.c. is a convenient quantity) and allowed to macerate some hours; it is then transferred to another similar bottle, and again to a third, after which the fat will be found to have been entirely extracted.* It is now removed and again weighed as before; the loss is fat.

If desired the fat may be weighed directly by evaporation of the ethereal liquids, or the tubes in which they are contained may be graduated, the volume made up to the graduation, the liquid stirred with a pipette and half or a known proportion drawn off from each. The latter method I think in some respects preferable, as it does not involve the removal of the liquid from one vessel to another, which, if done, introduces an element of uncertainty, owing to the adhesion of a certain amount of the fluid to the vessel from which it is poured, and also involves the washing of the vessels to obviate the last-mentioned difficulty. It will be noticed that I have made no reference hitherto to the estimation of the ash, and this is because I have thought it impossible to expect anything like a small or possibly even a constant ash from an article not specially made for analytical purposes. I am not without hopes, however, that by means of washing with acids, even Parker's paper fibre lint may be so freed from ash as to enable the whole four determinations of total solids, solids not fat, fat, and ash to be made with very great accuracy from the one small sample of milk. The sugar may also be estimated by immersion in water, but great care is required to prevent portions of the lint from falling off.

If, however, this cannot be done I do not think that it renders valueless the whole process, because at the worst the ash can be easily estimated as hitherto; and, moreover, I do not see why a special preparation, such as mononitrocellulose, dinitrocellulose, or some other body which would be sufficiently absorbent and yet leave no ash on incineration, might not be found or specially made for the purpose. I have only made one estimation of milk by this process and this with rather unsuitable and improvised apparatus, but I subjoin the results, which seem clearly to show that it is capable with experience of producing very accurate results, and in some respects more accurate than the processes generally followed.

The estimation No. 1 was made, as far as total solids are concerned, in the ordinary manner, but the solids not fat were estimated by difference, which is by no means an accepted method. The conclusions that I would draw from the figures are that the total solids can be estimated with much greater accuracy than by the ordinary method and in shorter time; and that it is impossible to dry the fat completely at a temperature of 212°. Dr. James Bell, the principal of the Somerset House Laboratory, says in his recent work upon 'The Analysis and Adulteration of Foods,' according to the *Analyst*, in the first place, that the determination of total solids is a comparatively easy operation, but later on that it is difficult to get a constant weight for the total solids, and that, therefore, the items, solids not fat and fat *are generally more satisfactory*, which as I understand it, means that the total solids are *very difficult indeed* to obtain by direct estimation.

* It is important that the lint should not be too near the bottom, because the fatty solution which can be seen falling from it should have room to collect below.

The total solids in column No. 1 were dried until the weight appeared to be constant (using the quantity and apparatus recommended by Dr. Bell) at 212°, and yet they stand very much higher than those in column 2, which were estimated until of constant weight on the paper fibre lint.

Dr. Bell recommends the drying of the fat in a water-oven, and, therefore, presumably at 212°; and it will be seen that the results arrived at (see columns 1 and 3, which were both obtained by direct weighing), after drying at this temperature, very closely agree, but that the weight lost by immersion of the lint in ether is more than ·10 less. In other words the fat lost was ·11 less than the same fat when dried at 212°. This I think at least shows that 212° is *not* sufficient to dry the fat. I think that if I were a milkman I should be disposed very much to question a method of analysis which does not enable the analyst to rely upon his estimation of total solids, but compels him to fall back upon his weighing of solids, not fat and fat, both of which weights are arrived at after manipulation, which may entail a loss.

With regard to the drying of the fat I have not tried whether a temperature of 220° would enable an accurate weighing to be made, and with regard to the total solids, I do not think it would be right to apply so high a temperature, because we do not know exactly what effect it may have upon the constituents of milk.

	No. 1.	By difference. No. 2.	By direct weighing. No. 3.
Total solids	11·97	11·38	—
Solids not fat (by difference only)	8·95	8·48	—
Fat	3·02	2·90	3·01

In conclusion, I should say that in the one experiment which I have made, the time occupied was certainly rather long; but I believe that this was due to the fact that the roll was rather tight and an ordinary drying oven was used, whereas a tabular oven which would allow a constant and rapid circulation of air around and through the roll would probably have produced results comparable in point of time with those attained by other means.

Mr. H. O. Dutton, in proposing a vote of thanks to Mr. Abraham, said he found the results of analysis of samples of genuine milk very variable, and gave the subjoined analysis of three samples from three cows, the samples being all taken at the same time, and the cows having been fed for some days previously on the same kind and quantity of food exactly.

In 100 c.c. of the sample.

Sample.	Sp. gr.	No of grams of total solids.	No. of grams of fat.	No. of grams. of solids not fat.
1	1·0325	10·80	2·04	8·76
2	1·0270	12·74	4·59	8·15
3	1·0340	13·60	3·80	9·80

Mr. Dutton also showed how the quality of pure milk varies at different seasons of the year, and submitted the following table showing the quantity of cheese produced from 100 gallons of pure milk, at four different times in the year, taken from the daily record kept in the diary of the same farm.

Yield of milk in gallons.	Quantity of cheese weighed after six days from 100 galls. milk.	Date of making.
311	105·83 lb.	May 23
279	98·20 lb.	July 11
180	121 lb.	Sept. 24
150	132·33 lb.	Nov. 11

Showing that, while in summer, the cows produce more than twice as much milk, that milk is not nearly so rich in cheese as during the winter months, when fed upon artificial fodder. These facts, he thought, tended to prove how very easily a perfectly innocent dealer might get an evil reputation.

Dr. Symes, in seconding the vote of thanks to Mr. Abraham, said he considered the paper of much value, and the new method of estimation a marked improvement.

Mr. Conroy, thought the method of drying an ingenious one, and having put the motion from the chair, it was carried by acclamation.

Proceedings of Scientific Societies.

CHEMICAL SOCIETY.

A meeting of this Society was held on Thursday, December 20. Dr. W. H. Perkin, F.R.S., President, in the chair.

The following gentlemen were declared by the Scrutators (Messrs. Meldola and Williams) duly elected Fellows of the Society:—Messrs. W. P. Bloxam, A. Cobb, G. C. Chambers, A. E. Ekins, F. P. Haviland, F. Keeling, W. H. R. Kerry, J. J. Pilley, M. Percy, J. Phillips, A. W. Rogers, W. J. Saint, G. Smith, A. Smithells.

The following certificates were read for the first time:—J. H. Burland, R. A. Bush, T. R. Duggan, G. W. Gibson, F. W. Harris, C. W. Sutton, F. W. Tompson, E. W. Voelcker.

The President then called on Mr. C. O'Sullivan to read a paper, entitled—

Researches on the Gums of the Arabin Group. Part I. Arabic Acid: its Composition and the Products of its Decomposition.—The author, wishing to compare arabic acid with other bodies with which he was working, looked up the literature of the subject, but found the results obtained by previous observers so irreconcilable that he was forced to examine this substance for himself. The present paper contains the first results of this examination. The author has mainly followed the method employed by Neubauer. The gum is dissolved in the smallest possible quantity of water, and the solution decanted from any insoluble matter; twice or three times as much hydrochloric acid as is sufficient to convert the bases into chlorides is added, and the arabic acid then precipitated by an excess of alcohol. The curdy precipitate is washed with alcohol and pressed; it is then dissolved in boiling water, cooled, and alcohol gradually added with constant stirring. The liquid becomes milky, but no precipitate forms; a few drops of hydrochloric acid are added, when a curdy precipitate is produced. By the careful addition of hydrochloric acid the body can be precipitated in several successive portions. The author obtained four such precipitates; each portion was redissolved and reprecipitated several times, dehydrated with absolute alcohol, pressed, and dried over sulphuric acid. Thus treated the bodies are white, friable, soluble in water, and free from ash. By an optical examination, and the analysis of their barium salts, the author proved that he was dealing with a homogeneous body, the optical activities ranging from $[\alpha]j - 25·7$ to $-27·0$, and the percentage of barium oxide from 5·90 to 6·07. It occurred to the author that a careful study of the action of sulphuric acid might throw some light on the nature and composition of arabic acid, and that this body should yield a sugar or sugars and a series of acids of gradually diminishing molecular weight; in fact, that it would behave after the manner of starch (*Chem. Soc. Journ.*, 1876, ii., 125). Five hundred grams of arabic acid $[\alpha]j - 27°$, which must be free from ash, were dissolved to 1500 c.c., and 40 grams of sulphuric acid in 150 c.c. of water added. The mixture was boiled for three hours, cooled and exactly neutralized with a hot solution of barium hydrate. The barium sulphate filtered off, the filtrate evaporated to 1000 c.c., and alcohol specific gravity ·83 added as long as a precipitate fell. This waxy precipitate was repeatedly dissolved in water, reprecipitated by alcohol to free it from sugar and dried over sulphuric acid. This white friable body when dried at 100° gave 14·57 BaO. The arabic acid molecule had, therefore, broken up. It remained to be proved whether the substance was homogeneous or not. It was dissolved in water and fractionally decomposed by successive additions of sulphuric acid, into three portions, A, B and C. A contained 14·27 per cent. BaO. B, 14·35 per cent. C, 15·46 per cent. Portion C was further separated into three: the 1st contained 15·27 BaO; 2nd 15·36 per cent.; 3rd 15·54 per cent.: it was, therefore, fairly homogeneous. A and B were mixed, and on fractionation it became evident that there were two salts, one containing 13·3 to 13·4 per cent. BaO, the other 15·5 per cent. BaO. The author then studies the further action of sulphuric acid on this 15·5 per cent. barium salt. Twenty grams were dissolved in water, and 2·5 c.c. of sulphuric acid previously diluted with water added, the mixture was digested for three hours at 100°; by neutralization and treatment as above a salt was obtained containing 18·5 per cent. BaO. This salt was submitted to combustion, it gave numbers indicating the formula $C_{23}H_{38}O_{22}BaO$; it is therefore not a carbohydrate, but differs from the carbohydrate $C_{24}H_{40}O_{20}$ by the subtraction of CH_2 and addition of O_2. The alcoholic solution from which this salt had been separated was freed from alcohol, the residue concentrated to a syrup, purified and allowed to crystallize, when a sugar of the class $C_6H_{12}O_6$ separated out; its optical activity was $[\alpha]j$ 79°–81° and copper reducing power $K = 81-82$. The salt containing 15·5 per cent. BaO was next dried and analysed; it gave a formula $C_{29}H_{48}O_{27}BaO$. The 18·5 per cent. BaO salt was doubtless, therefore, derived as follows:—

$$C_{29}H_{48}O_{27}BaO + H_2O = C_{23}H_{38}O_{22}BaO + \underset{\alpha\ \text{arabinose}}{C_6H_{12}O_6}$$

The 13·3 barium salt corresponds to the formula—$C_{35}H_{58}O_{32}BaO$, so that we have the series —

$$C_{23}H_{38}O_{22}BaO + C_6H_{10}O_5 = C_{29}H_{48}O_{27}BaO$$
$$C_{29}H_{48}O_{27}BaO + C_6H_{10}O_5 = C_{35}H_{58}O_{32}BaO$$

The high molecule being broken down with elimination of $C_6H_{10}O_5$, which is hydrated to a sugar of the $C_6H_{12}O_6$ class, it appeared probable that the arabic acid molecule was broken down in the same way and that its composition would be arrived at by adding such a multiple of $C_6H_{10}O_5$ to one of these barium salts as would give a compound containing the same quantity of BaO as barium arabate. To obtain further evidence of this disintegrating process 200 grams of pure arabic acid $[\alpha]j$—27° were dissolved in 300 c.c. of water, to which 10 grams of sulphuric acid were added and the whole was digested at 100° for one hour. The product was separated as before by fractional precipitation and eventually two salts obtained containing 11·35 per cent. BaO and 13·38 per cent. BaO. The latter was the salt already noticed $C_{35}H_{58}O_{32}BaO$. The 11·35 per cent. salt was analysed and gave a composition—$C_{41}H_{68}O_{37}BaO$

$$C_{41}H_{68}O_{37}BaO + H_2O = C_{35}H_{58}O_{32}BaO + C_6H_{12}O_6.$$

The free acid of this salt was also prepared; its analysis confirmed the above formula. At this point the author set to work to isolate the sugars which ought to be separated at the various steps of the disintegration of the molecule of arabic acid. Starting with the alcoholic solution from which the salt $C_{29}H_{48}O_{27}BaO$ had separated he succeeded in obtaining three sugars of the $C_6H_{12}O_6$ class, which he names β-arabinose $\alpha j = 111·1°$ K 110; γ-arabinose, $\alpha j = 91°$ K $= 99·4$—100; and δ-arabinose $\alpha j =$ 79°—81° K 81—82, and in proving the presence of α-arabinose with a greater optical activity than β-arabinose. The author then gives the results of six analyses of arabic acid; the numbers lead to the empirical formula $C_6H_{10}O_5$. Now a barium salt containing CHO in this ratio and at the same time 6 per cent. BaO should be $C_{90}H_{150}O_{75}BaO$, but such a constitution does not lead to the highest acid $C_{41}H_{68}O_{37}$ obtained in the decomposition products, thus $C_{41}H_{68}O_{37} + 8\,C_6H_{10}O_5 = C_{89}H_{148}O_{77}$, but writing the equation thus

$$C_{41}H_{68}O_{37} + 8\,C_6H_{10}O_5 = C_{89}H_{142}O_{74} + 3\,H_2O$$

we obtain a formula for arabic acid $C_{89}H_{142}O_{74}$ which fits exactly with the combustion percentages and requires 6 per cent. BaO, the numbers obtained being 6·10, 5·90, 6·00, 6·16. The calcium salt was prepared and gave similar results. Arabic acid may therefore be represented by $C_{89}H_{142}O_{74}$. Finally the author made a successful attempt to isolate the acids intermediate between arabic acid and the $C_{41}H_{68}O_{37}$ acid. Sixty grams of pure arabic acid were dissolved in 200 c.c. of water containing 4 grams of sulphuric acid and digested for fifteen minutes at 100° C. Two barium salts were obtained, containing 6·45 per cent. BaO and 7·36 per cent., corresponding respectively to $C_{83}H_{132}O_{69}BaO$ and $C_{71}H_{112}O_{53}BaO$: β-arabinose αj 111·5° K 110 was also isolated and evidence obtained that α-arabinose αj 140° was present. Neither γ- nor δ-arabinose was detected. The author then gives a summary of this most important paper respecting the decompositions of arabic acid by sulphuric acid.

$$\text{I.}\quad \underset{\text{Arabic acid.}}{C_{89}H_{142}O_{74}} + H_2O = \underset{\alpha\text{-arabinosic acid.}}{C_{83}H_{132}O_{69}} + \underset{\alpha\text{-arabinose}}{C_6H_{12}O_6}$$

$$\text{II.}\quad C_{83}H_{132}O_{69} + H_2O = \underset{\beta\text{-arabinosic acid.}}{C_{77}H_{122}O_{64}} + \underset{\alpha+\beta\text{-arabinose.}}{C_6H_{12}O_6}$$

$$\text{III.}\quad C_{77}H_{122}O_{64} + H_2O = \underset{\gamma\text{-arabinosic acid.}}{C_{71}H_{112}O_{59}} + \underset{\beta\text{-arabinose.}}{C_6H_{12}O_6}$$

The next five steps have not been followed and so are united.

$$\text{III.—VIII.}\quad C_{77}H_{122}O_{64} + 9\,H_2O = \underset{\alpha\text{-arabinosic acid.}}{C_{41}H_{68}O_{37}} + \underset{\beta,\ \gamma,\ \delta,\ \text{and other arabinoses.}}{6\,C_6H_{12}O_6}$$

$$\text{IX.}\quad C_{41}H_{68}O_{37} + H_2O = \underset{\iota\text{-arabinosic acid.}}{C_{35}H_{58}O_{32}} + \underset{\delta\text{-arabinose (?).}}{C_6H_{12}O_6}$$

$$\text{X.}\quad C_{35}H_{58}O_{32} + H_2O = \underset{\kappa\text{-arabinosic acid.}}{C_{29}H_{48}O_{27}} + \underset{\delta\text{-arabinose (?).}}{C_6H_{12}O_6}$$

$$\text{XI.}\quad C_{29}H_{48}O_{27} + H_2O = \underset{\lambda\text{-arabinosic acid.}}{C_{23}H_{38}O_{22}} + \underset{\delta\text{-arabinose.}}{C_6H_{12}O_6}$$

This last arabinosic acid, $C_{23}H_{38}O_{22}$, is a very stable body, resisting the action of 3 per cent. to 4 per cent solution of sulphuric acid for many hours. It probably splits up in a more complicated way than its predecessors. Arabic acid, αj—27° to —28°, is the chief constituent of all the lævorotatory gums; other acids are present, which bear a simple relation to it. In a future paper the author promises an account of the dextrorotatory and optically inactive gums, the acids of which are built up in the same manner as arabic acid.

Dr. Armstrong said the paper was one of the utmost importance, and was the more interesting as it had been read by the investigator who first enlightened chemists as to the constitution of starch in 1876. He then contrasted the results of the present paper with those obtained in the case of starch, and pointed out the probability that starch has a very high molecular weight.

Dr. Ramsay then read a paper entitled—

The Decomposition of Ammonia by Heat. By W. Ramsay and S. Young.—The results obtained may be summed up as follows:—When ammonia gas is passed through a porcelain tube, or an iron tube, or a glass tube, filled with asbestos cardboard, the amount of decomposition at 500°–520° is nearly equal and very small. Ammonia, therefore, begins to decompose a little below 500°. In contact with a glass surface the temperature at which decomposition begins is much higher; the amount of decomposition depends on the rate of passage of the gas and on the nature of the surface. Thus ammonia is completely decomposed by passage through a plain iron tube heated to 780°. By passing ammonia through a glass tube containing iron wire at 760°, 76 per cent. of the ammonia was decomposed; with copper wire under similar conditions only 2 per cent. was decomposed.

Mr. Warington pointed out the importance of these results in connection with the now common practice of making soda lime combustions in iron tubes.

Professor Foster made some observations as to the bearing of these experiments on the quantity of ammonia obtained in the distillation of coal.

Dr. Ramsay then read a paper—

On the Halogen Compounds of Selenium. By F. P. Evans and W. Ramsay.—The authors first prepared the selenium monochloride, Se_2Cl_2, which splits up on distillation into selenium and selenium tetrachloride; the tetrachloride is insoluble, the monochloride soluble in carbon disulphide. The selenium dichloride could not be prepared. Selenium tetrachloride begins to decompose at 288°. The authors have also prepared selenium chlorotribromide and the bromotrichloride.

On the Preparation of Pure Chlorophyll. By D. A. Tschirch.—The author states that chlorophyll is very unstable, being decomposed by acids and alkalies. He has prepared it by reducing chlorophyllan (*Botan. Zeitung*, 1882, 533) with zinc dust. The chlorophyll so obtained gives a spectrum identical with that given by living leaves.

The Society then adjourned to January 17, 1884.

BRITISH PHARMACEUTICAL CONFERENCE.

A meeting of the Executive Committee was held at 17, Bloomsbury Square, on Wednesday, December 19, at 4 p.m.

Present—Mr. J. Williams, President, in the chair; Professor Attfield, Messrs. Atkins, Brady, Hills, Naylor, Southall and Taylor, Dr. Thresh, Mr. Ekin (Treasurer), and Messrs. Benger and Plowman (Honorary General Secretaries).

The minutes of the previous meeting were read and confirmed.

Letters of apology for non-attendance were read from Messrs. Bell, Groves, Radley, Reynolds, Schacht and Stephenson.

Professor Attfield, on behalf of the Sub-Committee appointed at the last meeting of the Executive Committee to undertake the distribution of copies of the two last presidential addresses to members of both Houses of Parliament, reported that arrangements had been completed and that the addresses were all enclosed in stamped envelopes and would be posted on the following day. He also reported that Messrs. Butler and Tanner had received orders from chemists and druggists in different parts of the United Kingdom for about ten thousand copies of the Southport address, and that these orders had been executed.

A letter was read from the printers stating that a few copies of the 1883 'Year Book' would be bound by the end of December, and that a sufficient number for general distribution to the members would be ready early in January.

Mr. Siebold was re-appointed Editor of the 'Year Book' for 1884.

The Honorary General Secretaries reported that since the last meeting of the Executive Committee the following gentlemen had signified their willingness to act as Honorary Colonial Secretaries for the undermentioned districts:—

For Bengal ....Mr. C. N. Kernot, Calcutta.
For South Australia ......Mr. J. Parker, Adelaide.
For West Indies............Mr. W. C. Ross, Port of Spain.

Acting on the authority which had been given to the President and themselves at the last meeting of the Committee they had written to these gentlemen informing them that their services would be accepted. These appointments were confirmed.

Mr. Plowman (Hon. Gen. Sec.) reported that he had paid a visit to Hastings and had had interviews with certain members of the Committee resident in that town. He had been very kindly received and felt sure that these gentlemen would exert themselves to the utmost to make the coming meeting a success, and would endeavour to fully carry out the wishes of the Executive Committee.

The subject of entertainment by Local Committees, which had been discussed on several previous occasions, was again brought forward and, after a long discussion, the following resolution was passed:—

"That in future the members attending the meetings of the Conference shall pay for the luncheons, etc., supplied to them during the business days of the meetings, and that if excursions be organized by the local members on the following days all railway or other fares shall be paid by the members attending those excursions."

Sixteen gentlemen were elected to membership.

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE.

Presidential Address to the Chemical Section.

BY J. H. GLADSTONE, PH.D., F.R.S., V.P.C.S.

A sectional address usually consists either of a review of the work done in the particular science during the past year, or of an exposition of some branch of that science to which the speaker has given more especial attention. I propose to follow the latter of these practices, and shall ask the indulgence of my brother chemists while I endeavour to place before them some thoughts on the subject of Elements.

Though theoretical and practical chemistry are now intertwined, with manifest advantage to each, they appear to have been far apart in their origin. Practical chemistry arose from the arts of life, the knowledge empirically and laboriously acquired by the miner and metallurgist, the potter and the glass-worker, the cook and the perfumer. Theoretical chemistry derived its origin from cosmogony. In the childhood of the human race the question was eagerly put, "By what process were all things made?" and some of the answers given started the doctrine of elements. The earliest documentary evidence of the idea is probably contained in the Shoo King, the most esteemed of the Chinese classics for its antiquity. It is an historical work, and comprises a document of still more venerable age, called 'The Great Plan with its Nine Divisions,' which purports to have been given by Heaven to the Great Yu, to teach him his royal duty and "the proper virtues of the various relations." Of course there are wide differences of opinion as to its date, but we can scarcely be wrong in considering it as older than Solomon's writings. The First Division of the Great Plan relates to the Five Elements. "The first is named water; the second, fire; the third, wood; the fourth, metal; the fifth, earth. The nature of water is to soak and descend; of fire, to blaze and ascend; of wood, to be crooked and to be straight; of metal, to obey and to change; while the virtue of the earth is seen in seed-sowing and ingathering. That which soaks and descends becomes salt; that which blazes and ascends becomes bitter; that which is crooked and straight becomes sour; that which obeys and changes becomes acrid; and from seed-sowing and ingathering comes sweetness."*

A similar idea of five elements was also common among the Indian races, and is stated by Professor Rodwell to have been in existence before the fifteenth century, B.C., but, though the number is the same, the elements themselves are not identical with those of the ancient Chinese classic; thus, in the Institutes of Menu, the "subtle ether" is spoken of as being the first created, from which, by transmutation, springs air, whence, by the operation of a change, rises light or fire; from this comes water, and from water is deposited earth. These five are curiously correlated with the five senses, and it is very evident that they are not looked upon as five independent material existences but as derived from one

* Quoted from the translation by the Rev. Dr. Legge. In that most obscure classic, the *Yi-King*, fire and water, wind and thunder, the ocean and the mountains, appear to be recognized as the elements.

another. This philosophy was accepted alike by Hindoos and Buddhists. It was largely extended over Asia, and found its way into Europe. It is best known to us in the writings of the Greeks. Among these people, however, the elements were reduced to four—fire, air, earth, and water—though Aristotle endeavoured to restore the "blue ether" to its position as the most subtle and divine of them all. It is true that the fifth element, or "quinta essentia," was frequently spoken of by the early chemists, though the idea attaching to it was somewhat changed, and the four elements continued to retain their place in popular apprehension, and still retain it even among many of the scholars who take degrees at our universities. The claim of wood to be considered an element seems never to have been recognized in the West, unless, indeed, we are to seek this origin for the choice of the word ὕλη to signify that original chaotic material out of which, according to Plato and his school, all things were created.* The idea also of a primal element, from which the others, and everything else, were originated, was common in Greece, the difficulty being to decide which of the four had the greatest claim to this honour. Thales, as is well known, in the sixth century B.C. affirmed that water was the first principle of things; but Anaxamenes afterwards looked upon air, Heraclytus upon fire, and Theracleides on earth, as the primal element. This notion of elements, however, was essentially distinct from our own. It was always associated with the idea of the genesis of matter rather than with its ultimate analysis, and the idea of *simple* as contrasted with *compound* bodies probably never entered into the thoughts of the contending philosophers.

The modern idea appears to have had a totally different origin, and we must again travel back to China. There, also in the sixth century B.C., the great philosopher Lao-tse was meditating on the mysteries of the world and the soul, and his disciples founded the religion of Taou. They were materialists; nevertheless they believed in a "finer essence," or spirit, that rises from matter, and may become a star; thus they held that the souls of the five elements, water, metal, fire, wood, and earth, arose and became the five planets. These speculations naturally led to a search after the sublimated essences of things, and the means by which this immortality might be secured. It seems that at the time of Tsin-she-hwang, the builder of the Great Wall, about two centuries before Christ, many romantic stories were current of immortal men inhabiting islands in the Pacific Ocean. It was supposed that in these magical islands was found the "herb of immortality" growing, and that it gave them exemption from the lot of common mortals. The emperor determined to go in search of these islands, but some untoward event always prevented him.†

Some two or three centuries after this a Taouist, named Weipahyang, wrote a remarkable book called 'The Uniting Bond.' It contains a great deal about the changes of the heavenly bodies, and the mutual relation of Heaven and men; and then the author proceeds to explain some transformations of silver and water. About elixir he tells us, "What is white when first obtained becomes red after manipulation on being formed into the elixir" ("tan," meaning red or elixir). "That substance, an inch in diameter, consists of the black and the white, that is, water and metal combined. It is older than heaven and earth. It is most honourable and excellent. Around it, like a wall, are the sides of the cauldron. It is closed up and sealed on every side, and carefully watched. The thoughts must be undisturbed, and the temper calm, and the hour of its perfection anxiously waited for. The false chemist passes through various operations in vain. He who is enlightened expels his evil passions, is delighted morning and night, forgets fame and wealth, comprehends the true objects of life, and gains supernatural powers. He cannot then be scorched by fire, nor drowned in water, etc., etc. . . . The cauldron is round like the full moon, and the stove beneath is shaped like the half-moon. The lead ore is symbolized by the White Tiger; and it, like metal amongst the elements, belongs to the West. Mercury resembles the sun, and forms itself into sparkling globes; it is symbolized by the Blue Dragon belonging to the East, and it is assigned to the element wood. Gold is imperishable. Fire does not injure its lustre. Like the sun and moon, it is unaffected by time. Therefore the elixir is called 'the Golden Elixir.' Life can be lengthened by eating the herb called Hu ma; how much more by taking the elixir, which is the essence of gold, the most imperishable of all things! The influence of the elixir, when partaken of, will extend to the four limbs; the countenance will become joyful; white hair will be turned black; new teeth will grow in the place of old ones, and age at once become youth. . . . Lead ore and mercury are the bases of the process by which the elixir is prepared; they are the hinge upon which the principles of light and darkness revolve."

This description suggests the idea that the elixir of the Taouists was the red sulphide of mercury—vermilion—for the preparation of which the Chinese are still famous. That Weipahyang believed in his own philosophy is testified by a writer named Ko-hung, who, about a century afterwards, wrote the lives of celebrated Taouists. He tells how the philosopher, after preparing the elixir, took it, with his disciples, into a wood, and gave it first to his dog, then took it himself, and was followed by one of his pupils. They all three died, but, it appears, rose to life again, and to immortality. This brilliant example did not remain without imitators; indeed, two emperors of the Tang family are said to have died from partaking of the elixir. This circumstance diminished its popularity, and alchemy ceased to be practised in the Celestial Empire.

At the beginning of the seventh century the doctrine of Lao-tse was in great favour at the Chinese court; learning was encouraged, and there was much enterprise. At the same time the disciples of Mahomed carried their arms and his doctrines over a large portion of Asia, and even to the Flowery Land. Throughout the eighth century there were frequent embassies between eastern and western Asia, wars with the Caliphs, and even a matrimonial alliance. We need not wonder, therefore, that the teachings of the Taouist alchemists penetrated westward to the Arabian philosophers. It was at this period that Yeber - Abou - Moussah - Djaferal - Sofé, commonly called Geber, a Sabæan of great knowledge, started what to the West was a new philosophy about the transmutation of metals, the Philosopher's Stone, and the Elixir of Life; and this teaching was couched in highly poetic language, mixed with astrology and accompanied by religious directions and rites. He held that all metals were composed of mercury, sulphur, and arsenic, in various proportions, and that the noblest metal could be procured only by a very lengthy purification. It was in the salts of gold and silver that he looked for the Universal Medicine. Geber himself was an experimental philosopher, and the belief in transmutation led to the acquirement of a considerable amount of chemical knowledge amongst the alchemists of Arabia and Europe. This gradually brought about a conviction that the three reputed elementary bodies, mercury, sulphur, and salt or

---

* Students of the Apocrypha will rember the expression in the Book of Wisdom, xi., 17, '*ἡ παντοδύναμος σοῦ χεὶρ καὶ κτίσασα τὸν κόσμον ἐξ ἀμόρφου ὕλης*' ('Thy Almighty hand, that made the world of matter without form'). The same book contains two allusions to the ordinary elements, vii., 17, and xix., 18 to 20. The word *στοιχεῖον* is used in the New Testament only in a general sense (2 Pet., iii., 10), or in its more popular meaning of the first steps in knowledge.

† Nearly all the statements relating to this Taouist alchemy are derived from the writings of the Rev. Joseph Edkins, of Pekin, and the matter is treated in greater detail in an article on the "Birth of Alchemy," in the *Argonaut*, vol. iii., p. 1.

acid, were not really the originators of all things. There was a transition period, during which the notion was itself suffering a transmutation. The idea became gradually clearer that all material bodies were made up of certain constituents, which could not be decomposed any further, and which, therefore, should be considered as elementary. The introduction of quantitative methods compelled the overthrow of mediæval chemistry, and led to the placing of the conception of simple and compound bodies upon the foundation of scientific fact. Lavoisier, perhaps, deserves the greatest credit in this matter, while the labours of the other great chemists of the eighteenth and the beginning of the nineteenth centuries were in a great measure directed to the analysis of every conceivable material, whether solid, liquid, or gaseous. These have resulted in the table of so-called elements, now nearly seventy in number, to which fresh additions are constantly being made.

Of this ever-growing list of elements not one has been resolved into simpler bodies for three-quarters of a century; and we, who are removed by two or three generations from the great builders of our science, are tempted to look upon these bodies as though they were really simple forms of matter, not only unresolved, but unresolvable. The notation we employ favours this view and stamps it upon our minds.

Is it, however, a fact that these reputed elements are really simple bodies? or, indeed, are they widely different in the nature of their constitution from those bodies which we know to be chemical compounds? Thus, to take a particular instance, are fluorine, chlorine, bromine, and iodine essentially distinct in their nature from the compound halogens, cyanogen, sulphocyanogen, ferricyanogen, etc.? Are the metals lithium, sodium, and potassium essentially distinct from such alkaline bases as ammonium, ethylamine, diethylamine, etc.? No philosophical chemist would probably venture to answer this question categorically with either "yes" or "no." Let us endeavour to approach it from three different points of attack—(1) the evidence of the spectroscope, (2) certain peculiarities of the atomic weights, and (3) specific refraction.

1. *The Spectroscope.*—It was at first hoped that the spectroscope might throw much light upon the nature of elements, and might reveal a common constituent in two or more of them; thus, for instance, it was conceivable that the spectrum line of bromine or iodine vapour might consist of the rays given by chlorine *plus* some others. All expectations of this kind have hitherto been disappointed; yet, on the other hand, it must not be supposed that such a result disproves the compound nature of elements, for as investigation proceeds it becomes more and more clear that the spectrum of a compound is not made up of the spectra of its component parts.

Again, the multiplicity of rays given out by some elements, when heated, in a gaseous condition, such as iron, has been supposed to indicate a more complex constitution than in the case of those metals, such as magnesium, which give a more simple spectrum. Yet it is perfectly conceivable that this may be due to a complexity of arrangement of atoms all of the same kind.

Again, we have changes of a spectrum at different temperatures; new rays appear, others disappear; or even there occurs the very remarkable change from a fluted spectrum to one of sharp lines at irregular intervals, or to certain recurring groups of lines. This, in all probability, does arise from some redistribution, but it may be a redistribution in a molecular grouping of atoms of the same kind, and not a dissociation or rearrangement of dissimilar atoms.

A stronger argument has been derived from the revelations of the spectroscope in regard to the luminous atmospheres of the sun. There we can watch the effect of heat enormously transcending that of our hottest furnaces, and of movements compared with which our hurricanes and whirlwinds are the gentlest of zephyrs. Mr. Lockyer, in studying the prismatic spectra of the luminous prominences or spots of the sun, has frequently observed that on certain days certain lines, say of the iron spectrum, are non-existent, and on other days certain other lines disappear, and that in almost endless variety; and he has also remarked that occasionally certain lines of the iron spectrum will be crooked or displaced, thus showing the vapour to be in very rapid motion, while others are straight, and therefore comparatively at rest. Now, as a gas cannot be both at rest and in motion at the same time and the same place, it seems very clear that the two sets of lines must originate in two distinct layers of atmosphere, one above the other, and Mr. Lockyer's conclusion is that the iron molecule was dissociated by heat, and that its different constituents, on account of their different volatility, or some other cause, had floated away from one another. This seems to me the easiest explanation of the phenomenon; and, as dissociation by heat is a very common occurrence, there is no *à priori* improbability about it. But we are not shut up to it, for the different layers of atmosphere are certainly at different temperatures, and most probably of different composition. If they are of different temperatures the variations of the spectrum may only be an extreme case of what must be acknowledged by everyone more or less—that bodies emit, or cease to emit, different rays as their temperature increases, and notably when they pass from the liquid to the gaseous condition. And again, if the composition of the two layers of atmosphere be different, we have lately learnt how profoundly the admixture of a foreign substance will sometimes modify a luminous spectrum.

2. *Peculiarities of Atomic Weights.*—At the meeting of this Association at Ipswich, in 1851, M. Dumas showed that in several cases analogous elements form groups of three, the middle one of which has an atomic weight intermediate between those of the first and third, and that many of its physical and chemical properties are intermediate also. During the discussion upon his paper, and subsequently,* attention was drawn to the fact that this is not confined to groups of three, but that there exist many series of analogous elements having atomic weights which differ by certain increments, and that these increments are, in most cases, multiples of 8. Thus we have lithium, 7; sodium, 23, *i.e.* $7+16$; potassium, 39, *i.e.* $7+(16\times 2)$; and the more recently discovered rubidium, 85, *i.e.* $7+(16\times 5)$ nearly; and cæsium, 133, *i.e.* $7+(16\times 8)$ nearly. This is closely analogous to what we find in organic chemistry, where there are series of analogous bodies playing the part of metals, such as hydrogen, methyl, ethyl, etc., differing by an increment which has the atomic weight 14, and which we know to be CH_2. Again, there are elements with atomic weights nearly the same or nearly multiples of one another, instances of which are to be found in the great platinum group and the great cerium group.† This suggests the analogy of isomeric and polymeric bodies. There is also this remarkable circumstance: the various members of such a group as either of those just mentioned are found together at certain spots on the surface of the globe, and scarcely anywhere else. The chemist may be reminded of how in the dry distillation of some organic body he has obtained a mixture of polymerized hydrocarbons, and may perhaps be excused if he speculates whether in the process of formation of the platinum or the cerium group, however and whenever it took place, the different elements had been made from one another and imperfectly polymerized.

But this is not the largest generalization in regard to the peculiarities of these atomic weights. Newlands showed that, by arranging the numbers in their order, the octaves presented remarkable similarities, and, on the

* *Phil. Mag.*, May, 1853.

† Another curious instance is the occurrence of nickel and cobalt in all meteoric irons, with occasionally chromium or manganese, the atomic weights and other properties of which are very similar.

same principle, Mendelieff constructed his well-known table. I may remind you that in this table the atomic weights are arranged in horizontal and vertical series, those in the vertical series differing from one another, as a rule, by the before-mentioned multiples of 8—namely 16, 16, 24, 24, 24, 24, 32, 32—the elements being generally analogous in their atomicity and in other chemical characters. Attached to the elements are figures, representing various physical properties, and these in the horizontal series appear as periodic functions of the atomic weights. The table is incomplete, especially in its lower portions, but, with all its imperfections and irregularities, there can be no doubt that it expresses a great truth of nature. Now, if we were to interpolate the compound bodies which act like elements—methyl, 15; ammonium, 18; cyanogen, 26—into Mendelieff's table, they would be utterly out of place, and would upset the order both of chemical analogy and of the periodicity of the physical properties.

3. *Specific Refraction.*—The specific refraction has been determined for a large majority of the elements, and is a very fundamental property, which belongs to them apparently in all their combinations, so long at least as the atomicity* is unchanged. If the figures representing this property be inserted into Mendelieff's table we find that in the vertical columns the figures almost invariably decrease as the atomic weights increase. If, however, we look along the horizontal columns or better still if we plot the figures in the table by which Lothair Meyer has shown graphically that the molecular volume is a periodic function of the atomic weights, we shall see that they arrange themselves in a series of curves similar to but not at all coincident with his. The observations are not so complete or accurate as those of the molecular volumes, but they seem sufficient to establish the fact, while the points of the curves would appear to be, not the alkaline metals, as in Meyer's diagram, but hydrogen, phosphorus and sulphur, titanium and vanadium, selenium, antimony. Now, if we were to insert the specific refractions of cyanogen, ammonium, and methyl into this table, we should again show that it was an intrusion of strangers not in harmony with the family of elements.

But there is another argument to be derived from the action of light. The refraction equivalent of a compound body is the sum of the refraction equivalents of its compounds; and, if there is anything known for certain in the whole subject, it is that the refraction equivalent of an organic compound advances by the same quantity (7·6) for every increment of CH_2. If, therefore, the increment between the different members of a group of analogous elements, such as the alkaline metals, be of the same character, we may expect to find that there is a regular increase of the refraction equivalent for each addition of 16. But this is utterly at variance with fact: thus, in the instance above quoted, the refraction equivalent of lithium being 3·8, that of sodium is 4·8, of potassium 8·1, of rubidium 14·0, and of cæsium about 13·7. Neither does the law obtain in those series in which the increment is not a multiple of 8, as in the case of the halogens, where the increment of atomic weight is 45, and the refraction equivalents are chlorine 9·9, bromine 15·3, and iodine 24·5.

The refraction equivalents of isomeric bodies are generally identical; and the refraction equivalents of polymeric bodies are in proportion to their atomic weights. Among the groups of analogous elements of the same, or nearly the same, atomic weight we do find certain analogies: thus cobalt and nickel are respectively 10·8 and 10·4, while iron and manganese are respectively 12·0 and 12·2. But, as far as observation has gone at present, we have reason to conclude that, if metals stand to one another in the ratio of 2 : 1 in atomic weight, their refraction equivalents are much nearer together than that; while, on the other hand, the equivalent of sulphur, instead of being the double of that of oxygen, is at least five times as great.

The general tendency of these arguments is evidently to show that the elementary radicals are essentially different from the compound radicals, though their chemical functions are similar.

There remains still the hypothesis that there is a "primordial element," from which the others are derived by transmutation. With the sages of Asia it was the "blue ether," with Thales water, with Dr. Prout hydrogen. The earlier views have passed away, and the claims of hydrogen are being fought out on the battlefield of atomic weights and their rigorous determination.

There does not appear to be any argument which is fatal to the idea that two or more of our supposed elements may differ from one another rather in form than in substance, or even that the whole seventy are only modifications of a prime element; but chemical analogies seem wanting. The closest analogy would be if we could prepare two allotropic conditions of some body, such as phosphorus or cyanogen, which should carry their allotropism into all their respective compounds, no compound of the one form being capable of change into a compound of the other. Our present knowledge of allotropism, and of variations in atomicity, affords little if any, promise of this.

The remarkable relations between the atomic weights of the elements, and many peculiarities of their grouping, force upon us the conviction that they are not separate bodies created without reference to one another, but that they have been fashioned or built up from one another, according to some general plan. This plan we may hope gradually to understand better; but if we are ever to transform one of these supposed elements into another, or to split up one of them into two or three dissimilar forms of matter, it will probably be by the application of some method of analysis hitherto unknown.

Nothing can be of greater promise than the discovery of new methods of research; hence I need make no apology to others who have lately done excellent work in chemistry if I single out the Bakerian Lecture of this year, by Mr. Crookes, on "Radiant Matter Spectroscopy." It relates to the prismatic analysis, not of the light transmitted or absorbed in the ordinary way by a solid or liquid, nor of that given out by incandescent gas, but the analysis of the fluorescence that manifests itself in certain bodies when they are exposed to an electric discharge in a highly exhausted vacuum. He describes, in an interesting and even amusing manner, his three years' quest after the origin of a certain citron band, which he observed in the spectrum of the fluorescence of many substances, till he was led into that wonderful labyrinth of uncertain elements which are found together in samarskite, and eventually he proved the appearance to be due to yttrium. As the test is an extremely delicate one, he has obtained evidence of the very general dissemination of that element, in very minute quantities—and not always very minute, for the polypes that built up a certain pink coral were evidently able to separate the earth from the sea water, as their calcareous secretion contained about $\frac{1}{2}$ per cent. of yttrium. We have reason to hope that this is only the first instalment of discoveries to be made by this new method of research.

I cannot conclude without a reference to the brightening prospects of technical chemistry in this country. I do not allude to the progress of any particular industry, but to the increased facilities for the education of those engaged in the chemical manufactures. First as to the workpeople. Hitherto the young artizan has had little opportunity of learning at school what would be of the greatest service to him in his after career. The traditions of the Middle Ages were all in favour of literary culture for the upper classes, and the education suited for these has been retained in our schools for the sons of the

* This exception includes not merely such changes as that from a ferrous to a ferric salt, but the different ways in which the carbon is combined in such bodies as ethene, benzene, and pyrene.

people. It is true that some knowledge of common things has been given in the best schools, and the Education Department has lately encouraged the teaching of certain sciences in the upper standards. In the Mundella Code, however, which came into operation last year, "elementary science" may receive a grant in all the classes of a boys' or girls' school, and in the suggested scheme there is mentioned simple lessons on "the chemical and physical principles involved in one of the chief industries of England, among which Agriculture may be reckoned," while "Chemistry" is inserted among "the specific subjects of instruction" that may be given to the older children. It is impossible, as yet, to form an estimate of the extent to which managers and teachers have availed themselves of this permission, for the examinations of her Majesty's inspectors under the new code have only just commenced; but one of the best of the Board schools in London has just passed satisfactorily in chemistry both with boys and girls. I trust that in those parts of the country where chemical industries prevail chemistry may be largely taken up in our elementary schools.

The great deficiency in our present educational arrangements is the want of the means of teaching a lad who has just left the common school the principles of that industry by which he is to earn his livelihood. The more purely scientific chemistry, however, may be learnt by him now in these evening classes which may be formed under the Education Department, as well as in those that have long been established under the Science and Art Department. The large amount of attention that is now being given to the subject of technical education is creating in our manufacturing centres many technical classes and colleges for students of older growth.

As to inventors and the owners of our chemical factories, in addition to the Chemical Society and the Chemical Institute, there has recently been founded the Society of Chemical Industry. It came into existence with much promise of success; at the close of its second year it numbered fourteen hundred members; it has now powerful sections in London, Manchester, Liverpool, Newcastle, and Birmingham; and it diffuses information on technical subjects in a well-conducted monthly journal.

May the abstract science and its useful applications ever prove helpful to one another, and become more and more one chemistry for the benefit of mankind.

Parliamentary and Law Proceedings.

Prosecution under the Patent Medicines Act.

At the Leeds Police Court, on December 14, before Mr. Bruce, James Barrett and William Lynch, shopkeepers, both of Meanwood, were charged with exposing for sale certain patent medicines without having obtained a licence, thereby rendering themselves liable to a penalty of £20. The defendants' shops had been visited, and it was found they were vending Keating's teething powders. The defendants pleaded ignorance of the requisitions of the law. They were each fined 10*s*. and costs.

Fatal Explosion of a Mixture.

At the Manchester City Coroner's Court, on Friday, December 21, before Mr. Sydney Smelt, City Deputy-Coroner, an inquest was held relative to the death of Wm. Turley, a shingler, late of 49, Gladstone Street, Warrington, aged 51 years, who died the previous day at the Royal Eye Institution, John Street, in that city. The circumstances were somewhat singular; and the inquiry occupied the court several hours. It appeared that on Wednesday week deceased went to the shop of Mr. J. H. Woods, a pharmaceutical chemist, carrying on business at 18, Butter Market Street, Warrington, for three pennyworth of quicksilver and three pennyworth of aquafortis. He had been in the habit of purchasing similar quantities of aquafortis and quicksilver in order to mix them into a kind of ointment which was applied in some way to his master's family. Deceased had a son employed by Mr. Woods as his errand boy, and the lad was present when his father came in to make the purchase. The boy says that the chemist served his father with both articles, and that they were placed in the same bottle, and that his father said to the chemist "Will it be all right?" to which Mr. Woods replied, "It's all safe." Deceased then placed the bottle in his breast pocket and left the shop, but shortly afterwards the stuff exploded and the contents of the bottle burnt the face and eyes of the poor fellow so seriously that he died, as stated, at the Manchester Eye Hospital, having been removed there from the Warrington Infirmary. In his voluntary statement Mr. Woods said that he had never known the mixture to explode before, though he had always served deceased with the articles separately, generally placing the quicksilver in a pill box. He should not have mixed the two, but deceased, after being served with the quicksilver, pushed the bottle towards him, and said "Give me three pennyworth of aquafortis." The cork did not fit tightly.

Mr. A. Hill Griffith, house surgeon at the Eye Hospital, said deceased was admitted suffering from severe burns over the face and eyes. Death resulted from collapse and shock. If aquafortis and quicksilver were put in the same bottle a strong gas would be given off, resulting most likely in the bursting of the bottle, or the sending out of the cork, the catastrophe being hastened by the heat from the body.

Mr. George Massy, chemist, Deansgate, gave similar evidence as to the formation of volatile gas from such a combination. He had often sold the two things together in one bottle, but always without a cork.

The Jury, in reply to the Deputy-Coroner, said they were unanimously in favour of a verdict that would be favourable to Mr. Woods, the death of the deceased being due partly to his own negligence and partly to the negligence of Mr. Woods.

The Deputy-Coroner said such a verdict would be equivalent to a verdict of manslaughter against Woods. Under the circumstances the inquest was adjourned until Wednesday next for the production of further evidence. —*Manchester Courier*.

Sale of Strychnine without Registration.

At the Worcester Borough Police Court, on Dec. 21, Mr. E. J. Kitson, chemist and druggist, Broad Street, attended in answer to a summons for a breach of the Pharmacy Act, 1868, by having sold to William Underwood strychnine, without, before delivery of the same, making or causing to be made an entry in a book which is kept for that purpose, stating the date of sale, name and address of purchaser, name and quantity of the article sold, the purpose for which it was stated by the purchaser to be required, and neglecting to obtain the signature of the purchaser.

William Underwood, son of Detective Underwood, proved the purchase of the poison, which was contained in a packet of "Kitson's Worcestershire Rat Killer," for which he paid 3*d*.

In defence, Mr. Kitson said his assistant had strict orders to carry out the provisions of the Act. This offence was committed without his knowledge, as he was away at the time.

A fine of £1 11*s*. 6*d*., including costs, was inflicted.

E. J. Clark.—Thanks for your communication.

Pharmacist.—It would be illegal for an unqualified person to carry on business, even with the aid of a qualified manager. For the grounds upon which the House of Lords held that certain bodies are exempt from this prohibition see the judgment (*Pharm. Journ*., [3], xi., 104).

Communications, Letters, etc., have been received from Messrs. Abraham, B. Redwood, G. Brown, Wrighton, Inquirer, A. P. S., M. M.

The Pharmaceutical Journal.

SATURDAY, JANUARY 5, 1884.

Communications for the Editorial department of the Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary,* 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

1883.

IF ever another section should be added to the 'History of Pharmacy,' the year that has just closed will have to be described as politically one of expectation and preparation rather than of achievement. It is true hopes were raised more than once during the twelve months that it would be possible to make a mark favourable to pharmacy upon the statute book; but they were frustrated by causes that hindered much other projected legislation. Nevertheless, the preparatory work was not altogether without result, for it was the occasion of the manifestation of a considerable amount of unanimity amongst the chemists and druggists of the country, which in one instance resolved itself into a hint of considerable significance. If, however, all was not accomplished that had been intended, the year was by no means uneventful in its pharmaceutical aspects, as will appear from the following paragraphs.

Assuming, as is reasonable, that the Council of the Pharmaceutical Society is essentially the executive for all the registered chemists and druggists in the country, we take up first the record of its doings. The Council has undergone no change in its constitution during the year. The fourteen members who retired in May according to the bye-laws were all of them re-elected, and at the meeting of the Council in June, Mr. M. CARTEIGHE was requested to continue in office as President, Mr. ATKINS as Vice-President, and Mr. ROBBINS as Treasurer. At its earliest meeting in the year the Council devoted several hours to the discussion of a draft of a Pharmacy Act Amendment Bill that had been prepared by the Law and Parliamentary Committee. The details were not then, however, published, as it was thought desirable that the Committee should first confer with the officials of the Privy Council on the subject. At the meeting in February the subject again came up for discussion, on the report of the Committee recommending the adoption of the draft Bill, which it was then decided should be printed. When the Bill came to be published it was found that in the preamble greater emphasis was laid upon the expediency for the safety of the public that *sales* of poisons and dispensing of prescriptions should be regulated than in the Pharmacy Acts of 1852 and 1868, where the regulation for the qualification of *sellers* of certain poisons had been most prominent. Perhaps the least expected feature in the Bill was a provision in this spirit to regulate the sale of certain articles which can be sold under present circumstances by unregistered as well as registered persons. It was proposed to effect this by instituting a new class of scheduled articles, to be termed "poisonous," and making their sale subject to certain restrictions as to labelling. This step had been taken after long consideration and in consequence of urgent representations from a body representing a class of persons who considered they were exposed to danger and injury by the unrestricted sale of the articles referred to. As a first instalment it was proposed that this "poisonous" schedule should include sulphuric, hydrochloric and nitric acids, butter of antimony and carbolic acid, all articles which may be sold without any restriction as to vendor or label. It is important to remember that these substances had been all included in a list of articles which the Council of the Pharmaceutical Society, acting under its statutory powers, had in 1882 resolved it was desirable to add to the second part of the poison schedule, though the Privy Council had declined to approve the resolution. Another provision in the draft Bill had for its object the preservation during at least twelve months of a record of the details of all sales of poisons contained in the first part of the schedule. Another regulation extended to patent medicines and would have made it illegal to sell by wholesale or retail any such articles containing a poison within the meaning of the Pharmacy Act, 1868, unless the box, bottle, package or vessel in which the same was contained, the wrapper if there were only one, or the outermost wrapper if there were more than one, were labelled with the name and address of the first seller of the same, the name of the patent medicine and the word "poison." In the case of a "duly qualified keeper of an open shop for the sale of poisons" becoming subject to a penalty for breach of this provision in respect of a patent medicine not prepared by himself he was to have a right of indemnity against the person who supplied him with it, this right passing to all intermediate dealers until the real offender was reached. The unqualified keeper of an open shop had no such remedy and under another clause of the Bill he would be breaking the law in selling by retail a patent medicine containing a "poison." With respect to persons carrying on business, perhaps the most important provision was one to extend the scope of the present law and make it illegal for any person "to sell by retail, or to keep open shop for "retailing, dispensing or compounding medical pre-"scriptions or (whether as patent medicines or "otherwise) poisons" within the meaning of the Pharmacy Act, unless he were qualified by registration or came under the exemption as a trustee or administrator of the estate of a deceased pharmacist. In order to make the law more effective it was provided that in every case the seller upon whose behalf the sale was made should be deemed to be the person to whom the regulations as to the sale of poisons applied, whilst any assistant, apprentice or other servant was to be deemed to be simply the agent of the seller on whose behalf the sale was made. It was also provided that words importing the singular number only should include the plural, and in order to meet any case where doubts might exist as to the real owner or owners of a shop, it was proposed to give the Registrar power to serve an application for such information, requiring its delivery within seven days under a penalty. The Bill also proposed to make it unlawful for any qualified keeper of an open shop for retailing, dispensing or compounding medical prescriptions or poisons to keep open shop in more places than one without placing a qualified person *bonâ fide* in charge of each branch shop. Other clauses had for their object the conferring upon the Council the power to make, alter and amend by bye-laws the regulations as to examinations, and also to make it illegal for a chemist and druggist to take as an apprentice a person who was not registered as having passed the Preliminary examination. The promoters of the Bill, in addition, contemplated making an important alteration in the constitution of the Pharmaceutical Society, in that it was provided that every person who after December 31, 1886, might pass the qualifying examination under the Pharmacy Act, 1868, should be entitled to be registered as a "pharmaceutical chemist" and be eligible as a "member" of the Pharmaceutical Society; whilst any person who before that time might have been registered as a "chemist and druggist" in virtue of having obtained a certificate of qualification from the Board of Examiners would be eligible as a "member" of the Society, but not entitled to registration as a "pharmaceutical chemist."

The foregoing sketch will sufficiently reveal the nature of the draft Bill in the form in which it was adopte[d b]y the Council, and it includes all the points that subs[e]quently became the subjects of adverse criticism. Within a short time of its publication meetings of chemists and druggists were held at nearly all the principal provincial centres, at which, as a rule, the provisions of the Bill were considered *seriatim*, the result being a more or less emphatic expression of approval of the Bill as a whole in every case. We think this is quite a sufficient refutation of an *ex cathedrâ* dictum put forth a short time since by a person who is a member of the executive of the Trade Association, though not a registered chemist and druggist, to the effect that the Bill had not been framed by the true representatives of the chemists and druggists of Great Britain. Indeed it would appear probable that the speaker himself had forgotten for the time that at the annual meeting of the Trade Association the members had formally resolved that it was "most suitable that chemists and druggists generally, should be united in support of the Pharmacy Bill." The points which gave rise to the greatest amount of objection were those relating to the institution of a schedule of "poisonous" articles, the provisions as to the labelling of patent medicines containing scheduled poisons, the requirement of qualified managers for branch shops, and the proposition which would result eventually in only one grade of legal qualification and one kind of membership of the Society. The objections to the "poisonous" schedule proceeded from a somewhat unexpected quarter, and were not based upon the assumption of any possible restriction of trade by the regulations applying to the articles in that schedule, this point indeed having been satisfactorily disposed of by the majority of replies to the inquiry previously made by the Council throughout the country through the medium of the local secretaries. The objectors, who had Mr. G. F. Schacht for a leading spokesman, saw in the imposition of regulations applying to unregistered persons who sold such substances as it was proposed to class as "poisonous," a departure from the broad principle hitherto advocated by the Society that in the interest of the public only qualified persons should be allowed to deal in any such dangerous substances. In fact they preferred that the practice should remain as it is rather than the Society should recognize in any way the traffic in poisonous substances by unqualified persons. When the Bill was under the consideration of the executive of the Trade Association, this view was endorsed by a majority of 7 to 5, and a resolution was passed that among the amendments to the Bill to be suggested should be one to the effect that the whole of the clause dealing with the subject should be erased and the articles in the special schedule added to the second part of the poison schedule. This suggestion, with others, was in due time transmitted to Bloomsbury Square, but unfortunately without any mention of the manner in which it was contemplated that the latter part of the proposed amendment was to be carried into effect in the face of the opposition of the Privy Council. On the other hand, it was known that the Government had announced its intention of promoting legislation further to regulate the supply of poisons, and an indication had been given of its views upon the subject in the refusal of the Privy Council to approve the resolution of the Council of the Pharmaceutical Society that the articles specified ought to be included in the existing schedule. Moreover, it appeared to many that the restriction as to labelling would exercise an influence in the direction desired. It was, therefore, thought wiser by the majority of the Council and, we believe, of the trade, to recognize the situation and by responding to the good will of the Government, manifested in the request for advice, to bring a legitimate influence to bear in the interest both of the public and the trade. The criticisms of the provisions as to patent medicines were of a two-fold character. One took the form of an objection to the retail vendor being made primarily responsible for insufficient labelling, with a right of indemnity, instead of limiting the responsibility to the maker. The subject was discussed at the Annual Meeting of the Society, on a motion made by Mr. G. W. SANDFORD to the effect that the clauses should be altered, which, notwithstanding the suggestion that the incoming Council should be invited to reconsider the clauses, was carried by a small majority. The other criticism was that the word "and" should be inserted so as to ensure that the outer wrapper, as well as the containing vessel, should be always labelled "poison," and it was also suggested to require the name of the poison to be mentioned. The objections made as to the clause necessitating the passing of the Preliminary examination before apprenticeship have not been very numerous, whilst those directed against the requirement of qualified managers for branch shops, though in some instances originating in a dislike to the giving of any sanction to one person being proprietor of more than one business, have, as a rule, been somewhat sentimental and mainly based upon considerations of hardship in particular cases, although the provisions would affect none disadvantageously but those who have chosen to ignore the legislation of 1868. Lastly, although there have been some remonstrances against what has been termed the abandonment of the Major qualification, which phrase, however, does not describe what is intended quite correctly, the proposition has on the whole been received in the most liberal spirit by those who have acquired the title of "pharmaceutical chemist" by undergoing voluntarily an extra examination. As previously remarked, no very obvious result has attended all this preparatory work. The draft Bill was communicated to the Government and in March Mr. MUNDELLA announced that it was intended to introduce a Bill into the House of Lords, though little was revealed as to its nature beyond the statement that it would deal with patent medicines containing poisons. But the Government intentions in this direction, as well as in others, were frustrated and the session slipped away before anything further was done. The subject came up at the meeting of the Council last month, on the reading of a stimulant communication from the Lincolnshire Association for the Prevention of the Administration of Poisonous Drugs to Horses. The President then stated that he had reason to believe the subject was still under the consideration of the Government; but Mr. BOTTLE and Mr. HAMPSON appeared to be of opinion that if the Government does not soon move in the matter the Council should take steps to introduce a Bill independently.

In March a Bill for the Consolidation and Amendment of the Law relating to Medical Practitioners was introduced by Lord CARLINGFORD into the House of Lords. It proved to be essentially a Bill for reducing to order the incongruities at present affecting the system of medical examination and for the protection of medical titles; but it was free from the class of provisions in regard to "counter practice" that have made several previous medical bills obnoxious to chemists and druggists. The Bill dealt, however, with one subject in which pharmacists are closely interested, the preparation of new editions of the national Pharmacopœia, in regard to which it provided for a continuance of the existing arrangements, ignoring the opinion formally recorded by the Council of the Pharmaceutical Society that practical pharmacists should be associated with any future Pharmacopœia Committee. At the April meeting of the Council, therefore, Mr. HAMPSON moved that, as the Bill contained no provision by which pharmacists would be empowered, conjointly with members of the Medical Council, to revise and prepare future editions of the British Pharmacopœia, a Committee should be authorized to take steps to remedy the omission. The motion was carried unanimously and, as a consequence, it was reported at the next meeting that the President of the Society had had an interview with the Lord President of the Council, and had ascertained from him that the Government was not disposed to agree to the principle of the desired alteration in the Bill. Meanwhile it had become known, by the publication of an official report, that the Medical Council had long before made arrangements for the preparation of a new edition of the Pharmacopœia and that several months previously Professors REDWOOD, BENTLEY and ATTFIELD had been engaged to carry out the work under the direction of the Pharmacopœia Committee. The subject was broached at the May meeting of the Council by Mr. GREENISH, who expressed his disapproval of the course that had been taken by the Professors, a sentiment that was endorsed by several other members. Subsequently a copy of a printed memorandum, similar to others sent to many individuals resident in different parts of the country, was addressed to the President and Council of the Pharmaceutical Society, stating that the Pharmacopœia Committee would be happy to receive suggestions and to give them their most attentive consideration. It was unanimously agreed that this was not the form or degree of representation on the Pharmacopœia Committee to which pharmacists should be entitled, and it was resolved, if necessary, to oppose the Bill in Parliament, authority being given for the drawing up and sealing of a petition for presentation to Parliament if necessary. A similar view of the general subject was taken by the Council of the Pharmaceutical Society of Ireland, which found expression in a memorial presented to Lord CARLINGFORD and a petition to Parliament that was confided to the President of the British Society for presentation at an opportune moment. A few days afterwards a memorial was drawn up for presentation to the Privy Council, in which the case of the pharmacists was briefly stated and the insertion of a new clause in the Bill was suggested to the effect that a Pharmacopœia Committee should be established consisting of six medical practitioners, to be nominated by the Medical Council, and five Pharmaceutical chemists, four to be nominated by the Pharmaceutical Society of Great Britain (one to be resident in Scotland), and one by the Pharmaceutical Society of Ireland. Notwithstanding every effort, however, the Bill went down to the House of Commons without alteration in the direction desired. It was, therefore, felt that the time had come to prepare for making the influence of the trade felt in a constitutional manner. A form of petition, based upon the memorial was drawn up, copies of which were supplied to Local Secretaries of the Society in the provinces and to leading pharmacists in London, and through the praiseworthy efforts of those gentlemen, upwards of two hundred well-signed petitions were soon ready for presentation through the local members of Parliament upon reception of a notice from the Committee. The Bill, however, made little progress, having been "blocked" in the interests of some of the medical corporations affected by it, and the petitions were not presented until August, a few days before the Bill, notwithstanding much pertinacity on the part of the Premier, received its quietus by withdrawal before it had been read a second time. There is reason to believe, however, that the authorities have now become more appreciative of the views of pharmacists upon this subject, and it is hoped that this will become apparent in any future Medical Bill.

Another parliamentary Bill that occupied the attention of the Council was the Patents Bill, which, as originally introduced, contained a provision relating to the use of the royal arms, which might have become a source of great vexation to pharmacists, as well as to tradesmen generally. Attention having been called to the clause by Dr. SYMES, it was decided that an attempt should be made to effect its modification. After some correspondence, the Board of Trade drew up an amended form of the clause and suggested that if satisfactory the Council might arrange for this to be moved on the report of the Bill; the amendment was accepted as satisfactory, and was eventually adopted in Parliament. The Explosives Bill was passed in such haste that no time was given for its consideration; but immediately after it had passed attention was called in these columns to its possible aspect towards chemists and druggists carrying on a certain class of trade, and this view was confirmed subsequently by a communication from the Home Secretary. In order, therefore, to prevent as far as possible annoyance as the result of ignorance, our readers were supplied with a *résumé* of the Orders in Council applying to the sale and keeping of explosives. Bills for the amendment of the law of partnership and the registration of firms, both of which would have to some extent affected the working of the Pharmacy Act, were introduced into Parliament, but failed to pass, and the same fate befell a Petroleum Bill.

Education and examination are subjects that every year occupy a large portion of the time of the Council. In March a Committee appointed to consider the best method of giving effect to the resolution passed by the Council in the previous year in respect to the establishment of a curriculum presented a report. The Committee made sundry recommendations which it was suggested should, with those previously adopted, be incorporated into the bye-laws, and come into force after the end of 1887. The chief feature in the Report was a recommendation as to the division of the qualifying examination into two parts, one of them to be a written examination on prescriptions, pharmacy and theoretical chemistry, to be conducted in London and Edinburgh and certain local centres; the other to be *vivâ voce*, dealing with practical dispensing, botany, materia medica and chemistry, and confined to London and Edinburgh. This recommendation was practically identical with one that had been rejected in the previous year, the only difference being that the proposed interval between the two parts of the examination had been extended from six months to one year. The proposition was strongly opposed by Messrs. HAMPSON and WILLIAMS, who looked upon it as *ultra vires*, and by Mr. GREENISH, who objected to a written examination upon prescriptions and pharmacy. On a division, however, the report was adopted by a large majority. The subject then lapsed until August, when Mr. SCHACHT urged that steps should be taken to carry out the resolution of the Council, and in October a Committee was appointed to frame, with the assistance of the Solicitor, the necessary modifications in the bye-laws. In May the sanction of the Council was given to the new regulations for conducting the Preliminary examination which will come into force for the first time at the examination to be held next week. These regulations are altogether favourable to the candidates, since they secure a longer and definite time for each subject, and in the Latin a choice of one of two authors is given.

Whatever may be the amount of deterrent influence exercised by inroads of unqualified competitors or the stringency of the examinations, these causes combined are insufficient to prevent an increase in the number of aspirants to enter the business of a chemist and druggist. The gross number of persons who came up for examination last year reached 2426, being an increase, as compared with the previous year, of 396, in which all the examinations shared. For the Preliminary examination there were 1539 applicants, against 1260 in 1882, of whom 770 passed, or just 50 per cent., showing again a slight improvement. There were also 93 certificates received in lieu of examination, making no less than 863 persons who thus crossed the threshold of pharmacy. The legal qualifying, or Minor, examination, which had in respect of the number of candidates remained stationary at about 650 for three previous years, rose last year to 766; but the failures were very numerous, only 294 or 38·4 per cent. having passed, so that notwithstanding the largely increased number of candidates only six more persons became entitled to registration than in 1882. The statistics as to the Major examination are relatively satisfactory; for there were 111 candidates, of whom 55, or 50 per cent. passed, against 103 candidates in the previous year, with 60 per cent. of failures. In view of the large proportion of failures in the Minor examination, which might suggest the idea that it is made unduly stringent, it is important to note that Dr. Greenhow, the Government visitor at the examinations held in London, in his last report says that whilst it may possibly happen that a rather weak candidate occasionally passes, he believes that no competent candidate is ever rejected. Dr. Maclagan, too, the Government visitor at the examinations held in Edinburgh, in his report says that he "cannot attribute the large "proportion of failures to any other cause than the "want of preparedness, and the ignorance of what "constitutes preparedness, on the part of the candi- "dates." Indeed, he expresses an opinion that if the project of the Council be carried out with respect to the unification of the examinations an effort should be made to "raise the standard of the pass examination at least up to the level of the present Major." Whilst referring to these reports it may be mentioned that with respect to the proposed division of the examination, and the conducting of one portion in writing at local centres, Dr. Greenhow holds views resembling those of Mr. Greenish, and he also looks with disfavour upon the proposal to make a curriculum compulsory.

The Benevolent Fund has, as always, been the object of much solicitude on the part of the Council; nor is there any reason to be dissatisfied with the result. The yearly income to this noble fund is now a large one, and it is dispensed in the most catholic manner. There is still reason to regret that so small an interest is taken in it by the greater number of chemists and druggists who are not members of the Pharmaceutical Society, and in February last, the Council tried to cope with some of this indifference by sending a copy of this Journal, containing a list of the subscribers and a statement of the manner in which assistance is given, to every chemist and druggist on the register. The income during the year, independent of the interest upon invested capital, amounted to £1922 2*s.*, consisting of £1535 17*s.* in subscriptions, and £386 5*s.* in donations. On the other hand the expenditure has amounted to £1964 5*s.*, the sum of £1283 15*s.* having been spent in annuities, and £680 10*s.* in casual relief. During the year the list of annuitants has been decreased by seven, through death; but it has also been augmented by the election last month of six new annuitants, making the number now forty-one, of whom thirty-one are in receipt of £35 a year, they being over sixty-five years of age. For these annuities the annual responsibility amounts to £1385, and assuming that the casual relief granted in the coming year will reach the sum given in the past, it will be seen that upwards of £2000 will be required to meet the probable expenditure in 1884.

Among other subjects that have occupied the attention of the Council has been that of the investment of the capital of the Society, which previously had been made exclusively in Government funds. At the meeting in March the Finance Committee in its report recommended that a portion, not exceeding three-fourths of the invested capital, should be reinvested as occasion might offer in freehold ground rents or freehold ground. An amendment was moved by Mr. Williams, but the recommendation was adopted. The reference to the subject in the Report of the Council provoked some criticism from Messrs. Sandford and Stacey at the Annual Meeting, but no adverse motion was made and the resolution has since been acted upon to some extent. Another transaction was in respect to a desire that had been expressed that in addition to the class of Honorary Members of the Pharmaceutical Society at present in existence there should be a class of Corresponding Members, to be elected annually under similar conditions and to consist of persons who have distinguished themselves in connection with pharmacy or the allied sciences. In January the subject was, on the proposition of the President, referred to a Committee, which in March reported in favour of the suggestion, and recommended that a bye-law for the institution of such a class should be drafted ready to be brought forward at a convenient opportunity. In March, too, the Committee to which the subject of the importation and sale of spurious and worthless drugs had been referred reported that the practice was not on the increase and did not need further legislation to control it, but recommended the appointment of a permanent Committee to receive information, collect specimens and have them examined, and publish occasional reports. A committee was, therefore, appointed in accordance with the recommendation.

In the course of the year about one hundred and twenty reports of alleged infringement of the Pharmacy Act, in the selling of scheduled poisons by unregistered persons, were received by the Registrar. In the majority of cases any illegal practice that was being carried on was discontinued upon the receipt by the offender of an official letter of warning. In some cases, however, where the offence was persisted in, the authority of the Council to institute legal proceedings was given, and in certain instances it became necessary to recover penalties. There have also been about a dozen cases of prosecution under the 17th section of the Pharmacy Act reported, some of which have been instituted by the executive of the Trade Association and others by the police. There have been a few prosecutions of chemists and druggists under the Sale of Food and Drugs Act, one conviction being obtained for the substitution in dispensing a prescription of cinchonidine sulphate for quinine sulphate, and another for the substitution of sodium salicylate for methyl salicylate. Another batch of cases with respect to the alleged sale of defective spirit of nitrous ether and tincture of quinine were of a very trivial nature and were most of them dismissed. There have also been three convictions under the Patent Medicine Act, apparently due to forgetfulness of the fact that the recommendation of any preparation for internal use as a medicine necessitates the use of a stamp. One curious action brought against a chemist for damages resulting from the loss of a dog, which had helped itself to poisoned food during its perambulations on the wrong side of the counter, was very properly dismissed; but in another action, where loss of life resulted through substitution of a preparation of aconite for one of actæa, damages were awarded, which, it is understood, were paid by the wholesale firm in whose establishment the mistake originated. About an average number of cases of accidental poisoning have been reported, amongst which the particular poisons that the Council of the Pharmaceutical Society has attempted to bring under restriction figure prominently. One of the most noticeable, a glaring case of poisoning by a so-called patent medicine, will be found on another page of the present number.

With the month of May came the Annual Meeting of the Pharmaceutical Society, which was numerously attended. The Report of the Council and the verbal commentary upon it which constituted the President's address were well received, and although the curriculum scheme was the subject of some criticism and an amendment it was warmly defended and the Report was eventually adopted *nem. con.* Mr. Sandford then brought forward a motion for the alteration of the clauses in the draft Bill relating to the responsibility for imperfect labelling of patent medicines containing poison, which, as already stated, was carried. On the evening preceding the meeting the members of the Society and their friends dined together as usual, being favoured with the company of the Lord Mayor and Sheriffs, and a number of distinguished medical and other scientific men. On the evening of the meeting the usual Conversazione was held at South Kensington, which was also largely attended.

The Inaugural Meeting of the Session held in October, was rendered notable by two events. After the usual reports of the Professors, which it is hardly necessary to say were commendatory of the past students, and the distribution of the prizes, an admirable address was delivered by Professor Michael Foster, F.R.S., upon the subject of examinations. This was followed by the presentation of the Hanbury Medal to Mr. John Eliot Howard, F.R.S., to whom it had been awarded by the Committee constituted in accordance with the trust-deed. The occasion was one of deep interest and no one present could have anticipated that the eminent quinologist, who seemed to bear his years so well, would pass away within a few weeks from the time of receiving the honour. One drawback to the evening's proceedings was the announcement that the examiners were again, as two years previously, unable to award the Pereira Medal. With respect to the ordinary Evening Meetings it may be stated that the supply of papers has been moderately well sustained, the number read during the past year having been fifteen as compared with ten in the previous year. It may fairly be said also that most of them were of considerable interest, as will be seen from the following list:—"A Research on the Alkaloid Gelsemine and Some of its Crystalline Salts," by Mr. A. W. Gerrard; "Uranium Oleate," by Mr. W. Gibbons; "Liquid Extract of Cinchona," by Dr. B. H. Paul; "The Bitter Principle of Hymenodictyon Excelsum," by Mr. W. A. H. Naylor; "Remarks on Some Medicinal Plants of Ceylon," by Dr. W. C. Ondaatje; "Note on Essence from Green Ginger," by Dr. C. Symes; "A Note on Sap," by Professor Attfield; "The Classification and Properties of Red Resin known under the Name of Dragon's Blood," by Messrs. Dobbie and Henderson; "The Preparation of Lard for Use in Pharmacy," by Professor Redwood; "Notes and Suggestions upon Tincture of Nux-Vomica," and "On Extract of Nux-Vomica," by Messrs. Dunstan and Short; "Tincture of Cinchona," by Mr. E. G. Hogg; "The Alkaloidal Strength of Tinctura Cinchonæ Flavæ," by Mr. J. O. Braithwaite: "The Purgative Principle of Croton Oil," and "The Vesicating Principle of Croton Oil," by Mr. H. Senier. It it much to be regretted, however, that the Evening Meetings of the Society are not used by a larger number as a means of bringing forward the results of observations in practical pharmacy, which must often involve points that could be more profitably and conveniently discussed on such occasions than in any other way.

Among the educational appliances of the Society the Library and Museum hold a conspicuous place. It is satisfactory to be able to report that there has again been a marked increase in the attendance, the numbers having been 6011 in the daytime and 1764 in the evening, against 4260 and 1513 in 1882. The books taken out from the Library have been 3238, or within a dozen of the number of the previous year. During the same time about three hundred books and pamphlets have been received. An extensive manuscript 'Bibliography of Pharmacy' has also been acquired, and is now available for reference. In the Museum considerable alterations have been made. With the view of rendering its resources more available for purposes of study the crowded specimens in the Materia Medica Museum have been thinned out and those only left in it which it is desirable that students should become acquainted with; specimens which are chiefly used for purposes of comparison or reference, or which have only an historical interest, as well as the collections illustrative of the Indian and United States Pharmacopœias, have been removed into a new handsome series of cases around the walls of the examination room. Additional tables have also been placed in the Materia Medica Museum to permit of a larger number of students using the specimens at the same time. Another feature, which it may be hoped will prove useful to visitors, is the addition of a case for the exhibition of recent donations to the Museum or of new remedies, so that drugs or chemicals of recent introduction may be easily seen. This case will probably be open to inspection early in 1884. The Museum has been enriched during the past year by the addition of a valuable series of cinchona barks from the Government plantations and gardens in Madras, Darjeeling, Ceylon and Jamaica, their value being still further enhanced by a collection of herbarium specimens obtained from the identical trees from which the bark was gathered, and the fact that in many cases the bark is accompanied by the report of an analysis of it made by Dr. PAUL. Among the more noteworthy of the additions to the collection of foreign drugs may be mentioned a series of Japanese drugs, presented by the Director of Kew Gardens; a number of Brazilian drugs, presented by Messrs. T. CHRISTY and Co. and Messrs. SYMES and HALLAWELL; some interesting specimens of native Natal drugs, from the Curator of the Botanical Gardens, Mr. J. M. WOOD; some Cinghalese remedies, from Dr. ONDAATJE; a very interesting collection of specimens from Mr. R. JAMIE, of Singapore, including a section of the stem and foliage of the Siam benzoin tree, which has been hitherto unknown, as well as a very complete and valuable series of the different varieties of the famous ginseng root of China; and a series of drugs used by the Cree Indians of Hudson's Bay Territory, from Mr. W. HAYDON. The attendance in the Museum during the year amounted to 6268, being 5064 in the morning and 1204 in the evening. Some of the donations to the Museum are, we believe, in sufficient quantity to permit of chemical examination, and the Curator will no doubt be pleased to hand such to any competent gentlemen who are willing to investigate them.

The North British Branch of the Pharmaceutical Society would appear to have had a fairly prosperous year. The Library and Museum continue to be well appreciated, and our pages bear evidence that the Evening Meetings have been marked by the reading of some extremely valuable papers. At the Annual Meeting in April a favourable Report was presented, and Mr. ALEXANDER NAPIER having retired from the presidential chair, Mr. JOHN NESBIT, who had in the previous year been Vice-President, was chosen to fill the office of President, whilst Mr. HENRY BELLYSE BAILDON succeeded him as Vice-President.

In the sister island the course of events has transferred the Pharmaceutical Society of Ireland from a temporary shelter in the King's and Queen's College of Physicians to a home of its own in Harcourt Street, Dublin. The Annual Meeting was held in October, and it is much to be regretted that the address of Professor TICHBORNE revealed the fact that the characteristic negligent indifference of pharmacists is even more marked in that country than in this; for although more than two hundred licentiates had been enrolled in the thirteen years the Irish Pharmacy Act had been in operation, only between sixty and seventy were then members of the Society. Considerable activity has been manifested by the Council in enforcing the law, though legal proceedings will probably prove too expensive a luxury to be long indulged in unless the income of the Society is increased by the adherence of a larger proportion of those interested in keeping trespassers off the domain of pharmacy. Early in the year a request was received from the Government for information as to the working of the Sale of Poisons Act, Ireland. In reply, it was stated that by duly qualified pharmaceutical chemists and apothecaries the provisions as to labelling, etc., were carried out, but that they were ignored by the large class of general tradesmen, who under the Act are in Ireland allowed to deal in poisons; and it was recommended that in order to exercise some control the registration of all sellers of poison should be made compulsory. The Council has also had under its consideration the amendment of the Pharmacy Act, Ireland, and, as already mentioned, it joined with the British Council in endeavouring to secure the proper representation of pharmacists upon future pharmacopœia committees. A resolution having been adopted, at the suggestion of Professor TICHBORNE, limiting the term during which the office of President might be held continuously by one person, that gentleman, who had ably presided over the Society since he succeeded Sir DOMINIC CORRIGAN in 1878, vacated the Chair, and Mr. J. E. BRUNKER was elected the new President, Mr. DRAPER being chosen as Vice-President and Mr. HODGSON as Treasurer.

The Trade Association of Great Britain held its Annual Meeting in London in May. The Report presented cannot be described otherwise than as a gloomy one, since it showed a decrease in the income associated with a diminished balance, and in the words of the Vice-President there appeared to be a threatening of a financial collapse. An energetic attempt was to be made to place affairs on a better footing, which we heartily hope may succeed; for the past history of the Trade Association shows that within its proper sphere such a body is capable of rendering great service in respect to the trade interests of chemists and druggists. No doubt the falling off is partly due to the prevalence of more peaceful conditions in the trade; but the very fact that such an organization is known to be in existence, and can be appealed to, is an influence for good, and to neglect to support it except under the temporary excitement of harassing prosecutions may prove to be the source of regret when too late. Mr. HAMPSON having declined to serve another year as President, Mr. HARRISON, of Sunderland, was elected to succeed him in the office.

The annual gathering of the British Pharmaceutical Conference was held in Southport, in September, and was well attended. It was marked by the delivery of an extremely vigorous address by the President, Professor ATTFIELD, which had more of a political character than is usual in communications to the Conference. Assuming that it was the intention of the Legislature in passing the Pharmacy Act, in 1868, to give to persons who qualify under its provisions a practical monopoly in the supply of medicine to the public, it was not very difficult to prove that no such result had ensued, and a rather gloomy future for British pharmacists was suggested as probable if the Legislature did not interfere to ensure that its original intention should be carried out. The address was extremely well received, and was the topic of an unusual amount of editorial comment in the daily papers, much of which purported to be in favour of some legislation, though somewhat incoherently and with much difference of opinion as to its extent and nature. The scientific and practical papers read at the meeting were quite up to the average in quantity and quality, and most of them will be noticed elsewhere. The British Association also met in Southport, immediately after the close of the Conference, under the presidency of Professor CAYLEY. The American Pharmaceutical Association met in the same month at Washington, and the German Association in Wiesbaden, and both of the meetings appear to have been successful. In Vienna the first International Pharmaceutical Exhibition was held under the auspices of one of the Austrian Imperial Princes, and both in respect to the exhibits and the number of visitors it proved a very satisfactory experiment. Another meeting presenting points of interest to pharmacists was that of the Social Science Association at Huddersfield, in October, when papers were read on the amendment of the law relating to poisons by Professor TIDY and Mr. G. L. BROWNE. The former gentleman advocated the abolition of an authoritative schedule of poisons, arguing that the onus should be thrown upon the seller of deciding what articles he would treat as poisons, and he also maintained that in not issuing compulsory regulations as to the storage of poisons the Pharmaceutical Society had neglected a duty imposed upon it by law. The opportune presence of the President of the Society at the meeting, however, allowed of some light being thrown upon the question from another point of view. Amongst other societies that deserve special mention may be instanced some consisting mainly of junior pharmacists, such as the School of Pharmacy Students' Association, members of which have contributed valuable papers to the meetings of the Pharmaceutical Society and of the Conference, the Chemists' Assistants' Association in London, and a similar association in Edinburgh. At Hawick a new association has been started that promises to do well, and still more recently a students' association has been commenced at Hanley.

It cannot be said that the past year has yielded any very important contribution to the vegetable materia medica, such new remedies as have been recommended—and these have been not a few—consisting principally either of contributions from the chemical laboratory or new applications of old medicines. Neither has the year been so fruitful as some of its predecessors in the elucidation of obscure points as to botanical origin, some little advance made towards the identification of the tree yielding Siam benzoin and the contribution made by Drs. DOBBIE and HENDERSON to the history of the resins passing under the name of "dragon's blood" being almost the only noticeable incidents. The article which has probably occupied the pen most has once more been cinchona bark, one fact becoming more and more apparent that although cinchona cultivation is still increasing in different parts of the world, especially in Ceylon and Jamaica, considerable uncertainty exists as to the exact species that are being grown. It is evident that until this confusion is cleared up the commercial cultivation of the plants can only be carried on by rule of thumb, and the assistance the chemist would be capable of rendering to the cultivator will be minimized through the shortcomings of the botanist. Nevertheless some interesting facts have been placed on record, and one or two of these point to the probability that when the botanist has done his work, he will only have made it still more evident that the cultivator must always look to the chemist to help him to decide under what conditions of growth any species or variety of *Cinchona* may be made to produce the most favourable yield of alkaloid. In the first place Dr. TRIMEN has reported some experience with what were believed to be succirubra plants all raised from one kind of seed, which seems to show that elevation has a great influence on the development of alkaloids, nearly twice as much alkaloid being found in the bark grown at a height of 5500 feet as in the bark grown at 1500 feet, whilst the alkaloid in the former case was mainly lævorotatory (quinine and cinchonidine) and in the latter case principally dextrorotatory (cinchonine and quinidine). Analyses made by the late Mr. J. E. Howard of barks from different elevations in Jamaica and in Ceylon appeared to confirm this inference, and it is worth mentioning that in all the cases the bark grown at the lower elevation, though considered to have the best appearance, was poorest in alkaloid. Mr. D. Howard has recorded the observation that whilst in renewed bark produced on trees after stripping according to Mr. McIvor's plan, in which alternate strips are removed down to the cambium, the proportion of quinine is higher than in the original bark, the reverse is the case in renewed bark produced after the "shaving" process, in which the bark is usually removed uniformly and superficially, the tendency being then to develop cinchonidine at the expense of quinine. He also states, as evidence of the field there is for skill in the selection of cinchonas for cultivation, that he has met with original "red bark" yielding 4 or 5 per cent. of quinine, whilst calisaya bark from individual trees, grown in Ceylon under apparently similar conditions, varied from 3 to 9 per cent. in their yield of quinine. Such a result is perplexing; nevertheless, the general results seem to show that, other things being equal, the plants yielding the most valuable barks grow in the richest soil, which is quite in accord with what might be expected and also with the experience of Mr. Broughton, published a dozen years ago. A similar lesson as to the relative effect of the depth to which the bark is removed appears to be taught by some analyses, made by Mr. J. Hodgkin, of different pieces of Ceylon succirubra quill bark taken from the same consignment, some being natural, some renewed, and some partially natural and partially renewed on the same piece. In the renewed portion of the natural-renewed quill, where the shaving removed would necessarily be decreasingly thin, the quantity of quinine was less than in the entirely natural quills, while the cinchonidine was more than double. The entirely renewed bark showed an increase of quinine equal to 75 per cent., which more than outstripped the increase in cinchonidine. The cinchonine did not show much variation, but there appeared a considerable diminution of alkaloid in the natural bark in juxtaposition to the renewed bark. Similar results have been obtained before, though Mr. Hodgkin has been the first to make them known. Of course the value of any inferences drawn from these results would be dependent upon the extent to which the different pieces analysed were comparable one with another. Dr. Hesse has added two more to the already long list of cinchona alkaloids,—concusconine and concusconidine,—and he has endorsed the claim of the substance isolated from cuprea bark almost simultaneously by three sets of observers to be considered a new alkaloid. He, as well as others, has failed to obtain the crystalline compound of quinine and quinidine which was rather too hastily assumed to have been mistaken for a new alkaloid, but Messrs. Wood and Barrett have now published definite instructions for the preparation of this compound, as well as compounds of quinine and quinidine and quinine and cinchonidine with benzene, the difference in form of crystallization of which they state may be used as a delicate test for an admixture of cinchonidine with quinine sulphate.

Whilst on the subject of cinchona bark, it may be mentioned that Dr. Paul, having been struck by the fact that a sample of professedly B.P. liquid extract of cinchona contained only a very small amount of quinine, was induced to examine several other samples collected from different sources and found that they all agreed in containing but a very small proportion of quinine, varying from mere traces up to 2 grains per fluid ounce. As the liquid extract, if it fully represented the alkaloidal contents of an official bark, would contain about 35 grains to the fluid ounce, Dr. Paul made further experiments to ascertain whether an explanation was to be found in the official process being insufficient for the complete exhaustion, in which he used a sample of ordinary "flat calisaya," as now met with, and a sample of Indian bark, both of known composition. Upon analysing the liquid extracts made according to the B.P. process and the residual marcs, it was found that only about one-seventh part of the alkaloids in the original barks had passed into the preparations. These results were communicated to the Pharmaceutical Society at an Evening Meeting and gave rise to an animated discussion, Professor Redwood maintaining that the official conditions as to the choice of a bark had not been complied with, and that, therefore, the experiments could not be used as criteria in estimating the value of the official process. A remark made by Dr. Paul to the effect that he could not confirm a statement by Mr. Ekin as to the tincture being a good preparation led that gentleman to request Messrs. Hogg and Braithwaite to make some independent experiments, the results of which went to demonstrate the correctness of Dr. Paul's statement, that after the preparation of a tincture of cinchona by the official process as much alkaloid remains in the bark as the spirit has taken out. Connected with this discussion a bye-controversy was started in respect to the well-known preparation of the late Mr. Battley, which, however, revealed little beyond the fact that that gentleman knew better how to keep a secret than was commonly supposed.

Considerable progress was made during the year in working out the chemical and pharmaceutical history of nux-vomica and its preparations, in a series of investigations conducted by Messrs. Dunstan and Short. The first step was to contrive a process for the analysis of the drug, which consisted in exhausting the powdered seeds in an ingeniously contrived apparatus with a mixture of chloroform and alcohol, removing the alkaloids from this mixture as acid sulphates by shaking with dilute sulphuric acid, and then after decomposing with ammonia taking up the liberated alkaloids again with chloroform. When this process was applied to specimens of seeds authenticated as from Bombay, Cochin and Madras, it was found that their richness in alkaloid corresponded with the order in which they are named, ranging in one series from 3·46 per cent. in Bombay to 2·74 in Madras seeds. This variation, which had previously been suspected, having been established, it followed naturally as a corollary that it should be reproduced in the preparations, as indeed appeared in a paper sent by the same authors to the Conference meeting, giving the results of analyses of a dozen commercial specimens of tincture of nux-vomica. In this paper, the authors, availing themselves of the insolubility of strychnine ferrocyanide in dilute sulphuric acid as a means of separating that alkaloid from brucine, were able to show that not only did the proportion of total alkaloid vary, but that there was also a variability in the relative proportions of the strychnine and brucine present. In the results obtained, however, there were signs of another cause of variability in tinctures of nux-vomica, besides the quality of the seeds, which induced the authors to experiment as to the effect of using alcohol of different strengths, and they came to the conclusion, laid before an Evening Meeting last month, that the best results were obtainable in using a mixture of 100 volumes of rectified spirit with 25 of water as a menstruum. Practically the same results were arrived at by Mr. Conroy, who having called attention to the probability after the reading of the first paper, had been working independently on the subject. The use of sodium chloride to assist in the preparation of tincture of nux-vomica seeds had been recommended by Mr. Rother on chemical grounds; but Messrs. Dunstan and Short came to the conclusion that though the exhaustion of the seeds is facilitated by it, which they attribute to a physical and solvent action, the ultimate practical gain is doubtful. In a report upon twelve specimens of extract of nux-vomica the same authors showed that, as was to be expected, the range of variability in total alkaloid and in the relative proportion of strychnine and brucine was quite as great in that preparation, a fact that effectually disposes of the suggestion that the extract might be used as a basis for preparing a uniform tincture.

The bark of *Hymenodictyon excelsum*, which is used in India as a tonic bitter, has been investigated by Mr. Naylor, with the result of disproving the presence of æsculin, which had been alleged, and the isolation of an alkaloid free from oxygen, to which the bitterness appears to be mainly due, which he has represented by the formula $C_{24}H_{40}N_3$ and named "hymenodictyonine," and a peculiar neutral principle. Cusparia bark has yielded to Messrs. Körner and Böhringer three hitherto unknown alkaloids, two of which they have named "cusparine" and "galcipine." Mr. Gerrard has succeeded in obtaining "gelsemine," the characteristic alkaloid of the root of *Gelsemium sempervirens*, in a crystalline form, and as the result of analysis has attributed to it the formula $C_{12}H_{14}NO_2$. Dr. Hay has reported the isolation from *Cannabis indica* of a new alkaloid, which from its physiological properties he has called "tetanocannabin." Theobromine has been found to accompany caffeine in the kola nut by M. Schlagdenhauffen, the compliment being returned, according to Herr Schmidt, by caffeine accompanying theobromine in the cacao nib, where, Dr. Galippe says, it always has copper for a neighbour. Among other contributions to the history of the vegetable bases made during the year may be mentioned the reported isolation of "nigelline" and "connigelline" from the seeds of *Nigella sativa*; of "abrotine," from the common southernwood; of "doundakine," from a West Indian febrifuge bark known as "doundaké," and of "buxinidine," from *Buxus sempervirens*, as well as the formation of an "apo" derivative from colchicine. From oleander leaves Dr. Schmiedeberg has separated one glucoside which he has named "neriin," but which may prove to be identical with digitalein, and another less active that he has called oleandrin, and Mr. H. G. Greenish has given some further information respecting the bitter principles found by him in the allied *Nerium odorum*. Dr. Schmiedeberg has also obtained "apocynin" and "apocynein" from the root of *Apocynum cannabin*, and has pointed out that these, with the oleander glucosides and some other substances, form a group of active principles resembling digitalin in their physiological action, and some of them capable of replacing it with advantage in the treatment of certain forms of heart affection. Neutral principles have also been reported as having been isolated from "manaca" (*Franciscea uniflora*) and "Jamaica dogwood" (*Piscidia erythrina*); and also a camphor from *Lippia mexicana*.

At the February Evening Meeting Messrs. Dunstan and Ransom communicated two interesting papers, which threw light on the action of chlorine upon sodium carbonate in solution, as well as on the constitution of the official liquor sodæ chloratæ, which is generally stated to contain sodium hypochlorite, chloride and bicarbonate. Availing themselves of the observation that hypochlorous acid is soluble in ether, whilst the sodium salt is not, the authors were able to satisfy themselves that during the passage of chlorine gas into a solution of sodium carbonate under the B.P. conditions the sodium hypochlorite at first formed is all decomposed by more chlorine and the final product is a liquid containing free hypochlorous acid, sodium chloride and sodium bicarbonate. If, however, the passage of chlorine be continued beyond this point, the whole of the sodium bicarbonate is decomposed, hypochlorous acid and sodium chloride being formed. In view of this conclusion it was significant that no commercial specimen of liquor sodæ chloratæ examined yielded free hypochlorous acid to ether, but they all gave abundant evidence of the presence of sodium hypochlorite, and the authors therefore concluded that they had been obtained by the decomposition of a solution of bleaching powder with sodium carbonate. Another investigation, reported by Mr. Dunstan, had a bearing upon the chemistry of glycerinum and mel boracis, and was a continuation of previous experiments of the author as to the action of some polyhydric alcohols on borax. His observations went to show that when anhydrous glycerol acts upon anhydrous borax, it combines with half the boric anhydride contained in the salt to form an ethereal salt which he terms "glycerol borin," sodium metaborate remaining. This glycerol borin is decomposed by water, with the formation of boric acid, a reaction that explains the acidity of aqueous solutions of borax and glycerine. In the case of mel boracis there appears to be a liberation of boric acid by the action of the dextrose and levulose contained in the honey upon the borax in presence of water, sodium metaborate being also formed in this case.

A most interesting paper on acetic ether was in March read before the North British Branch by Dr. W. I. Clark; it contained the results of a large amount of experimental work upon the composition, specific gravity and solubility of that compound, so that its value was scarcely diminished by the fact that it was originally undertaken under a misconception as to the Pharmacopœia formula. Once more phosphoric acid has been the subject of a fresh suggestion for its preparation. In a paper read before the Pharmaceutical Association, Professor Wenzell described a process which consisted simply in the oxidation of stick-phosphorus by atmospheric air in the presence of moisture. By far the principal product under these conditions is phosphoric acid; some phosphorous acid, together with ozone, hydrogen peroxide and ammonium nitrate being also formed. Professor Runyon has since reported that he has used this process on the manufacturing scale with favourable results. The introduction into the German Pharmacopœia of a test for benzoic acid, which in order to secure a product sublimed from the resin was based apparently upon the presence of an accompanying impurity, has given rise to a vast amount of discussion. It was evident that the reduction of potassium permanganate, in which the test consisted, could be effected by other compounds than the one in question, and some interesting experiments made by Mr. Dymond, a student in the School of Pharmacy, appear to show that the condition is complied with even by a solution of impure urine benzoic acid. A still more interesting observation made by Mr Dymond is that when benzoic acid prepared from hippuric acid is submitted to sublimation it can be obtained in a form in which in odour, colour and behaviour towards the official tests it exactly resembles benzoic acid extracted by lime from Palembang benzoin. It may be mentioned here that although it has been asserted that the medicinal activity of sublimed benzoic acid depends upon a small quantity of an essential oil volatilized with it, some experiments made with a quantity of this oil by Messrs. Gehe appeared to show that it is practically inert. The nature of the deposits sometimes formed in liquid pharmaceutical preparations has been frequently the subject of speculation, but Mr. Cripps has made a praiseworthy attempt to determine their relative importance. The deposits from a number of different tinctures, collected from various sources, were examined, and as a general result it may be stated they were found to consist principally of starch, colouring matter, and other inert substances. Following up the subject of the solubility of calcic hydrate in water at different temperatures, started by Mr. A. C. Abraham, Mr. Maben has placed on record the results of a number of experiments from which he infers that the temperature of a shop rarely rises above the point at which water will hold in solution the quantity of lime required in the official liquor calcis, and that the explanation of the cases of defective lime water which have been the subject of prosecution is not to be found in that direction. He thinks it more likely to lie in the conditions under which lime intended for the preparation of lime water is kept in stock, since these often favour the production of carbonate. Nevertheless, even with equal parts of hydrate and carbonate Mr. Maben obtained a lime water containing equal to 0·5 gram of calcic oxide per fluid ounce. A singular error which had crept into the United States Pharmacopœia process for the estimation of hydrocyanic acid, has been pointed out by Mr. Cripps, and Mr. Siebold has given reasons for occasionally supplementing the B.P. test by the American one.

In a valuable paper on aromatic spirit of ammonia, read at the Evening Meeting in February, Dr. Thresh described a process which he said yielded a more uniform preparation than the official one. It consisted in distilling the essential oils with the spirit, dissolving the ammonium carbonate and solution of ammonia in the last portion of the distillate with the aid of a moderate heat, and after filtration mixing the two solutions. It was suggested during the discussion that it would be preferable to avoid even this amount of distillation and simply dissolve the essential oils in the spirit. Sweet spirit of nitre was the subject of still another paper, read before the Conference by Mr. A. C. Abraham, in which he suggested a process based on the intervention of calcium nitrate, provided for by the introduction of calcium carbonate instead of copper, as in the official process, which he sai gave a cheap and satisfactory product. Some examinations, made by Mr. W. H. Symons, of commercial samples of spirit of nitrous ether, have revealed considerable deviations from the official requirement and suggests that as long as these commercial preparations find favour amongst chemists and druggists, public analysts will not be at loss for a field in which occasionally to display their official activity. The examination of a sample of iodine liniment which emitted a pungent and irritating vapour led Mr. MacEwan to the conclusion that in its preparation methylated spirit had been used. This opinion received confirmation from other sources and the unpleasant result is considered to be probably due to the formation of iodo-allyl compounds from allyl alcohol present as an impurity in the wood spirit used. Preparations of ferrous iodide have yielded the usual crop of suggestions for their preservation, the principal ones being the addition of a few drops of alcohol immediately after the completion of the combination of the iodide with the iron in the preparation of the solution, the covering of the syrup with a layer of oil, the incorporation of a certain proportion of glucose with the cane sugar in the syrup, and the use of a mixture of glycerine and glucose syrup, which Mr. Percy Wells believes is destined one day to supersede cane sugar syrup in pharmacy.

A considerable amount of attention was devoted during the year to preparations having a basis of fat or a mixture of the paraffin hydrocarbons. The subject was treated in a very comprehensive fashion at the Conference Meeting by Mr. Willmott, who gave the results of a large number of experiments, extending over several years, and made with lard, oil and wax and mineral hydrocarbons. He expressed an opinion that the washing of lard, as ordered in the Pharmacopœia, is without advantage if not detrimental, an opinion which was subsequently confirmed in a paper read by Professor Redwood. In mixtures of oil and wax he found that substances met with under the name of "white wax" formed an unstable element, yellow unbleached wax yielding much more permanent preparations. He also noticed that some of the mineral hydrocarbons develop a disagreeable odour under certain conditions. At the same meeting the possibility of using sesame oil as a substitute for olive or almond oil was reported upon independently by Messrs. Conroy and Maben, the general impression conveyed by the papers being that its use in pharmacy will be limited. Mr. Maben also contributed earlier in the year a valuable paper upon the preparation and composition of nitrate of mercury ointment, in which he pointed out that the omission from the official formula of a statement of the temperature at which the ointment is to be prepared allows of a great variation in the product, which may either be an ointment of elaidate of mercury or an ointment of nitrate of mercury. The disputed question as to the amount of iodine present in cod liver oil has been taken up by Mr. Stanford, than whom no person could be more competent. Taking the average of six specimens from different sources, he found the mean percentage to be 0·000322, a quantity far below what has been asserted in text books. In fact, Mr. Stanford said if these statements had been true, cod liver oil would have been one of the richest sources of iodine known. Iodine, however, appears to be present in minute quantities in many other fish besides cod; indeed the herring contains about four times as much. Incidentally, Mr. Stanford described a very delicate test for iodine in oil. The general subject of the analysis of oils has been dealt with in an able paper by Mr. A. H. Allen, and a similar service for turpentine oil has been rendered by Dr. Armstrong. A further examination of croton oil has been made by Mr. H. Senier, who finds that whilst the portion not soluble in absolute alcohol constitutes the purgative principle, the portion that is soluble in it represents the vesicant property. A suggestion for using this portion of the oil in the preparation of blistering plasters has already been made. With respect to essential oils M. Naudin has pointed out that when they are distilled without the application of heat by means of methyl chloride they are extremely delicate in odour and very stable. Mr. Wells also has made the practical suggestion that the odour and quality of essential oils and distilled waters may be improved and the decomposition of the latter prevented by the addition of a little potassium permanganate to the water before distillation.

From the foregoing it will appear that the past twelve months were very fruitful in respect to the chemical aspects of pharmacy. But a number of other subjects are worthy of mention, being of considerable practical importance, such as the suggestion of Dr. Symes to use "green" ginger in the preparation of an essence of ginger; the preparation of pomegranate bark described by Mr. Siebold; suggestions for the dispensing of potassium permanganate in pills; the use of gelatine, collodion, and solution of gutta percha in the preparation of external dressings, and of wood wool and sphagnium moss for a similar purpose, as well as Dr. Symes's upward filter and Mr. Maben's drying closet. Dr. Quinlan's suggestion of ensilage as a method of preserving medicinal herbs is worthy of further investigation; but judging from the changes known to take place in hay and other fodder whilst in the silo, it cannot be expected that the product would represent exactly the fresh plant. The recommendation of new remedies has also brought some fresh substances under the manipulation of the pharmacist, amongst which may be mentioned paraldehyd, bismuth salicylate, sodium hippurate, the goose-grass and the mullein with its "spike of gold."

Every year brings fresh evidence as to the importance of the *rôle* played by organisms belonging to what are usually esteemed to be the lowest forms of life, and it cannot be ignored that not only such industries as brewing, vinegar making, wine fermenting and bread making, but also the practice of medicine, and, consequently, that of pharmacy, have been profoundly affected by the discoveries made in this direction. During the past year it has become more and more probable that such apparently widely separated diseases as cholera, leprosy, phthisis, whooping cough, gonorrhœa and yellow fever are all attributable to the disturbing influence of specific organisms. Consequently, the search for antiseptics continues, and among those brought forward more or less prominently have been mercuric chloride, trichlorphenol, naphthol, salicyl-resorcin-ketone, various antiseptic tows and carbonic anhydride. The interesting observation has been made that the peculiar action of an infusion of jequerity seeds in setting up factitious ophthalmia is also due to the presence of a bacillus, which is capable indeed of producing much more serious results. Further, the demonstration of the existence of organisms in the soil capable of such widely differing operations as the production of various alcoholic fermentations, the formation of nitrates and their decomposition, and the reduction of sulphur compounds, has afforded a glimpse at a subterranean laboratory of which the existence was, until recently, little suspected.

The book market has been as prolific as ever, and many valuable works more or less closely connected with subjects within the scope of pharmacy have been published. In botany, the *magnum opus* has been the 'Genera Plantarum' of BENTHAM and HOOKER, which has been brought to a close after years of persevering work by the authors. Of a more humble sort, but very valuable in its way, is a 'Student's Guide to Structural, Morphological and Physiological Botany,' which Professor BENTLEY has sent out. Messrs. VAN GORKOM and MOENS, two well-known authorities upon cinchona cultivation, have both published manuals upon the subject. Professor FLÜCKIGER has completed a second edition of his 'Pharmacognosie,' and a want in English literature had been supplied by Mr. H. G. GREENISH's able translation of the 'Plant Analysis' of Professor DRAGENDORFF. 'Fownes's Chemistry' has undergone further necessary modification at the hands of its editor, Mr. WATTS, whose name it now bears. Mr. BLYTH has given us a new work on 'Poisons' and a fresh edition of his 'Analysis of Food.' An entire army of books has resulted from the publication of the new Pharmacopœias for Germany and the United States, including a fresh edition of the celebrated 'Dispensatory.' Even while we write the new 'Year-Book' has come to hand; whilst, least in size, but one of the most welcome to the practical pharmacist, the 'Extra-Official Pharmacopœia' has made its way through a first and well into a second edition during the last half of the year.

The history of no considerable section of the community for a year can be written without having to chronicle the death of good men and true. Among the friends that pharmacy lost during the past year, may be mentioned Mr. WILLIAM SQUIRE; Mr. JOHN ELIOT HOWARD, who only a few weeks previously to his death had received the Hanbury Medal; Mr. JOHN HENRY ATHERTON, a former member of the Council of the Pharmaceutical Society; Mr. BENJAMIN HUMPAGE, a former Auditor and an ever-welcome attendant at the annual meetings; as well as Messrs. HOLLWAY, of Cardiff, Mr. HATRICK, of Paisley, Mr. RALPH DAVISON, of York, and Mr. DUNCANSON, of Stirling, all of whom had served the Society in the office of Local Secretary. Several of the "Founders" of the Society have also passed away, and a connecting link with its early history has been removed in the widow of Dr. JONATHAN PEREIRA.

We have thus once more endeavoured to weave into a coherent whole the story of the scattered incidents of another year. In doing so we have endeavoured to keep strictly within the limits of pharmaceutical subjects; but much more might have been written without going further afield than the changes which are revolutionizing the alkali industry, the progress of research in pure chemistry and physics, and the application of scientific principles to technical industries. We suspect, however, that the patience of some of our readers has already been sufficiently tried, and we lay down the pen with the wish that the year which is opening may be remarkable for the advancement of the true interests of pharmacy and the prosperity and happiness of all who follow it as a calling.

On Monday evening next, the London Section of the Society of Chemistry will hold a Conference in the rooms of the Chemical Society, Burlington House, to consider and discuss the subjects of the "Desirability of Uniform Methods and Bases of Analysis" and the "Practicability of Establishing an International Agreement concerning them." Representatives from the Chemical Societies, the Pharmaceutical Society, the Society of Public Analysts and other associations have been invited to attend.

*   *   *

Within the last few days the authorities at the Patent Office have issued, in a pamphlet form, the new rules for the registration of trade marks, with the classification of goods and a table of fees, which will apply under the Patent Act that came into operation on Tuesday last. We propose to supply a *résumé* of the rules in next week's Journal.

*   *   *

The *soirée* of the Associated Scientific Societies of Liverpool, which has now become an annual event, was held at St. George's Hall, on the 19th ult. It passed off with great *éclat*, more than three thousand ladies and gentlemen having been present.

*   *   *

A meeting of the School of Pharmacy Students' Association will be held on Thursday next, January 10, at 8 p.m., when a paper on "Hydroxylamine" will be read by Mr. W. H. Ince, and a Report upon Inorganic Chemistry will be made by Mr. Lowe.

Provincial Transactions.

EDINBURGH CHEMISTS' ASSISTANTS AND APPRENTICES' ASSOCIATION.

The fifth meeting of the sixth session was held in the Pharmaceutical Society's rooms, 119A, George Street, Edinburgh, on December 26, at 9.15 p.m. Mr. Claude F. Henry, President, in the chair.

The minutes of the previous meeting having been read and confirmed, the President called upon Mr. George Coull to read a paper on some of the "Pharmacopœial Gum-Resins."

Selecting scammony and myrrh as being the most important gum-resins, the essayist gave a very interesting historical account of these drugs. Referring to the collection of scammony, he showed how want of care on the part of peasant collectors tends to lower the value of the product, and that low quality is not only due to carelessness but to intentional adulteration and sophistication. The various adulterants were then mentioned and means for their detection given. After briefly referring to the chemistry of the drug, he proceeded to speak of myrrh on the same lines; a most interesting part of this portion of the paper being that in which he treated of the botanical origin of the varieties of this gum-resin. The paper was well illustrated by diagrams and a full series of specimens.

The President, in moving a vote of thanks to Mr. Coull, said that the paper which had been read was a proof of the good influence of the Association, the writer having been a member for two or three years and one of the Association's prizemen. The paper reflected great credit on Mr. Coull, and was particularly commendable from the fact that he was still an apprentice.

Mr. Joseph Low seconded the motion, which was heartily accorded.

A discussion then took place, in which Messrs. Crowden, Hill, MacEwan and Thomas Stephenson took part.

Several queries were then submitted, and replied to by Messrs. Coull, Hill, Low, Robertson, Thomas Stephenson, Turnbull and others.

The President having intimated that the next meeting would be held early in January, when papers will be read by Messrs. Robbie and Stephenson, apprentice members of the Association, the meeting adjourned.

LIVERPOOL CHEMISTS' ASSOCIATION.

Soap Manufacture and the Soap of Commerce.*

BY ALFRED SMETHAM, F.C.S.

The manufacture of soap, although known in early times, has during the present century reached wider proportions than at any previous period, and has been the study of scientists who, without altering the fundmental principles of the manufacture, have made many improvements in the details. Formerly the term soap was applied to a variety of substances of an oleaginous nature, but it has now become narrowed to those substances used for domestic and industrial purposes for the removal of grease and dirt.

The soaps thus used are classed under two heads—soft and hard. The former is a compound of potash or potash and soda in combination with the fat of a drying oil: but it is simply with the hard soaps that I wish to deal this evening.

Until comparatively recent years the whole of the soaps manufactured were obtained by the action of a solution of soda upon an oil or tallow, sometimes with the addition of rosin; but with increased knowledge and greater competition, various additions have been made which, if not improving the quality, have certainly had the effect of cheapening the production.

* Read at a meeting of the Association, November 8, 1883.

But whether a pure soap or a mixed one be desired, the first proces is the same, viz., the saponification of a fat or as it is technically called the production of curd. To effect this, the fat to be operated upon is placed in large boilers or pans, around which are coiled pipes to conduct steam. The lye, which is solution of caustic soda, is then run in until the whole of the fat is saponified or decomposed. This, then, is the principal operation of soap making and it will be well to consider in what this consists.

Most of the oils and fats used by the manufacturers are complicated organic substances known as glycerides of the fatty acids. This may be more clearly stated, perhaps, by saying that they are a combination of fatty acids with glycerine. In the saponification of a fat the glycerine is displaced by the soda used, and a neutral soda salt formed in its place.

Thus if the fat operated upon were pure stearine we should have the following reaction:—

$$\underset{\text{Stearine.}}{\left.\begin{matrix}(C_{18}H_{35}O)_3\\ C_3H_5\end{matrix}\right\}O_3} + 3\,NaHO = \left.\begin{matrix}C_3H_5\\ H_3\end{matrix}\right\}O_3 + \left.\begin{matrix}(C_{18}H_{35}O)_3\\ Na_3\end{matrix}\right\}O_3$$

The fats, however, are more complicated, and generally cousist of a mixture of fatty acids such as stearic, oleic and palmatic in combination with glyceryl.

In England the chief ingredient of pure soaps is tallow. This is the fat obtained from sheep and oxen, the quality varying somewhat according to the source. As found in the market it is generally white or of a very light brown colour, contains only traces of moisture, and is practically free from mineral salts. Sometimes, however, the colour is dark and the percentage of water is found to be considerable. Unless it has suffered decomposition it is found to be a mixture of neutral fats, consisting chiefly of stearine and olein.

The fat next in importance to tallow is palm oil. This, as it arrives in this country, is a moderately soft fat, of a bright yellow or orange colour, and generally contaminated with variable proportions of water and dirt. It is, therefore, customary to sell it upon a fixed basis as shown by chemical analysis. Owing to the crude methods of production by the natives a portion of the neutral fats have become decomposed, and fatty acids in appreciable quantities are sometimes met with.

The yellow colour of the oil renders it unfit for use without previous bleaching. This is commonly performed by what is known as the bichromate method—a process which is equally applicable to dark-coloured samples of tallow.

The oil is first melted in a caldron and the dirt allowed to subside. The purified oil is then run off into a second vessel and treated with an aqueous solution of bichromate of potash and an excess of sulphuric and hydrochloric acids or hydrochloric acid alone.

The acid first decomposes the bichromate thus:—

$$K_2Cr_2O_7 + 2\,HCl = 2\,KCl + H_2O + 2\,CrO_3.$$

The chromic acid thus set free is again decomposed by the excess of acid with the formation of chromic chloride and nascent oxygen, the latter of which by oxidation destroys the colouring matter of the oil. The second reaction is principally as follows:—

$$2\,CrO_3 + 6\,HCl = Cr_2Cl_6 + 3\,H_2O + O_3.$$

Although I have expressed the reaction which takes place by two equations so as to render the changes more intelligible, the two decompositions really proceed simultaneously and in one operation. The resulting sesquichloride of chromium and the chloride of potassium are found in the water below, and the bleached oil floats on the surface and can be readily removed.

From the above equations it will be seen that the theoretical proportions are as nearly as possible equal quantities of bichromate and hydrochloric acid; but in practice it is necessary to use a large excess of acid in order to ensure the complete reaction, and acid from two to three times the weight of the bichromate employed is generally used. The acid in these quantities has no detrimental effect upon the oil and the exact proportion is, therefore, of no moment.

Besides the two fats already specified a large number of oils are extensively used. Olive oil is commonly employed upon the Continent, but is rarely used in this country. At home cotton seed oil, palm nut oil (a white solid fat, differing widely from palm oil) and cocoa nut oil are most frequently used. When the price is sufficiently low, castor oil and lard, and occasionally other oils, are used in the manufacture.

All these oils are essentially of the constitution before mentioned. The liquid oils are usually rich in olein, whereas palm nut oil and cocoa nut oil are rich in palmitin. On saponification they all yield about one-tenth of their weight of glycerine, which has to be removed by a process to be presently mentioned. This glycerine is now, I believe, being successfully recovered from the spent lyes, and should, at the present prices, leave a wide margin for profits.

Besides the fatty matters, rosin or colophony is employed in the manufacture of yellow soaps. This differs essentially from the fats, and is really a mixture of organic acids known as pinic, sylvic and colophonic acids. These are capable of combining directly with an alkali and forming compounds analogous to those derived from fats, but in the combination no glycerine is formed, and the use of rosin, therefore, reduces the percentage of glycerine in the spent lyes.

The alkali invariably used in the production of hard soap, is, as I have said, soda. In order to decompose the fats it is necessary for it to be in an uncombined or caustic condition, and the presence of even carbonic acid prevents saponification from taking place. The soda used in this country is obtained from common salt by decomposition with sulphuric acid. The sulphate so formed is again treated with coke and chalk and submitted to a high temperature. By this means carbonate of soda is produced which, purified by lixiviation and subsequent evaporation and heating, forms the soda ash of commerce. This it was which until the last few years was sold to the soapmaker, who, after dissolving it, causticized it by the addition of lime. The process was wasteful and required considerable room, which considerations have led to the manufacture of caustic soda by the alkali maker, and the use of soda-ash by soap boilers is now a thing of the past. Some of the largest manufacturers of soap make their own alkali, and thus not only save the profit on the alkali, but also the cost of concentrating the caustic solution, a point of no small consideration when the output is large.

Having now briefly described the raw materials at the disposal of the soap maker, we are in a position to understand the processes which are adopted for their conversion into soap. The boiler first supplies himself with a weak solution of caustic and then melts in a pan a quantity of the fat to be operated upon. The sp. gr. of the lye—as the solution of alkali is called—should not in the first instance exceed 1·050–1·060. The heat is maintained by means of steam, the direct use of a fire being now practically obsolete. The first action of the caustic is to produce an emulsion, and when this is properly formed more alkali is added, the strength of the lye being gradually increased. The reason why a weak lye must be used in the first instance is that soap is insoluble in a strong solution of caustic and the particles of fat would by the use of a strong lye become incased in an insoluble layer of soap which would prevent further action from taking place. The lye is added in until an excess of caustic is found in the pan. More oil or fat, or where required, rosin is then added, and the fat or rosin saturated by subsequent additions of lye. When the operator by examining the texture of the soap considers the reaction complete, the watery solution of soap and glycerine is decomposed by the addition of salt, in a solution of which soap is insoluble. The soap then rises to the surface in a finely divided state, and after complete separation the spent lye is removed. After the removal of the lye the soap is again heated, and if necessary, some weak lye added, so that the soap may assume a "close" texture, as it is called. When this is complete the soap is removed, usually by pumping, to another vessel where it is "crutched." This consists essentially in stirring the mass by rotating arms moved by machinery by which means the soap is brought into condition, and if of too great consistency more water is added. It is now ready for the frames, composed of slabs of wood or iron placed together in a rectangular form, and made in such a manner that when the soap has solidified the sides may be removed. The soap is left in the frames until it is completely set. When this has occurred, the block is taken out and cut into slabs by means of a wire pulled through it in a horizontal direction. The slabs thus formed are placed upon a table with a movable arm across which wires are stretched and the slabs are by this means again divided into bars. It is then, if it be a pure soap, ready for packing. Sometimes, however, it is desired to make up the soap in tablets of given weight. It is then cut up into pieces of the requisite weight and stamped in a press with dyes, the presses usually being worked by hand.

This, then, is a brief outline of the manufacture of a genuine soap; but the exigencies of the case render it necessary to produce a variety of soaps, at cheap prices. This has been brought about by competition and the inability of the public to discriminate between a well-made and a common soap, and consequently it is impossible for any firm manufacturing only pure soaps of high quality to hold its place in the struggle for existence. The cheaper soaps being more readily soluble in water produce a lather more quickly than a pure soap, and as the public does not as a rule make comparative trials as to the lasting powers, and is almost invariably led away by a cheap article, the sale of the best soaps has of late fallen off considerably, and the cheaper kinds have taken their place.

Although I have used the term pure soap to represent a soap manufactured from fat and alkali alone it would be unfair to designate the common soaps adulterated, as we shall see on considering their nature.

A pure tallow soap will only take a certain proportion of water and it becomes necessary to mix other substances with it if the percentage of water is increased. A substance which is useful in this respect, and which at the same time has detergent properties, is silicate of soda. This is the substance known as soluble glass, but it is usually sold to the soap boiler in solution. It is composed of silicic acid and soda in various proportions, and is formed of two kinds, the neutral and the caustic. The neutral has a sp. gr. of about 1·370 and contains about 65 per cent. of water. The proportion of silicic acid is about 26 per cent. and the remainder is soda and impurities. The caustic silicate is a much heavier solution and has a specific gravity of about 1·700. It contains about 43 per cent. of water, 33 per cent. of silicic acid and the remainder alkali and impurities.

These solutions are either used alone, or in combination, and are added to the soap before finishing. It is necessary to "crutch" well to ensure the complete mixing, and the crutching should be continued until the soap is about to set. The silicated soaps generally contain a larger proportion of water than pure soaps, besides the actual weight of silicate, and they can, therefore, be produced at lower prices. The detergent power of these soaps is greater than would be indicated by the pure soap contained in them, and in many districts this variety finds a market more readily than the better qualities. I should here point out that the value of a soap is not altogether determined by the composition. A pure soap may be produced from a discoloured tallow or oil, which as a rule injures the appearance and causes it to command a less value in the market.

A form of silicated soap which obtains a large sale is the mottled. This differs essentially from the mottled soap manufactured a few years back, which was pure, and necessarily of a high standard. It is usually manufactured from bleached palm oil, or from palm nut oil or cocoa nut oil as the chief ingredient. It is usually run with silicate to a considerable extent and contains a variable amount of fatty acids—the quantity depending on the quality it is desired to make. The mottling is produced generally by the addition of ultramarine, which gives to the soap a bright appearance.

Some samples, sold at low prices, have come under my notice which have not only been run with silicate but contain from 6 to 8 per cent. of common salt and not more than one quarter of their weight of fatty acids. The salt is of no value as a detergent agent, and must be looked upon simply as a "make weight." It is only with soaps made from palm nut and cocoa nut oil that the salt will combine properly. The peculiar behaviour of these two soaps in salt water renders them valuable for marine purposes. Very considerable experience is required in making a soap of low quality which shall be firm to the touch and present the appearances of a good soap, and the difficulty is increased in the case of common mottled soap, where it is necessary to have the mottling equally distributed throughout the mass. The methods by which this is attained are kept, as a rule, as trade secrets, but no great difficulty is experienced when the matter is approached on scientific principles.

In the common soaps which are usually used for scouring, etc., the proportion of soda in excess of the fatty acids may be greater than in those used for finer purposes or for toilet use. The choice of the fat must also be regulated by the purposes to which the soap is intended to be put.

The details of the manufacture require careful attention and can only be mastered after long experience, but it is necessary that all the processes should be carried on in the lines I have indicated. The peculiar behaviour of each kind of soap would occupy more time than is at my disposal: nor would it serve to elucidate the processes; but it is important that the manufacturer should be conversant with their properties. As a rule, the larger the amount of stearin or palmitin there is in the fat operated upon the harder will be the soap.

Before closing the remarks upon the manufacture I may just refer to two methods which are occasionally resorted to, to improve the appearance of common soaps. The first of these consists in placing the soap in an oven or stove so that it may become surface died and present a hard "skin." The second of these consists in dipping the soap in a strong solution of brine or other liquid. The salt has a great affinity for water and removes it from the surface of the soap, but the soap itself is quite insoluble. This process improves the appearance considerably and prevents the soap having a sticky consistency on the exterior of the bar.

In treating of the second part of my subject, it may be well to preface my remarks with a brief account of the methods by which I have arrived at the results which I propose to state, as showing the quality of the soaps found in the market. I have now in my possession upwards of three hundred analyses of soap from different sources, which have been submitted to me at various times. In analysing these I have found the following processes the most convenient and accurate.

The water is determined by drying in an air-bath a weighed portion of the soap at a temperature of 120° C. At this temperature the soap swells up and the water is soon expelled without any loss of the fatty matters or danger of losing the substance. The weight is taken after about three hours, and subsequent weights are made at intervals of about an hour until the weight is constant.

To obtain the percentage of fatty acids I find it best to weigh out about 3 grams of the soap in a porcelain or platinum basin, including in the weight of the basin a small stirring rod about 3 inches long. The soap is then dissolved in a small quantity of water in the basin, and when *completely* dissolved, about 5 c.c. of dilute sulphuric acid are added. This decomposes the soap, setting free the fatty acids and forming sulphate of soda. The solution is then gently warmed—preferably on a water-bath—until the whole of the fatty acids have risen. It is then allowed to cool, and the fatty matter will usually form a solid cake. If this does not occur a weighed quantity of purified wax must be added and the whole re-melted. When the cake is formed it is simply moved a little from the side, and the liquid from below, which should contain no fat, is poured off. The cake is re-melted with distilled water and allowed to settle as before. This is continued until the washings are free from acid. The cake is then melted in a water oven and again allowed to cool, and the water which still adheres is removed by gently touching with filter paper, and the basin is again placed in the water oven and weighed until the weight is constant. From the figures obtained the percentage of fatty and resinous acids is calculated.

The soda is determined by adding to the filtered solution from a given weight of soap an excess of standard acid and titrating back the excess of acid by means of standard alkali, using cochineal as indicator.

The percentage of silicate is obtained from the silicic acid found. To obtain this I prefer to ignite about 2 grams of the soap in a platinum dish until the volatile matters are dispersed. After cooling, the ash is covered with a glass and treated with an excess of hydrochloric acid. It is then evaporated to dryness, taken up with dilute acid, well washed and then ignited and weighed.

These are the constituents which it is usually necessary to determine, but it is sometimes required to make a more complete analysis. When this is desired it is a good plan to dissolve the soap in alcohol and filter. By this means most of the adulterating materials are separated The chlorine is best estimated after decomposing the soap with nitric acid and allowing the fat to solidify, as in the estimation of fatty acids, by precipitating with nitrate of silver and weighing the resulting chloride.

The percentage of free alkali is important. It can be obtained by precipitating the clear alcoholic solution with carbonic acid, but I prefer to titrate the solution with standard acid, using phenolphthalein as indicator. The results are good.

In making out the analysis of a soap it must be remembered that the fatty constituents actually exist as fatty anhydrides and not as fatty acids, and if, therefore, we determine the whole of the constituents of a soap and include the fatty matters as the estimated acids we shall find that the figures will add up to about 103 per cent. This is due to the absorption of water by the fatty anhydrides in decomposition. The actual percentage of fatty acids should always be placed as a footnote.

In making a choice of the soaps usually found in the market it is difficult to know which to take as representative, but it will perhaps be sufficient to divide them into two classes, the pure and the silicated, and to give a few of the figures which represent the average qualities:—

Pure Soaps.

Mottled	56·91	7·45	3·00	31·41

In conclusion I have to tender my thanks to Mr. Briggs, of the firm of Messrs. Tyson, Richmond and Co., of this city, for kindly supplying me with samples descriptive of the various makes, and for the information and personal kindness he has shown in assisting me in the preparation of this paper.

Proceedings of Scientific Societies.

SCHOOL OF PHARMACY STUDENTS' ASSOCIATION.

A meeting of this Association was held on Thursday, December 20. Mr. T. S. Dymond, Vice-President, in the chair.

After the minutes of the previous meeting had been read and confirmed, Mr. R. W. Giles read a paper on "The Relations of Pharmacy to Therapeutics," of which the following is an abstract:—

The Relations of Pharmacy to Therapeutics.

BY R. W. GILES.

The state of pharmacy in the past was so far from that which a scientific vocation ought to hold that pharmacists were not thought worthy of authority even in matters strictly pharmaceutical. The opinion of the doctor, who was supposed to be a man of science though not a pharmacist, was preferred to that of the pharmacist, who was supposed (with too much reason) not to be a man of science. Even now, although the improvement in pharmacy during the last generation has been great, pharmacists in the mass do not give proof of scientific qualification. The lowest evidence that could be accepted as proof of proficiency in the sciences collateral to pharmacy is the Major examination certificate of this Society; and the number of those who can offer that assurance is probably less than 10 per cent. of those who are engaged in the practice of pharmacy.*

It is not to be wondered at, therefore, that pharmacy, which ought to be treated as a department of therapeutics, had not in the past and has not even now a recognized place in therapeutical science. Or rather, it should be said, pharmacy has of necessity a place in therapeutics, but pharmacists are not yet privileged to be its exponents.

The relation of pharmacy to therapeutics may be viewed in two aspects, viz.:—

1. That of pharmacy collectively.
2. That of individual pharmacists.

The first of these aspects must materially influence the other.

The duties corresponding to the above classification are clearly distinguishable, and may be broadly stated as—

1. Pharmaceutical research.
2. Practical pharmacy.

1. Pharmaceutical research is necessary to therapeutics; and therefore the duty of prosecuting pharmaceutical research must lie *somewhere*. But no one will assert that any individual pharmacist is under the obligation to devote himself to the unremunerative task of research, although many have spontaneously done so. Research is a corporate obligation, in which pharmacists have a common as distinguished from an individual interest. It should therefore be undertaken by the corporate unit, that is by the Pharmaceutical Society.

But what is pharmaceutical research systematically conducted in the common interests of pharmacy? Practically it is the preparation of materials for the Pharmacopœia, which is the final record and application of all pharmaceutical research. The conclusion arrived at may therefore be stated thus:—It is the duty of the Pharmaceutical Society to prepare materials for compiling the Pharmacopœia. It must do this both in fulfilment of the obligation devolving upon it as the accredited representative of pharmacy, and in justification of the claim which it has urged to be admitted to share in the preparation of those formulæ by which all its members are bound. This essential preliminary operation has never been seriously undertaken before, and has never been satisfactorily performed; and, therefore, whenever a new edition of the Pharmacopœia has been called for, it had to be prepared in haste from such materials as could be casually collected from desultory investigations. This was intelligible when the College of Physicians had to do the best they could without any special fitness for the work, but if pharmacists claim to be consulted on the score of special fitness they must prove their claim by using the best means for accomplishing that work creditably on the pharmaceutical side—and obviously that is only to be done by systematic pharmaceutical research. If this course were followed the Pharmacopœia might perhaps present a more enterprising and less conservative aspect than that described by Dr. Redwood, at Southampton, in these words:—"He had no reason to anticipate that in the new edition changes so considerable as those which appeared in the new edition of the American work would be introduced. One principle acted upon in this country was that it was not justifiable to introduce into the Pharmacopœia new preparations which had not been proved in medical practice." If Dr. Redwood had said "new drugs," instead of "new preparations," his assertion would be less remarkable, but if it be not the business of the Pharmacopœia to introduce new preparations, what claim have pharmacists to share in its compilation?

But the duty of the Society must be left to the deliberations of its Council and to the decision of its members; it is not a proper subject for discussion by its students, to whom this outline is presented as a necessary element of the relation of pharmacy to therapeutics.

2. The duty of individual pharmacists is to qualify themselves by preliminary scientific training and by subsequent conscientious practice for the most effective co-operation with the higher branches of the therapeutical profession. The modes in which this may be done are too numerous for citation here. A more advanced pharmacopœia, in which standardized preparations will probably hold a conspicuous place, will demand more scientific knowledge and greater manipulative skill than heretofore. Medical practice, emancipating itself from empiricism, demands from pharmacy greater exactitude. An era of scientific development cannot be a period of sloth for those who would keep pace with it, and it is only by improved scientific attainments assiduously employed in the conduct of his business that the pharmacist will secure that professional status to which the practice of scientific pharmacy fairly entitles him. When therapeutics has accepted pharmacy as its coadjutor in the common ground of the Pharmacopœia, the relations of the

* The last year's summary represented the number of Majors as a little over 11 per cent. of the number of registered chemists and druggists; but as many of these Majors are not in business on their own account, the total must either be compared with the total of those engaged in pharmacy (principals and assistants) or an abatement must be made from the total of Majors for those who are still acting as assistants.

pharmacist to the professor of therapeutics must necessarily be improved, and the medical practitioner will not scorn to avail himself of the former's chemical science in aid of diagnosis. The happiest results should follow from such co-operation.

The changes in the future development of pharmacy will be great without being either sudden or startling; for they will be changes of *development*. Hitherto the changes have been organic, for they have been effected by legislation, to wit, compulsory examination and restriction (although imperfect) of the practice of pharmacy to qualified pharmacists. These have operated in the continental manner, and have so far tended to assimilate English pharmacy to the continental type. That assimilation will probably proceed no further: the continuance of the revolution will be essentially English, accommodating itself to English notions, aiming at the greatest practical convenience and disregardful of theoretic symmetry. In this way the whole of the pharmacies throughout the country will gradually follow the lead of the best English examples—they will become fewer in number and will shake themselves free from incongruous traffic, which neither needs nor suits a man trained to scientific pursuits. Yet they will not discontinue the traffic in the numerous articles which are accessory to though not strictly included in pure pharmacy; and pharmacists will continue to hold an intermediate place between the trades and the professions, discharging the functions of the one and possessing the recognized qualifications of the other.

As the result of these conditions they will attain to the status which an educated and scientific body must always enjoy; forming an integral part of the profession of therapeutics, occupying, indeed, a lower position therein than the medical members, but though inferior in professional status not necessarily inferior in scientific attainments.

Backed by the *prestige* of a profession that gives assurance of respectable scientific education, the pharmacist will no longer be excluded from asserting whatever scientific standing his personal qualifications enable him to maintain; and the grievance now felt by exceptional men (allusion to which on a former occasion suggested this discourse) will cease when such men cease to be exceptional.

A long discussion followed, in which the Chairman, Secretary, Mr. Joseph Ince and Mr. R. H. Parker took part. After Mr. Giles had replied, Mr. Baily proposed and Mr. Ranken seconded a vote of thanks to Mr. Giles for his interesting and suggestive paper, which was carried unanimously.

The Secretary then read the following note on "Munjeet in Chiretta," by the Reporter on Materia Medica.

Munjeet Stems in Chiretta,

BY WILLIAM ELBORNE,

Assistant Lecturer in Materia Medica and Pharmacy, and Curator of the Materia Medica Museum, Owens College.

About two months since, among other donations to our museum, I received from Messrs. Woolley and Sons an original bundle of a plant labelled "Roots found in Chiretta."

Owing to its being neatly folded and corresponding in size to an original bundle of chiretta, its physical resemblance to the true drug induced me to examine it more closely. On breaking the package open I observed that it consisted essentially of long slender *stems* divested (naturally) of the external bark, with the remains of a few leaves. I also noticed that towards the apices, where the outer bark remained attached, the stems were rendered square, whereas the stems where denuded were distinctly round, about the thickness of a quill, and of a dull red colour.

From these characteristics I readily discerned that the plant was not that of any species of *Ophelia*, and consequently not the false chiretta of Bentley.*

However, on referring to the Professor's paper I came across the following passage:—"Moreover, beyond the case of false packing described by Mr. E. A. Webb,† in which the roots of *Rubia cordifolia*, Linn. (Munjeet), had been *enclosed* in bundles of chiretta, I know of no published case of adulteration or substitution of the true chiretta in this country."

From the red fracture of the stems in question I had already imagined they were those of some species of *Rubia*, and the above remarks afforded me a clue to the matter. Referring to Mr. Webb's paper, I found that my specimen corresponded exactly with his description, with the exception of the roots being altogether absent.

I thereupon submitted a portion to Mr. E. M. Holmes to compare with specimens in the Museum of the Pharmaceutical Society, who referred it to *Rubia cordifolia*; and obtained authentic specimens from Kew, with which they entirely agreed. Thirteen years having elapsed since the case of "false packing" was recorded by Mr. Webb; its re-occurence will, I think, justify its again being brought under notice, lest the falsification be more frequent than brought to light. Previous to stating the essential characters whereby the stems of *R. cordifolia* may be distinguished from the true drug, I might allude to the fact that the plant is extensively cultivated in India on account of its roots, which when grown constitute Indian madder (European or genuine madder being derived from the roots of *R. tinctoria*), forming a very important article of export over the Himalayas to Thibet, where great quantities are consumed in dyeing the garments of the Shamas: consequently, it is not surprising that the Indian cultivators, finding their refuse stems somewhat resemble chiretta in appearance, should endeavour occasionally to turn them to some profitable account.

The following constitute the leading distinguishing characters botanically:—

Rubia corifoli a.	*Ophelia chiretta.*
Stem.—Long, trailing, outer bark mainly absent; stems on that account round and of a dull red colour. When the outer bark remains attached (at apex), quadrangular, covered with minutest prickles at the angles. Fracture, red. Pith, absent.	*Stem.* — Erect, smooth. Fracture, white, with shrunken pith.
Leaves. — Lamina about 1 inch in length, obcordolanceolate, five ribbed, ribs armed with prickles; supported on long petioles, arranged in whorls of four at the nodes, the latter very conspicuous.	*Leaves.*—Sessile.

Examined microscopically the internal structure of each is so marked that a glance will suffice to distinguish them. In the section of *R. cordifolia* it will, however, be noticed that the woody tissue is more abundant, permeated with very large vessels, and coloured throughout with red matter.

While writing I have been informed by Mr. F. C. Bird that several more bundles have been discovered in other bales. Chiretta being a drug generally supplied to pharmacists in the cut state, this tends, I imagine, to facilitate small quantities of such impurities escaping notice. The infusion and tincture yielded by *R. cordifolia* are, however, of a port wine colour as compared with those of chiretta, which are sherry-coloured.

In conclusion, I beg to acknowledge the services of the authorities at Kew, and those of Mr. E. M. Holmes, Mr. Kirby, and also of Mr. Hermann Woolley, who first detected the adulteration.

---

* *Pharm. Journ.*, [3], v., 481.
† *Pharm. Journ.*, [3], i., 367.

Photographs of sections of *Ophelia chiretta* and *Rubia cordifolia*, as well as specimens of the drugs themselves, were exhibited.

After a short discussion upon this Report, the Secretary reported that the revised rules of the Association had been approved by the Council of the Pharmaceutical Society, and would therefore take effect during the present session.

Parliamentary and Law Proceedings.

Poisoning by Almond Flavouring.

Mr. J. C. Malcolm, the Leeds Borough Coroner, held an inquiry, on Dec. 14, 1883, into the death of Elizabeth Heselwood, who had been an inmate of a private asylum at Acomb, near York, and who returned to her family occasionally. She came home, after several months' absence, under the care of a nurse. All went well until the night of the 14th of December, when Mrs. Heselwood, who had been in unusually high spirits that day, was found dead in bed shortly after twelve o'clock. By her side was a small bottle, which had contained almond flavouring, but which was then empty.

Mr. Stacey, surgeon, who was called in, said that death had been caused by the flavouring, 2 drachms of which would be sufficient to poison a man.

Mr. Heselwood stated that on five or six different occasions his wife had attempted to commit suicide.

The Jury found that the unfortunate lady had committed suicide whilst of unsound mind. They were convinced that every care had been taken of her, and expressed their sympathy with Mr. Heselwood.

The Explosion of a Mixture.

On Wednesday, December 26, 1883, the adjourned inquiry into the circumstances attending the death of William Turley, who died in the Manchester Royal Eye Hospital, whither he had been removed from Warrington, was held before Mr. Sydney Smelt, the City Deputy coroner. It will be remembered that deceased purchased small quantities of aquafortis and quicksilver, which were mixed in one bottle and served to him by Mr. Woods, chemist; that deceased placed the bottle in his breast pocket, and that while walking home the bottle exploded and the contents seriously burnt his eyes and face.

G. Harry Nichol said he was an assistant to Mr. Woods and remembered the deceased coming for the two ingredients named. His master did not say, in reply to a question from the deceased, that the stuff would be all right or safe in the bottle. Mr. Woods had himself cautioned deceased as to the dangerous character of the drugs, but only on the first occasion, when deceased made his first purchase at the shop.

James Forster, a butcher in the employ of Mr. Gill, of Warrington, said he saw the explosion. The cork "flew" out of the bottle, and the contents were blown in the face of the deceased just as he reached his master's shop door. Deceased asked for water, which witness procured, and afterwards assisted him into a neighbouring chemist's shop.

Mr. A. H. Griffiths, house-surgeon at the Manchester Eye Hospital, said if deceased had recovered, one eye would have been blind, and the other injured. From the *post-mortem* examination of the deceased he found that the cause of death was collapse, brought on by diarrhœa, which resulted from ulceration of the bowels, and though the burns might have caused the ulceration he could not tell whether such had been the cause or not. Deceased was not a very strong man.

The Coroner having carefully summed up, the jury retired, and on their return the foreman said they were not satisfied that death had been caused by the burns. They were, however, satisfied that Mr. Woods, the chemist, had been guilty of negligence, but thought a censure from the Coroner would meet the case.

Mr. Smelt said he quite agreed with the jury. No one who had heard the evidence could doubt that Mr. Woods, being a member of the Pharmaceutical Society, had been guilty of negligence in mixing the two ingredients and giving them to the deceased in a corked bottle.

The formal censure having been given, a verdict was entered to the effect that deceased died from collapse caused by ulceration of the bowels.—*Manchester Courier.*

Poisoning by Carbolic Acid.

On Monday, Mr. William Carter, Coroner for East Surrey, held an inquiry at St. Thomas's Hospital, respecting the death of John Thomas Denton, aged 26 years, an auctioneer's clerk, who was to have been married on Christmas morning, but who was discovered in an insensible condition with a bottle labelled "Poison" by his side, while the bride and friends were awaiting his arrival at the church. The deceased afterwards tried to speak, but could not. The bottle was labelled as having come from Messrs. Brooks and Hadwin, surgeons, Waterloo Road, but the writing on the label had been rubbed out. A witness then took the bottle to Brooks and Hadwin's to ascertain what it had contained and was informed that it had contained a poisonous liquid, and Mr. Hadwin advised that the deceased should be taken to the hospital, whither he was conveyed i a cab.

Mr. Arthur Foxwell, house physician, deposed to receiving the deceased on his admission in an unconscious state, breathing stertorously, and with livid features. Witness attempted to administer an antidote, but could not. A bottle was shown to witness, which contained a small portion of carbolic acid. The deceased became worse and died about 2 o'clock the same day from the effects of poison.

Further evidence having been adduced, the Jury returned a verdict of "Suicide while in a state of temporary insanity."—*Times.*

Poisoning by a Patent Medicine.

The Coroner for Central Middlesex, Dr. G. Danford Thomas, held an inquiry on Monday at Paddington, as to the death of William Henry John Heath Shehan, aged seven months, which was alleged to have resulted from the administration of a patent medicine sold as a specific for whooping-cough.

William Francis Heath Shehan, 23, Marylands Road, Paddington, said deceased was his child. It had been brought up by hand owing to the death of its mother, and had been suffering about a month from whooping cough. He had given it a patent medicine called "Holt's specific," as many persons had recommended it, and a child in the same house, aged one year and nine months, was also taking it.

Martha Wilkinson, residing in the same house, said she took charge of the child on the death of its mother. She had given the child five doses of the "specific" altogether, the dose being one teaspoonful every four hours. She gave the doses regularly. On Wednesday night she put the child in its bassinet, and on Thursday morning, about 8 o'clock, she found it dead. She had intended to send for a doctor that morning, as its breath had been short all day on Wednesday. She expected the medicine to make the child sick, and it did so the first dose.

Dr. Finzi, who was sent for shortly before 9 a.m. on Thursday, said the child had been dead about an hour. There were no signs of suffocation. He had made a *post-mortem* examination and found the lungs healthy, but with the air-cells enlarged. There were patches of inflammation in the stomach and intestines which had been caused before death, which was due to failure of the heart from poisoning by antimony when suffering from whooping cough. He had analysed the specific, and found it contained antimony which would have the effect of creating excessive vomiting, depressing the heart's action, and irritating the stomach and intestines.

The Coroner: Now, taking into consideration the number of doses administered to the child and the quantity taken in each of those doses, do you consider the antimony had any share in causing the death?

Witness: Yes.

The Jury remarked that the Government ought to interpose to prevent the sale of these patent medicines, which were simply poisonous rubbish.

The Coroner concurred, but said under the existing law there was no mode of stopping the sale of these dangerous medicines. Persons could take out patents without being compelled to state the ingredients, which they kept a secret. In France the case was different. The law compelled a statement to be made outside the vessel what the contents consisted of. Such a law was required here to protect the public.

Dr. J. E. Curgenven, Craven Hill Gardens, deposed, in obedience to the coroner's warrant, that he had assisted Dr. Finzi in the *post-mortem*, and corroborated his evidence. There was half a grain of antimony in each dose. The witness added he had seen two children suffering lately from the effects of the same medicine. One had died, and an inquest was held on it; the other had its heart so enfeebled that he had been obliged to administer brandy to it, and it was now recovering. This specific was vended by a lady who kept a confectioner's shop, who did not, he supposed, know the effects of antimony.

The Coroner supposed the "secret" had been handed down to her, as the handbill advertising it said it had been established eighty years.

Dr. Curgenven then described the effects of antimony, and said that the deceased was healthy and well-nourished. There were no traces of disease in the lungs, and it would have lived had it not been for the administration of the antimony. No doubt the death had resulted from the effects of antimony contained in the preparation called "Holt's Whooping-cough Specific."

The Coroner here remarked that on the previous inquest held by him a fortnight since, the proprietress of this "Holt's specific" attended with her solicitor, but made no comments. It was strange, however, that neither of them were present on this occasion.

The Jury, having consulted for some time, returned the following special verdict:—"That the deceased had died from syncope through failure of the heart's action when suffering from whooping-cough; and the said jurors are further of opinion that the said death was accelerated by the administration of antimony contained in a mixture called 'Holt's Specific for Whooping-cough,' and the jurors desire to call the attention of the Home Secretary to the want of protection to the public in the sale of patent medicines, with a view to some legislation restricting the sale of those containing poisons and other dangerous remedies."—*Times*.

THE POISONOUS PROPERTIES OF RHODODENDRON PONTICUM.

Sir,—On reading the paragraphs in "The Month," in the Journal of December 29, relating to the queried poisonous properties of honey from the flowers of *Rhododendron ponticum*, and of the leaves of the same, I thought, as I was in possession of some facts bearing on the question, I would send them to you. In December, 1882, I was consulted as to the cause of death of some twenty sheep in this neighbourhood, suspected to have been poisoned. I had one of them brought to me entire and removed the paunch, which was much distended. In this I found, besides hay or grass, a considerable quantity of half-chewed leaves which I had no difficulty in identifying as those of the rhododendron. This was then confirmed by finding tracks of the sheep in the snow to a bed of rhododendrons in the park, which showed that they had been bitten and eaten. I was informed that the sheep rolled and staggered about before death, as if drunk. The veterinary surgeon who had charge of the case gave me at the time the medical particulars of the affection and the *post-mortem* appearances. I cannot now state them accurately, but could get them if required. My object is just to place on record what appears to me to be a very clear and decisive case of the poisonous action of *Rhododendron ponticum*, and it is the more important that this should be known, as the planting of this shrub and its hybrids in parks, etc., has much increased of late years.

Bradford. ROBT. PARKINSON.

"*Justitia*."—We do not remember having made such a statement. Your proper course would be to apply for the information to the Dean of the medical school you propose to enter.

R. Shenstone.—As to the dispensing of potassium permanganate pills see the references in the index to the last volume of this Journal.

J. A. L.—We have not heard that the work referred to has yet been published; neither are we acquainted with one of the same nature.

Query.—We do not believe there is such a work.

A. Wrighton.—The first of the Cantor Lectures on the Scientific Basis of Cockery was published in the Journal of the Society of Arts for December 29.

Inquirer.—The common sundew (*Drosera rotundifolia*) and other members of the Droseraceæ. See Darwin's 'Insectivorous Plants.'

M. M.—(1) The hypnotic and anodyne action of codeine is relatively slight (see *Pharm. Journ.*, [3], iv., 88). (2) 'Pharmacographia.'

"*Cryptogamic*."—(1) We do not think the book mentioned alone would quite suffice for the purpose. (2) We are not acquainted with the work.

Inquirer.—A list of the certificates accepted in lieu of the Preliminary examination is published in the Society's Calendar.

J. Straphey.—A candidate for the Minor examination must be of the full age of twenty-one years, and must also have passed the Preliminary examination or an accepted equivalent.

COMMUNICATIONS, LETTERS, etc., have been received from Messrs. Wilkinson, Whitla, Möller, Tyrer, Bennett, Torkington, Harris and Co., Samuel, Druggist.

THE OCCURRENCE OF SUGAR IN TOBACCO.

BY PROFESSOR ATTFIELD, F.R.S.

About a year ago the following questions were put to me, "Does tobacco contain sugar or any similar saccharoid matter? if so, how much?" The subject not previously having come before me I could not definitely reply. Indeed, a search through the literature of tobacco showed that the questions could not satisfactorily be answered at all in the existing state of our knowledge. I therefore proceeded to obtain evidence on the matter by direct chemical investigation. Samples of cut and uncut tobacco were obtained and tested for sugar by the copper test, the fermentation method, and the polariscope. The copper test not yielding concordant results was discarded: it is a good test under most circumstances, but for the quantitative estimation of sugar in tobacco infusions, or, probably in similar vegetable infusions and decoctions, it appears to be untrustworthy. The examination of tobacco infusion by the polariscope will be referred to subsequently.

All the samples readily yielded alcohol when properly fermented with yeast; hence all, presumably, contained sugar, the amount varying from 4 to 9 per cent. But as they were obtained from ordinary trade sources, and as tobacco has been known to have molasses, honey, and other varieties of sugar mixed with it, the samples obviously might contain sugar, and yet sugar not be a natural constituent of tobacco. I therefore proceeded to examine specimens obtained from museums and one which had been raised in my own garden during the previous summer. The latter contained only traces of sugar; but it had been grown in the open, at anything but a tropical temperature, and was not, I think, ordinary Virginian tobacco, but rather the Maryland variety. I may even state, here, that a sample grown in my garden last summer, under better conditions of sunlight, with more care, and from which the flowering tops were frequently nipped off to promote development in the leaves, furnished less than two per cent. of saccharoid matter. Of the other samples some did and some did not afford evidence of the presence of sugar. A specimen of old dark coloured Indian leaf gave no sugar, a light coloured Indian leaf yielded 1·54 per cent., calculated as cane sugar. A bundle of leaves marked "Original sample as drawn from dock at Liverpool," furnished 10·84 per cent. These results being unsatisfactory, for my purpose, I at once asked six or eight of my chemical and pharmaceutical friends, residing in different parts of the great tobacco-producing States of America, namely, Virginia, Kentucky, and North Carolina, to obtain for me authentic samples of genuine tobacco. Each correspondent, kindly, at once, acceded to my request. Neither was in any way connected with the tobacco interest, each resided many miles from the rest, and neither of my friends knew that others were simultaneously collecting samples for me.

While waiting for these authentic samples of American tobacco leaves I ascertained that such precipitants as basic acetate of lead and lime water would remove, from tobacco infusions, alcohol-yielding material, equivalent, on the average, to about 3 per cent. of the tobacco. The saccharoid matter not thus separated may be termed *tobacco sugar*; while this, together with the fermentible matter precipitated by the reagents named, may be termed *total saccharoid matter.*

The samples from the United States duly reached me. They yielded the following results:—

	In 100 parts of tobacco leaf. Tobacco sugar.	Total saccharoid matter.
A	7·00	9·87
B	5·57	8·61
C	7·76	10·94
D	9·60	12·80
E	7·43	10·20
F	9·29	12·40
G	5·57	8·23
H	6·81	10·10
Average	7·38	10·39

The inference is obvious, namely, that tobacco does contain sugar, the amount varying from mere traces, in tobacco grown under conditions not favourable for the production of sugar within the plant, up to nearly 10 per cent., or possibly more, in the light coloured or bright Virginian leaf. I say that, bearing in mind the origin and the results of the analyses of these specimens, their sugar, or fermentible saccharoid matter, is natural; unless we make the absurd assumption that amongst tobacco growers there exists a secret yet apparently universally enforced convention for saturating tobacco plants with a solution of a special and elsewhere unknown variety of sugar.

In cases of suspected sophistication the fermentation method of analysis would probably be adopted, and then as much as 13 per cent. of natural saccharoid matter, or possibly more, might be obtained from tobacco. I myself have examined a large number of commercial samples of tobacco, both uncut leaf and cut, in the form especially of cigarettes, and I have obtained by this method percentages of saccharoid matter varying from 4 to 12½. Even a specimen of a popular dark coloured tobacco, specially fermented to develop highly prized odours and flavours, but which, as chemists would expect, had probably lost much of its sugar during the process, yielded 3 per cent. of tobacco sugar and 5¼ per cent. of total saccharoid matter. It will be seen that the greatest yield of sugar from the trade samples is less than the maximum from my standard samples of genuine tobacco. The average yields of the two sets were very close, both being very near to 10½ per cent. The results indicated, therefore, that the trade samples did not contain added sugar.

If a sample of tobacco contained added sugar its percentage of matter soluble in water would also be raised, and the proportion of matter insoluble in water *pro tanto* be reduced. My authentic samples yielded from 32 to 37½ per cent. of insoluble matter, the average being 35·7. One set of commercial samples yielded an average of 35·9 per cent. of insoluble matter; the assumption of any systematic sophistication of these by sugar was, therefore, again negatived.

The sugar in tobacco appears to possess little, if any, action on polarized light. Such a fact would be of considerable importance in any examination of tobacco infusion for added sugar,—sucrose, glucose, lactose, etc.,—which all exert well-marked dextro-rotatory or lævo-rotatory power on polarized light. The commercial samples of tobacco I have myself recently examined, with scarcely an exception, yielded infusions which, even when colourless, did not perceptibly affect a polarized ray; therefore, with a bare exception they were unadulterated by sugar. Certainly samples forwarded to me by officials of the Customs in London, at the request of owners, did not contain added sugar. But the fact has, also, theoretical importance, for the existence of a *tabacose*, as we may term it, if it is a true sugar, having such properties, would point to the existence of a sub-class of fermentible but non-rotatory sugars. Possibly, however, the action of this fermentible substance on a polarized ray is only masked.

The isolation and complete chemical and physical investigation of the saccharoid principle or principles in tobacco remain to be accomplished. I should myself proceed with this work, but am assured by a friend that he has already commenced and intends to complete and to publish the results of such a research.

I have to thank the following gentleman for supplying me with specimens:—Mr. T. Roberts Baker, Richmond, Virginia; Mr. C. Lewis Diehl, Louisville, Kentucky; Mr. Marshall C. Hall, Fredericksburg; Mr. F. H. Masi, Norfolk, Virginia; Messrs. Charles F. Tag and Son, New York; two friends in Danville and Lynchburg; Mr. E. M. Holmes,; and the representatives in England of Messrs. Goodwin and Co., Messrs. Allen and Ginter and Messrs. Kimball and Co. Messrs. Stillwell and Gladding have also been good enough to furnish me with information respecting the non-saccharoid principles of tobacco.

CANADIAN INDIAN REMEDIES.

In the course of a lecture on Canada and its Products, delivered by the Marquis of Lorne before the Society of Arts on the 19th ult., he said:—

"Much is said of the knowledge possessed by the squaws of simples; it is certain that they are very clever in producing decoctions and in making poultices from various trees and shrubs whose healing properties are well known to science. Thus, from the bark of a certain species of willow, a preparation can be made which stanches hemorrhage, and quickly heals a wound. Strange tales were told us of the efficacy of some of their medicines. A gentleman employed in botanical research was puzzled by an application made to a slight wound he had sustained; he had, when shooting, hurt his thumb by the accidental discharge of his gun, and for some days, having nothing but water with which to bathe it, he was in considerable pain, and the thumb became much inflamed. Lighting one day, in the course of his march, on a camp of Sioux Indians, one of the women observed his hurt; she came to him and gave him a milk-like liquid, and told to apply this when he felt pain; he did so, and from the first application the pain ceased, and in a few days a very complete cure was effected. A sergeant in the Mounted Police was an eye-witness of the effects of an opiate given to a man, for whom the ordinary remedies of opium, laudanum, and chlorodyne had proved useless. It was evident that the medicine man had some good stuff, although it was equally certain that he employed a great deal of what is known as *hocus pocus* in applying it. He asked for a vessel, and after a time poured into it a white liquid he had concocted. He then covered this vessel over with a skin, pierced holes in the covering, rolled up some pellets of buffalo hair in his hand, muttered some pretended incantations, and dropped these balls of hair through the skin into the liquid. After a while, the covering was removed, and it was seen that the vessel held no longer a white but a red liquor. This, with an amount of faith which one does not often find in a sick patient, was drained by the invalid, and a sound sleep, which was the beginning of a perfect recovery from the illness, appeared to be the result. There may be something worth discovering in the application made by the Indians of certain herbs; but it is to be noticed that the roots and plants hitherto found in the medicine man's lodge have, as a rule, been plants whose properties are already well known to science."

THE SALE OF POISONS IN IRELAND.—DEPUTATION TO THE CHIEF SECRETARY.

On Tuesday last a deputation from the Pharmaceutical Society of Ireland waited on the Chief Secretary, at the Castle, to draw attention to some of the defects in the Pharmacy Act of 1875, and to suggest certain amendments. The deputation consisted of Messrs. James E. Brunker, M.A., President; Harry Napier Draper, F.C.S., Vice-President; Drs. Allen, Collins, Grindley, Hayes, Hodgson, Montgomery, and Mr. Simpson. Mr. Hugh James Fennell, Registrar to the Society, accompanied the deputation.

Mr. Brunker said the object of the deputation in waiting on the Chief Secretary was to call his attention to the state of the law regulating the sale of poisons in Ireland. In the greater part of Ireland, at present, the Sale of Poisons Act was a dead letter. In small country towns and villages they were sold by hucksters, stationers, ironmongers, grocers and others. In England, up to the passing of the Act of 1868, there had been absolutely free trade in the sale of poisons and medicines. When that Act was passed it was provided that persons who at the time were actually carrying on business in that way should be allowed to continue it, but that they should be registered—without any qualification. In Ireland the position of chemist and druggist was different. Until the passing of the Act of 1875 they had the right of retailing poisons, but had not the right to compound medicines. Such chemists and druggists as were in existence at the time were allowed to continue in business. They were obliged to pass an examination but were not obliged to register. By section 31 of the Act such persons had reserved to them the right to continue to sell poisons without any examination, but no machinery was adopted whereby such persons should be registered. The Pharmaceutical Society had no power to register them—they did not know who they were; and others, besides those in business in 1875, were cropping up every day. For the protection of society, it was desirable that there should be a power given to them of registering those persons. The question was whether such a grade of men should be allowed to continue. There was some difference of opinion, but the Council, by a majority, thought that it would be in the interest of the public that in future all persons should be licensed to sell poisons only on passing a moderate examination. These it was proposed to call "registered druggists."

The Chief Secretary: Would the registered druggist be allowed to compound medicines?

Mr. Brunker said he would not. They felt, however, that at the rate at which men were coming up to them at the present time it would be many years before they could supply the wants of the public in small towns and country villages. The Council also recommended that patent medicines containing poison should have that fact and the amount of the poison printed on the label or wrapper. They also desired certain words in the Act to be made more specific to prevent what at present existed—namely, that a qualified man and an unqualified man could carry on business jointly, while, of course, an unqualified man could not carry on business alone.

The Chief Secretary: Before the passing of the Act of 1875, no one could compound medicines in Ireland except apothecaries.

Dr. Collins said that in England up to 1868, any man was at liberty to compound medicines. They generally served an apprenticeship, but there was no law requiring them to do so. In Ireland, for centuries, the compounding of medicines was confined to licentiates of the Apothecaries' Hall. In 1830 the various medical colleges found it necessary to extend their curriculum.

The Chief Secretary: Do I understand you to say that before 1875 there was no shop in Dublin where medicines could be compounded, except at an apothecary's?

Dr. Collins: There was not legally. There were a considerable number of persons who acted illegally, and we were obliged to prosecute them. The Pharmaceutical Society, while considering that it would be undesirable to have two grades of pharmaceutical chemists, yet recognized the inconvenience it would be for farmers to have to send a great distance for cattle and other medicines.

The Chief Secretary: Do you propose registration of these in business at the date of the Act or those now in business?

Dr. Collins said they considered the registration should date from 1875, as a large number of persons had sprung up since then who had no real knowledge.

The Chief Secretary: How many licentiates of the Pharmaceutical Society are there at present?

Mr. Brunker: Two hundred and forty.

The Chief Secretary: Of these how many are pharmaceutical chemists, and how many apothecaries?

Dr. Collins said all these had passed the examinatiou, but they had located themselves in the large towns: they would not go to the small places.

The Chief Secretary: What is the average number of certificates yearly?

Mr. Brunker: The year before last it was fifteen; last year it was nineteen. This year it is somewhat more.

The Chief Secretary: Where, then, does the main supply of medicines come from?

Mr. Brunker: From the old apothecaries who are rapidly dying out.

The Chief Secretary: Are you disappointed with the results of the Act of 1875?

Dr. Collins said that the first year was a year of grace. They allowed all chemists and druggists who could pass a reasonable examination to come up for examination. They had now a literary examination, and four years' apprenticeship, and then a final medical examination. He expected that after a few years a larger number of young men would present themselves.

The Chief Secretary: Are there a large number of young men serving as apprentices?

Mr. Brunker said that about three hundred had passed the preliminary examination. In answer to the Chief Secretary's question he would say that they were very much disappointed with the results of the Act. He thought this was very much to be accounted for by the want of technical schools in Ireland.

Dr. Collins: Three hundred and twenty-one young men had actually passed the preliminary examination. Only sixty-four out of these had yet passed the final examination.

The Chief Secretary: Is the literary examination at the commencement?

Dr. Collins: It is. We made that a *sine quâ non.*

The Chief Secretary: Would the registered druggists be able to sell patent medicines?

Mr. Brunker said that at present there was no restriction on the sale of patent medicines either in England or Ireland.

The Chief Secretary: Is the sale of patent medicines greater in Ireland than in England?

Mr. Brunker: No; very much less. The lower classes are almost entirely supplied with medicines from the dispensary medical officer. The Irish people, too, are not the medicine-taking people that the people of England are. As a rule the Irish people only take medicine on prescription.

The Chief Secretary asked what was the practical state of things in England?

Mr. Brunker said that in England every village almost had its qualified man. There was a glut of qualified men, whereas in Ireland there was a paucity.

The Chief Secretary said that what the deputation had put before him presented itself undoubtedly in a very reasonable form. If once, however, the question of amending the Act was started, there might be proposals from other quarters, and it might save time if other matters that might lead to controversy should be discussed also beforehand. With regard to the Bill of 1875—by whom was it introduced?

Mr. Brunker: By the Government.

The Chief Secretary: From the first?

Mr. Brunker: From the first.

The Chief Secretary said he had heard their representations with the greatest respect, and he should not hesitate to speak out if from the information that they had laid before him he saw any decided objection to the amendments they proposed. He could, however, do very little more than recognize the force of their arguments, and promise, unless he heard any counter-arguments which might appear of sufficient weight, to do all in his power to meet their wishes. There would be, no doubt, sufficient publicity given to what had passed in that room to-day to enable any counter statements to be brought forward, and these he should consider as carefully as he had heard their statement that day. It was quite impossible to bring forward any opposed bill on Irish matters early in the session with any chance whatever of its passing, because in the first place there would, no doubt, be important Government measures not relating to Ireland brought forward, and one could hardly hope that these would pass without a certain amount of controversy; and, in the next place, undoubtedly he had pledged the Irish Government, as far as a pledge could be given, to one or two measures—to one which would undoubtedly be opposed—he referred to the Sunday Closing Bill—and to another which, if not opposed, would at all events give rise to a good deal of comment and interesting debate. If, therefore, there was any serious opposition to this measure, he could not give a promise of its being carried at an early period of the session. There would, therefore, be plenty of time for them to consider the matter, to look for the minor details, and for those who might be opposed to it to bring their arguments against it.

The deputation then retired.

THE PUBLIC PRESS ON THE SALE OF PATENT MEDICINES CONTAINING POISONS.

From the British Medical Journal, *Jan.* 5.

. . . "Whatever good may result from the occasional use of quack remedies—and it is probable that good does occasionally arise from their use—the indiscriminate taking of secret nostrums by an ignorant public, for all sorts of purposes, is a most pernicious habit. We have been led to make these remarks . . . for the purpose of drawing attention to an inquest, held by the Coroner for Central Middlesex, reported in the daily papers of January 1. A child, seven months of age, and brought up by hand, was suffering from whooping-cough. For its relief 'Holt's specific' for that disease, formerly called 'Hooper's,' was given in teaspoonful doses every four hours. After the fifth dose the child succumbed, and no wonder, for, according to the evidence of Mr. Finzi, who made a necropsy and an analysis of the medicine, each dose of this contained half a grain of tartar emetic. There were patches of inflammation in the stomach and intestines, and death was due to failure of the heart, from poisoning by antimony, when suffering from whooping-cough. The jury, on this evidence, remarked that the Government ought to interpose to prevent the sale of these medicines, which were simply poisonous rubbish. The coroner stated that under the existing law there was no mode of stopping the sale of these dangerous medicines. Mr. Curgenven also gave evidence to the effect that he had seen two children suffering, lately, from the effects of the same medicine; one had died, and an inquest had been held, and the other had a narrow escape. The deadly 'specific' was vended by a woman who kept a confectioner's shop. The jury returned the following verdict:—'That the deceased had died from syncope through failure of the heart's action, when suffering from whooping-cough; and the said jurors are further of opinion that the said death was accelerated by the administration of antimony contained in a mixture called 'Holt's specific for whooping-cough,' and the jurors desire to call the attention of the Home Secretary to the want of protection to the public, in the sale of patent medicines, with a view to some legislation restricting the sale of those containing poisons and other dangerous remedies.' Speaking with some knowledge of these patent medicines, we have no hesitation in stating that we believe there is annually a large loss of life from their use. No inconsiderable number of these containing tartar emetic as a constituent. We have now before us a pink powder nearly entirely composed of tartar emetic, advertised and sold as a cure for dipsomania. Its use for this purpose must be attended with extreme danger."

From the MORNING POST, *Jan.* 3.

"Patent medicines sold by confectioners and grocers, and swallowed by persons of all ages and constitutions, should, as their most essential characteristic, be perfectly harmless; indeed, looking at the sad results frequently ensuing from these preparations, it must appear that the nearer these ingredients approach the famous bread pill and coloured water draught the better for those who take them. With culpable recklessness, however, powerful and even poisonous drugs are at present employed in patent mixtures, whose effects too often supply occasion for coroners' inquests. An instance of this kind has just occurred in Paddington, where an infant died in twenty-four hours from irritant poisoning, produced by a much-advertised 'specific for whooping-cough.' The medicine was purchased from a small sweet shop and administered in due quantities and at the prescribed times, but five doses proved sufficient to end the existence of a child after intense suffering. Medical testimony attributed the death to antimony, and analysis of the 'specific' showed that each dose contained ½ a grain of that poison. It was stated that an inquest uuder precisely similar circumstances was held in the same district, a fortnight ago, whilst numerous cases have occurred there of children rescued with difficulty from the fatal effects of the same potion. In returning a special verdict the jury stated their desire to call the attention of the Home Secretary to the want of protection afforded to the public in the sale of patent medicines, with a view to legislation forbidding the sale of those containing dangerous ingredients. It is matter for regret that the Patents Act, which has just come into operation, contains no provision dealing with this matter; but it is to be hoped the omission will be remedied and the patentees of medicinal specifics be no longer permitted to manufacture poisonous preparations of which the contents are undisclosed, and scatter them broadcast amongst the community with apparently entire irresponsibility. The plan adopted in France of requiring those who obtain patents for medicines to make a statement of the materials to be used; and, further, to declare on each vial or packet the nature of the contents might advantageously be adopted in this country, but would not meet the entire difficulty. Much of the peril and harm arises from the increasing practice of selling these drugs in conjunction with groceries and confectionery by shopkeepers as utterly unacquainted with the names and properties of chemical substances as their most ignorant customers. In vain would the significant word antimony be inscribed on the remedy for whooping-cough, or the deleterious compounds of various favoured narcotics for adults be openly proclaimed, and the only true protection for the public consists in depriving this class of persons of the right of selling them. Anything in the nature of drugs should be procurable only from chemists, whose knowledge and discretion would guide them in dispensing, and they should be made acquainted with the materials entering into the composition of the patent medicines which they sell. All these preparations cannot be classified as deleterious or worthless. Many are prepared from the prescriptions of men of high medical attainments. Others have stood the test of public trial for a great number of years. Without exception, however, the good, bad, and indifferent, down to the penny packets of vermin killer, should be swept from the shelves of ordinary tradesmen. When chemists become their sole legal vendors there will be a perceptible decrease both in the number of lives accidentally sacrificed and of those purposely destroyed through the agency of these preparations."

From the KENSINGTON NEWS, *Jan.* 5.

"A case of poisoning at Shepherd's Bush by hydrochloric acid, another case at Chelsea of poisoning by lobelia, and two recent cases of dog-poisoning, again draw our attention to the scandalous manner in which poisonous substances are permitted to be sold. It would be ridiculous to attempt to prohibit the sale of poisons; they are constantly employed in the arts and manufactures, as components in patent medicines, and as ingredients in rat-killers and the like. But the regulations under which they are sold are stupidly insufficient. The kind of shop at which the poison is bought ought to make no difference whatever; and it is quite immaterial whether it is sold as such, or as an ingredient in a mixture, paste, or other compound. So long as the quantity sold is sufficient to kill, the same measures ought to be required as if it had been bought from a chemist, and in a separate and undisguised form. Cyanide of potassium, for instance, is composed of potass and prussic acid. A chemist is not permitted to sell it except under certain provisions, but anyone who chooses can obtain it at a photographic material shop without question asked or answered. Hydrochloric acid, again, is a strongly corrosive substance, and, because of its smell and taste, no rational person would be likely to take it in mistake for medicine; but it is used for cleaning metals because of its very corrosiveness, and it would be as much out of the question to stop its sale, as it would be to put an embargo on photography by prohibiting the sale of cyanide of potassium. Green copperas, again, and most other disinfectants, are poisonous; but no sane man would think of arresting its sale, any more than arresting the sale of the powders used for making sheep-wash, or of creasote, carbolic acid, or other poisonous chemicals. Rat poisons, whether strychnine or phosphorus paste, and patent medicines, are in the same category. Indeed, an overdose of any active medicine—of one, for instance, containing antimony, mercury, arsenic, elaterium, digitalis, lobelia—is, naturally, likely to be followed by dangerous results, which may also supervene from mistaking a liniment or a lotion for a medicament intended for internal administration. But for all these there is one simple rule. Wherever a poisonous quantity is sold, caution should be exercised, a proper label affixed, and a record of the sale made. Until this simple rule is put in force, we shall continue to hear of constant accidental and intentional poisonings. A chemist, moreover, and not a grocer or the keeper of an oil shop, is the proper person to dispense poisonous articles of commerce. And whoever buys poisons, it should be made penal not to keep them out of reach. Traps, moreover, are the best things for rats, which do not then go and die in their holes, leaving a stench which may last for months."

The Pharmaceutical Journal.

SATURDAY, JANUARY 12, 1884.

Communications for the Editorial department of the Journal, books for review, etc., should be addressed to the EDITOR, 17, *Bloomsbury Square.*

Instructions from Members and Associates respecting the transmission of the Journal should be sent to MR. ELIAS BREMRIDGE, *Secretary*, 17, *Bloomsbury Square, W.C.*

Advertisements, and payments for Copies of the Journal, MESSRS. CHURCHILL, *New Burlington Street, London, W. Envelopes indorsed "Pharm. Journ."*

REGISTRATION OF TRADE MARKS.

ABOUT six months since, whilst the "Patents, Designs and Trades Marks Bill" was still before Parliament, we gave a brief sketch of its principal provisions, and especially of the part relating to the registration of trade marks. The Bill, which soon afterwards passed, came into operation on Tuesday week last, supplemented by certain regulations as to qualification, forms, fees, etc., for the drawing up of which by the Board of Trade provision had been made. We think, therefore, the occasion a convenient one for laying before our readers, who, many of them, are, or may become, interested in the subject of trade marks, a brief outline of the new law and rules upon the subject, describing the steps necessary to be taken under ordinary circumstances to effect registration of a trade mark. In doing so we shall have to repeat to some extent what was said whilst most of the provisions of the Act were still under legislative consideration, but this will be indispensable to a lucid description. There are some special provisions as to the registration of trade marks in use before the 13th of August, 1875, but we shall confine our remarks to those relating to the registration of new marks.

According to the new Act, the "Patent Office," which term is inclusive of the offices for both the granting of patents and the registration of trade marks, is to be under the immediate control of an officer called the "Comptroller-General of Patents, Designs and Trade Marks," acting under the superintendence and directions of the Board of Trade. It is to this officer that applications for the registration of trade marks have to be made, either directly or through an agent, by persons claiming them. Each application has to be made on a prescribed form,—not, however, that printed in the Schedule to the Act, but one substituted for it by the Rules,—which must be left at, or sent by post to, the Patent Office, accompanied in the case of marks relating to cotton, linen, jute and silk goods by four and in all other cases by three representations of the mark, one on the form of application itself and the others on separate half sheets of paper. It may be here convenient to state that, subject to other instructions from the Comptroller, all applications, notices, etc., have to be on durable foolscap paper, 13 inches by 8 inches, with a margin on the left hand side of not less than an inch and a half, and that all the authorized forms are now included in the Rules, which are purchasable at the Patent Office for sixpence. In virtue of powers conferred by the Act the Board of Trade has divided goods, for the purpose of registration, into classes, which are practically the same as those adopted under the Act of 1875. A trade mark must be registered for particular goods or classes of goods, and only goods contained in one and the same class should be set out in the same application, a separate application being required for each separate class. The fee payable on each application to register a trade mark for one or more articles included in one class is five shillings. The receipt of an application is to be acknowledged by the Comptroller, who may, however, if he thinks fit, refuse to accede to the request to register, the refusal being subject to an appeal to the Board of Trade, which may hear the case and give a decision or refer it to the Court to be tried. As the Comptroller is prohibited from registering as a trade mark any design that is not sufficiently distinct to prevent it being mistaken for any other already registered, it will be seen that unless care is taken to comply with this condition, refusal to register is likely to follow, and this preliminary stage may become both tedious and costly. Before exercising any discretionary power adversely to the applicant the Comptroller must, however, give him ten days' notice of a time when he may be heard personally or by his agent in support of his application. But if no objection be raised, the application is to be advertised, as soon as may be after its receipt, in the official journal, during such times and in such manner as the Comptroller may direct. The advertisement must contain either a representation of the mark desired to be registered or else a reference to a place where one may be seen, and for this purpose the applicant may be required to furnish one or more wood blocks or electrotypes, to the satisfaction of the Comptroller, an extra charge being made if the illustration occupies in the journal a depth of more than two inches. Any person wishing to oppose an application must within two months of the first advertisement give notice of opposition to the Comptroller, in duplicate, stating the grounds upon which it is based, the fee for entering such a notice being twenty shillings for each mark to which it applies. One of the copies is to be sent by the Comptroller to the applicant, who is allowed two months to prepare a counter claim. In the event of this being done the opposition cannot be carried further unless security is given by the person raising it for costs in the trial that would follow. In the event of no opposition being raised, as soon as may be after the expiration of the two months, and on the payment of a fee, which for one or more articles included in one class amounts to twenty shillings, the Comptroller is to effect the registration in the Register of Trade Marks and notify the applicant that this has been done.

For the purposes of the Act a trade mark must consist of or contain at least one of the following essential particulars: (*a*) a name of an individual or firm printed, impressed, or woven in some particular and distinctive manner; or (*b*) a written signature or copy of a written signature of the individual or firm applying for registration thereof as a trade mark; or (*c*) a distinctive device, mark, brand, heading, label, ticket, or fancy word or words not in common use. The Comptroller is not, however, prohibited from entering in the Register, as an addition to the trade mark, any distinctive device, mark, brand, heading, label, ticket, letter, word or figure, or combination of letters, words or figures, though the same is common to the trade in the goods with respect to which the application is made, provided that the applicant disclaims in his application any right to the exclusive use of it. The number of classes into which goods are divided is fifty, of which those most likely to interest our readers are the following:—(1) Chemical substances used in manufactures, photography, or research, and anti-corrosives; (2) chemical substances used for agricultural, horticultural, veterinary and sanitary purposes; (3) chemical substances prepared for use in medicine and pharmacy; (4) raw or partly prepared vegetable, animal and mineral substances used in manufactures, not included in other classes; (8) philosophical and scientific instruments and apparatus; (11) instruments, apparatus and contrivances, not medicated, for surgical or curative purposes; (20) explosive substances; (42) substances used as food or as ingredients in food; (43) fermented liquors and spirits; (44) mineral and aerated waters; (47) candles, soap, detergents, illuminating, heating and lubricating oils, matches, and preparations for laundry purposes; and (48) perfumery. Although a trade mark must be registered for particular goods or classes of goods, several trade marks, resembling each other in the material particulars and differing only in details, may be registered as a series in one registration, each being deemed and treated as registered separately, except that the series can only be assigned as a whole. In this case the fee for registering is to be twenty shillings for the first representation in each class and five shillings for every additional one after the first in each class. A trade mark may be registered in any colour, and this (subject to the provisions of the Act) confers on the registered owner the exclusive right to use the same in that or any other colour.

The registration of a trade mark is to be deemed equivalent to the public use of the mark, whilst the registration of a person as a proprietor of a trade mark will be *primâ facie* evidence of his right to the exclusive use of it, and becomes conclusive evidence at the end of five years. Hereafter no person is to be entitled to institute proceedings in respect to infringement of any trade mark that is capable of registration, unless it has been registered or has been objected to by the Comptroller. A registered trade mark can be assigned and transferred only in connection with the goodwill of the business concerned in the particular goods or classes of goods for which it has been registered and it is determinable with that goodwill. Upon the passing of the right in a registered trade mark from one person to another the new proprietor may upon application to the Comptroller, and, in addition, making a statutory declaration, supplying any other evidence required, and paying a fee of twenty shillings, have his name entered in the Register as such, and the person entered as proprietor is to be deemed for the time being, unless otherwise shown, the person entitled to use and deal with the trade mark. The Register of Trade Marks is to be open to the inspection of the public daily, except on Sundays and holidays, the fee payable being one shilling for every quarter of an hour occupied in the inspection. At a time between two and three months before the expiration of each period of fourteen years from the date of the registration of a trade mark, the Comptroller is to send notice to the then registered proprietor that unless before the expiration of the fourteen years a fee of twenty shillings is paid the trade mark is liable to removal. If the fee be not paid at the expiration of a month a second notice is to be sent, and if the period of fourteen years run out whilst it is still unpaid the Comptroller is authorized to remove the mark from the Register after the lapse of another three months, unless meanwhile he receives the increased fee of thirty shillings. After erasing a trade mark from the Register for this cause the Comptroller is at liberty to restore it upon payment of a fee of forty shillings; but in any case the mark is to be deemed, in respect to any application for registration during the five years next after the date of its removal, a trade mark which is already registered. Besides the foregoing provisions there are others as to corrections and alterations, as well as the settlement of disputes, and the second schedule to the "Rules" contains a series of forms adapted for such emergencies as can at present be foreseen.

It is not surprising that the fatal case of poisoning by a proprietary preparation containing antimony, which was reported in the *Pharmaceutical Journal* last week, has provoked in the public press some outspoken condemnation of the present state of the law in respect to the unrestricted supply of poisons to the public under this and similar forms. It is to be regretted, however, that such condemnations are so spasmodic, and are, as a rule, only uttered under the stimulus of more than usual publicity being given to some particular case out of the many in which, no doubt, injurious results follow the indiscriminate and unintelligent manner in which preparations containing powerful poisons are now scattered broadcast among the community under cover of the patent medicine stamp. One most disheartening feature is the marked absence, where it might fairly be expected, of the knowledge of existing facts, so essential to any useful discussion of the subject, as, for instance, it is manifested by an important public officer when, whilst acting in a semi-judicial character, he talks about persons being able to "take out patents without being compelled to state the ingredients," or when the editor of a leading daily paper, under a similar misconception as to what constitutes a "patent medicine," expresses a "regret that the Patents Act, which has just come into operation, contains no provision dealing with this matter." In like manner, a medical gentleman, in a letter printed on another page, writes as if pharmacists had not yet given any consideration to the subject, and expresses astonishment at a fact in respect to the persons who carry on the patent medicine manufacture, with which everyone connected with medicine or pharmacy might be expected to be familiar.

* * *

An Evening Meeting of the North British Branch of the Pharmaceutical Society will be held on Wednesday next, in the Rooms, 119A, George Street, Edinburgh, when papers will be read on "Salts of Nicotine," by Mr. D. B. Dott; "Preparations of Galazyne, or Artificial Koumiss," by Mr. A. Gibson; and "Aqueous Mixtures containing Chlorate of Potash," by Mr. J. R. Hill.

* * *

Wednesday next is the date fixed for the Chemists' Eighteenth Annual Ball, and it would hardly be necessary to call attention here to the fact were it not that the reminder may save some of our readers disappointment through neglecting until too late to secure the tickets they require, as the number is to be strictly limited. Applications should be made at once to the Honorary Secretary, Mr. F. W. Warrick, Old Swan Lane, E.C., or to one of the other gentlemen whose names are mentioned in the advertisment.

* * *

Another social gathering of pharmacists and their friends that seems to increase in favour with every repetition is the Annual Soirée of the Midland Counties Chemists' Association, which is to be held this year as usual in the Town Hall, Birmingham, on Friday, the 25th inst. Tickets may be had from the Stewards or Mr. C. Thompson, Honorary Secretary, Stratford Road, Sparbrook.

* * *

We learn from an advertisement that the Madras Government has decided to adopt the advice given by Dr. Trimen and appoint a chemist as quinologist in connection with the Nilgiri Cinchona Plantations. The appointment is to be for five years, and the desiderata for it are a thorough qualification in the practice of organic analysis, and, if possible, experience in the analysis of cinchona bark, whilst the salary offered is 350 rupees per month, rising to 500 rupees, with a free passage to India and back. The estimate of the Government as to the value of the services that can be rendered by the new officer, so far as it is revealed by the remuneration, appears to be somewhat moderate, and considering the rarity of the most essential qualification, a practical experience in bark analysis, it is in our opinion considerably below the requirements of the case.

* * *

A report has just been issued dealing with the Oxford Local Examinations held at thirty-six centres in June last. From this it appears that the total number of candidates examined was 1845 (1192 juniors and 653 seniors), of whom 1055 (636 juniors and 419 seniors), or 57 per cent., passed; some of the 160 seniors were unsuccessful in more than one of the essential "preliminary" subjects, as there were 81 failures in grammar, etc., and 127 in arithmetic; but taking those who only failed in one "preliminary" subject, there were 34 unsuccessful in grammar, etc., and 79 in arithmetic. In like manner among the 277 unsuccessful junior candidates there were two failures in reading, three in writing, nine in spelling, 75 in dictation, 81 in grammar, and 174 in arithmetic; but of those who failed in one "preliminary" subject only 34 were incompetent in dictation, 34 in grammar, and 138 in arithmetic. The number of failures in arithmetic is very suggestive of imperfect teaching of this essential branch of education, but it is quite in accordance with the experience in connection with the Preliminary examination of the Pharmaceutical Society.

* * *

According to a statistical abstract of failures in the United Kingdom, published in *Kemp's Mercantile Gazette*, the total number of persons who failed in business in the course of the year 1883 was 11,465, of whom 93 were described as chemists and druggists, against 87 in the previous year. The bills of sale registered, however, during the same time, fell in the case of chemists and druggists from 223 to 79.

* * *

On Thursday evening, January 3, Dr. MacAlister delivered at the London Institution a lecture, the title of which was "How a Bone is Made." He commenced by showing the construction of the femur, and then opened an interesting discussion upon the advantage of the shape and hollowness of that bone. He spoke of the femur as consisting of a hollow tube, broadening out into lobes at either end, which were filled with a cancellated mass. In comparing the value of several materials as to their capabilities of sustaining tension or compression, the lecturer mentioned that in both steel and bone they were found to be nearly equal, whilst cast iron could withstand nearly six times as much power used in compression as that used in tension. In the use of cast iron, therefore, a great deal of material would be wasted in the making of the tension power up to the required capability, and this would necessitate bulkiness in comparison to bone and steel. With reference to the hollowness of the bone, Dr. MacAlister explained very clearly that the strength of the bone did not nearly decrease in the same ratio as the quantity of of material taken from the interior. As an example of this he showed that although a femur of a person of twenty-one years of age weighed nearly two and a half times as much as a femur of the same external appearance and size, which had belonged to a person of one hundred and three years of age, and had become more hollow with age, nevertheless the latter was very nearly as strong as the former.

* * *

At the next meeting of the Chemical Society, to be held on Thursday, January 17, papers will be read on "Camphoric Peroxide and Camphorate of Barium," by C. T. Kingzett; "On the Decomposition of Silver Fulminate by Hydrochloric Acid," and a "Supplementary Note on Liebig's Production of Fulminating Silver without the use of Nitric Acid," by Messrs. Divers and Kawakita, and "On Hyponitrites," by Messrs. Divers and Haga.

Transactions of the Pharmaceutical Society.

MEETING OF THE COUNCIL.

Wednesday, January 9, 1884.

Present—

MR. MICHAEL CARTEIGHE, PRESIDENT.

MR. SAMUEL RALPH ATKINS, VICE-PRESIDENT.

Messrs. Borland, Bottle, Butt, Churchill, Gostling, Greenish, Hampson, Hills, Radley, Richardson, Robbins, Savage, Schacht, Symes, Williams, Woolley and Young.

The minutes of the previous meeting were read and confirmed.

The VICE-PRESIDENT said he had been glad to see published in some of the daily papers the list of the examiners. He should also like to see the result of the examinations published in the same way. He understood this was done in Scotland.

The PRESIDENT said there would be no objection to this if the names of unsuccessful candidates were not given. The information could be sent to the press, but of course its insertion could not be guaranteed.

THE LATE MR. J. E. HOWARD, F.R.S.

The PRESIDENT read a letter received from Mrs. Howard, in acknowledgment of the letter of condolence sent her, and also thanking those members of the Council and other officers of the Society who had attended the funeral.

THE BOARD OF EXAMINERS.

The Secretary read a letter, which had been received from the Privy Council, approving the appointment of the Examiners appointed last month.

DIPLOMAS.

The following, being duly registered as Pharmaceutical Chemists, were respectively granted a diploma stamped with the seal of the Society:—

Bing, Charles.
Burford, Samuel Francis.
Collins, Herbert Sleight.
Cornwell, Thomas Chinsura.
Dolbear, John.
Dymond, Thomas Southall.
Jones, Charles.
Low, David.
Mitten, Flora.
Mowatt, John Rodman.
Sergent, William Thomas.
Taylor, Ernest Sanderson.

ELECTIONS.

MEMBERS.

Pharmaceutical Chemists.

The following pharmaceutical chemists, having passed the Major examination and tendered their subscriptions for the current year, were elected "Members" of the Society:—

Bing, Charles	Canterbury.
Burford, Samuel Francis	Leicester.
Collins, Herbert Sleight	Bradford.
Cornwell, Thomas Chinsura	Penzance.
Loumeau, Edmond	Mauritius.
Low, David	Hexham.
Mitten, Flora	Hurstpierpoint.
Mowatt, John Rodman	London.
Phillips, John Edwards	Ealing.
Pirie, William	Edinburgh.
Sergent, William Thomas	North Shields.
Taylor, Ernest Sanderson	Grantham.

Chemists and Druggists.

The following chemists and druggists, who were in business on their own account before August 1, 1868, having tendered their subscriptions for the current year, were elected "Members" of the Society:—

Coley, James	Bootle.
Evans, William	Mold.
McMurray, James	Helensburgh.
Nicholson, William Ostler	London.
Shepherd, Charles William	Ilkley.
Sleight, William Wilson	New Wortley.
Trundle, William E. Rust	Plaistow.

ASSOCIATES IN BUSINESS.

The following, having passed the Minor examination, being in business on their own account, and having tendered their subscriptions for the current year, were elected "Associates in Business" of the Society.

Brook, Samuel Verlander	Cradley.
Grove, Harry Nicholas	Walsall.
Jones, John Wesley	Llanelly.
Laing, Arthur Laurenson	Lauder.
Law, Thomas Wm. Thorburn	Partick.
Robertson, Alexander	Oban.

ASSOCIATES.

The following, having passed their respective examinations and tendered their subscriptions for the current year, were elected "Associates" of the Society:—

Minor.

Ashton, Charles Sampson	Yeovil.
Barnes, William Robert	Plaistow.
Bell, Charles Russel	London.
Brampton, Wm. Saml. Howes	Stanion.
Brown, Edgar Marshall	Derby.
Brown, Horace	Thrapston.
Daniel, George	Holsworthy.
Farrer, Edward	Kendal.
Gibson, John	Barnard Castle.
Jackson, Walter	Catterick.
Jackson, William John T.	Lytham.
Lipp, George	Elgin.
Morris, Henry Ridley	Ipswich.
Owen, Henry	Gravesend.
Rees, David	Haverfordwest.
Richardson, John	Mansfield.
Riley, John Cowgill	York.
Roberts, Rowland	Holyhead.
Robertson, Charles	Edinburgh.
Shacklock, James Harvey	South Cave.
Smith, Albert Edward	Sudbury.
Stocker, George	Exeter.
Sutherland, Adam Gordon	Edinburgh.
Tallantyre, John Mortimer	Manchester.
Wride, Francis Blake	Shirley.

Modified.

Price, Benjamin William	Farnham.

APPRENTICES OR STUDENTS.

The following, having passed the Preliminary examination and tendered their subscriptions for the current year, were elected "Apprentices or Students" of the Society:—

Allen, Richard	Ramsey.
Anthony, Thomas	St. Austell.
Aston, Alfred Valentine	Tarporley.
Balmford, John Archibald	Huddersfield.
Bard, Cecil Harry	Exeter.
Barritt, Ernest Henry	Colchester.
Barton, John	Warwick.
Bates, John	Bicester.
Bates, John	Manchester.
Baxter, George Munnerley	Chester.
Black, James Watson	Aberdeen.

Bonnett, Frederick	Doncaster.
Boole, Lucy Everst	London.
Bostock, John William	Ashton-under-Lyne.
Brown, Henry Armstrong	Sunderland.
Browne, John	Lowestoft.
Casewell, Job Parry	Market Drayton.
Chamberlain, Charles John	Portsea.
Courtis, Terrell	London.
Cullinan, Edward, jun.	London.
Dancy, Ralph	Turner's Hill.
Dell, Frederic Barton	Llanelly.
Donack, James	Moffat.
Dunn, Isaac George	Chard.
Earle, Ernest Haworth	Hull.
Egg, George Frederick	Highbury.
Evans, Daniel Thomas	Llandyssul.
Farlow, James Southward	London.
Featherstone, Robert Horne	Derby.
Fellows, Vincent Litchfield	Hampstead.
Fifield, Tom Hadley	Birmingham.
Fletcher, Harold Goodwin	Ripley.
Fothergill, Alfred	Newport (Mon.)
Fuller, George Sydney	Thornton Heath.
Golds, Lewis George	Steyning.
Golightly, John William	Durham.
Griffiths, Cornelius Albert	Cinderford.
Hampson, Herbert Edwin	York.
Harrison, Thomas	Birmingham.
Hearnden, Frederick	London.
Henderson, Thomas Cuthbert	Lochee.
Hepworth, John Stafford	Hyde.
Herbert, Henry William	Barton-on-Humber.
Hider, Francis	London.
Hind, William Tom	Leicester.
Hobbs, Alfred Ernest	Tunbridge Wells.
Horne, Joseph	Aberdeen.
Hughes, Philip Henry A.	Liverpool.
Johnston, William	Montrose.
Johnstone, John	Selkirk.
Jones, Edwin Pryce	Aberdare.
Kent, Charles Edwin	Hertford.
King, James, jun.	Kilmalcolm.
Lewis, John Lloyd	Llandyssul.
Lockyer, Cuthbert Henry Jones	Bruton.
Manfield, Robert Hall	Pontefract.
Matthews, Edwin James	Cowbridge.
Maudson, Charles Fredk.	Leeds.
Meacham, Vincent Whittenbury	Ledbury.
Mitchell, John	Inverness.
Munro, James Innes	Perth.
Padley, Frank Robert	Birmingham.
Paine, William	Ashton-under-Lyne.
Parry, John	London.
Paternoster, George Sidney	Cirencester.
Patterson, David	Bolton.
Potts, Robert	Newcastle-on-Tyne.
Price, Peter	Bromsgrove.
Purchase, Francis William	Bideford.
Rees, John	Aberystwith.
Roberts, Willam Arthur]	Bangor.
Sales, John William	Doncaster.
Salter, Albert Joseph	Uckfield.
Scott, Walter H.	Beverley.
Selby, Henry Collingwood	London.
Smith, Edward Gibbs	Walton-on-the-Naze.
Smith, Samuel Henry	Leamington.
Stuart, Findlay	Dumbarton.
Sursham, Frederick Thomas	London.
Townsend, William Thomas	Bradford.
Tugwell, Ernest Harry	Greenwich.
Turner, Ebenezer	Whifflet.
Twivey, Arthur	Tadcaster.
Webster, John, jun.	Buckie.
Whitehead, John Henry	Leeds.
Williams, Alfred	London.
Williams, Joshua Edward	Bryn Glas.

Restoration to the Register.

The name of the following person, who had made the required declarations and paid a fine of one guinea, was restored to the Register of Chemists and Druggists:—

Sutton Dudley Gill, 221, Spon Lane, West Bromwich.

Several persons were restored to their former status in the Society upon payment of the current year's subscription and a fine.

Additions to the Register.

The Registrar reported that—

William Botterill Parker, 5, West Street, Leeds, and
Henry Barker Travis, 528, Brightside Lane, Sheffield,

having respectively made statutory declarations that they were in business before the passing of the Pharmacy Act, 1868, and these declarations having been supported by duly qualified medical practitioners, their names had been placed on the Register.

Reports of Committees.

FINANCE.

The report of this Committee was received and adopted, and sundry accounts were ordered to be paid.

Mr. Greenish suggested that it would be well if in each case the resolution approving the reports of committees should be moved by the member who had acted as chairman of the committee. He could then draw the attention of the Council to any subject which seemed to require notice.

Mr. Richardson supported the suggestion. He said it was very important that the attention of the Council should be called to anything in connection with these reports which was of general interest.

Mr. Schacht suggested that it would be a great convenience in the conduct of business if a permanent chairman were appointed to the Finance Committee each year. The business of this Committee differed from most others in being of a character not so readily mastered, and he had often noticed that information had to be obtained from the Secretary or the office on the bearing of certain matters which came before the Committee.

Mr. Williams said the bye-laws provided that the President or Vice-President should preside at the meeting of any Committee at which they were present.

Mr. Schacht said it would be very easy for the President or Vice-President to be appointed chairman of the Finance Committee for the year.

Mr. Gostling said it had been the practice for the Vice-President to act as chairman of the Committee, and if he was not present there was generally a former President or Vice-President who could fill the post.

The Vice-President thought it would be very well to have a permanent chairman for the Finance Committee.

Mr. Richardson said it was impossible for the President or Vice-President to take the chair at every meeting of a committee, but it would be very useful to have a permanent chairman of the Finance Committee.

Mr. Young thought it was a pity to disturb the existing arrangements which had worked so well, and it seemed very proper that the President or Vice-President should preside at the Committee meetings. The point raised by Mr. Greenish was simply that whoever had officiated as chairman of the Committee should bring forward the report and mention any point which required notice.

Mr. Greenish remarked that he was quite satisfied, after what had been said, to leave the matter in the hands of the President.

BENEVOLENT FUND.

The report of this Committee included a recommendation of the following grants:—

£20 to a former member, aged 62, who had a similar grant in 1880. Suffering from a paralytic seizure. Surrey.

£10 to the widow of a registered chemist and druggist, aged 49; has six children. Applicant has had two previous grants. Middlesex.

£10 to the widow of registered chemist and druggist, aged 42. In ill health; has three children. Has had three grants previously. Lancashire.

£10 to a registered chemist and druggist, aged 40. Formerly in business, but now out of employment. Middlesex.

£20 to a former member and subscriber to the Benevolent Fund, aged 62. Applicant has had three previous grants and was an unsuccessful candidate at the last election. Middlesex.

£10 to the widow of a registered chemist and druggist, aged 63. Has had three previous grants and was an unsuccessful candidate at the last election. Surrey.

£21 to be placed in the Secretary's hands and used at his discretion in securing the election of the youngest of Ord's orphans to the London Orphan Asylum.

The Committee recommended the addition of certain names and amounts to the Benevolent Fund Donation Board and the alteration of the amounts in other cases where the donations had been increased.

The Committee had considered the regulations for the distribution of the Fund and recommended the following alterations*:—

Rule 8. "In all petitions for assistance from the Fund the truth of the statements shall be certified by at least two Members or Associates in Business of the Society, or two donors or subscribers to the Fund, who are personally acquainted with the facts of the case."

Rule 9 to be concelled.

The Vice-President, in moving the adoption of the report, said he was glad to see that the attention called to the Benevolent Fund was finding a response outside. The question raised by Mr. Hampson's letter, calling attention to the difficulty which might arise in initiating applications for relief, had been reconsidered and after full and careful consideration, the decision arrived at was that two signatures only should be required, either of members, associates or subscribers, but that no limit of amount should be placed on the subscription qualifying the signature to be appended. If there had been any difficulty in getting recommendations, that would now be obviated, and he trusted this conclusion would be accepted.

The President said the change practically consisted in reducing the number of signatories from four to two, and abolishing the restriction as to the length of time during which the subscription had been current and the amount.

Mr. Schacht seconded the motion.

Mr. Bottle moved as an amendment—

"That the recommendation of the Benevolent Fund Committee to reduce the number of signatures from four to two on the application paper for relief be not entertained, but that the number of signatures be four as heretofore."

* The following are the clauses in the Regulations proposed to be amended:—

"8. In all petitions for assistance from the Fund the truth of the statements therein contained shall be certified by at least four members of the Society, or donors to the Fund of five guineas, or persons who have subscribed not less than half-a-guinea per year for the three preceding years, and who are personally acquainted with the facts of the case.

"9. In the case of a widow or orphan applying for relief and unable to obtain the required evidence under Rule 8, the Council will receive and consider in lieu of such evidence the testimony of four respectable householders, to whom the circumstances of the applicant are known, provided that the persons so certifying are respectively subscribers or donors to the Fund of not less than half-a-guinea for the current year."

He thought there had been no necessity shown for the alteration, and he was conservative enough to believe in keeping things where they were when no cause was shown for change. The Council was told that difficulties might arise, but he thought the regulations might remain *in statu quo* until difficulties did arise. He also spoke in the interests of the applicants, because the Committee scrutinized every recommendation which came before it, and if one came signed by two names only and another signed by four, he thought the applicant recommended by four, would have a considerable advantage over the other. The decision was only come to in committee by a narrow majority, and therefore he thought it might be reviewed. It might be said there was a difficulty in a deserving candidate getting signatures, but he did not think that there was, and inasmuch as it necessitated the petition being handed about before it was presented to the Council, it was an advantage to the Fund. He was quite willing to allow a subscriber of any amount the privilege of nominating, but did not like to see the number of signatories reduced.

Mr. Robbins seconded the amendment, as he thought the proposed alteration would prove pernicious. He had had some experience of the Benevolent Fund and had never found this difficulty arise. The Committee was generally guided by the fact that the application was supported by persons of whom something was known, and although four names were necessary in the majority of cases one good name was sufficient to act upon. Now the Committee might not be able to pick one good name out of two so well as one out of four, and considering the other alterations, the names would not be so good. A paper might be signed by two apprentices, and if made too easy some might be tempted to apply to the Fund who otherwise would not have done so. When it required the names of influential members of the Society there was some difficulty, no doubt, and there was an advantage in there being some little difficulty in obtaining relief, but these difficulties had not been sufficient to prevent applicants coming forward, seeing that in the last year nearly £2000 had been expended. If it were necessary to make any change at all, let the Council insist on the signature of the Local Secretary, or someone it knew something about.

Mr. Hampson was sorry that this question did not seem likely to be settled without another discussion. When the report of the Committee was read he felt grateful to the Committee for arriving at a conclusion which, if carried out, he felt sure would not only promote the interests of the Fund, but make the investigations as to the character and position of the applicants more easy, and probably the information when obtained would be of a better quality. He could not understand the objection of the last speaker, that if only two persons signed the paper their names would be of little use. He also said that one signature generally guided the Committee, and surely out of two there might be one in whom the Committee would have confidence. He maintained that it was a hardship that a person who signed these papers should have either to be a donor of five guineas or a subscriber of half-a-guinea for three years, and in many cases applicants had to undergo great trouble and inconvenience in getting signatures.

The President reminded Mr. Hampson that the only point in question was whether the number of names should be two or four.

Mr. Hampson thought the proposal of the Committee would in no way damage the Fund. He could not agree that there had been no inconvenience in the past; there had been great inconvenience in getting the right signatures, and almost invariably the names attached to the papers had not the quality mentioned by the Treasurer, that is to say persons signed the paper not of their own personal knowledge.

Mr. Robbins explained that his meaning was, if there were four signatures there was a greater probability of finding one amongst them whom the Committee knew than if there were only two. As to the quality of the signatures he thought there was a better quality now than there would be under the proposed alteration, which might mean only the signatures of two apprentices.

Mr. BORLAND said the members of the Council seemed to be all agreed as to the abolition of the restriction on the amount, and the only difficulty was as to the number. Now on looking over the Calendar he found that out of about six hundred and eighty places or towns in which there were chemists subscribing to the Fund there were only one hundred and thirty-seven in which there were four subscribing chemists, the remaining five hundred and forty not having the necessary number. If then the number were maintained at the four the applicants at those places must go outside their own district to find two additional subscribers. In Kilmarnock any person requiring four signatures would have to go at least twenty miles, and then would only get individuals who in all probability knew nothing whatever of the character of the applicant. On that ground he supported the report of the Committee.

Mr. SAVAGE thought the suggestion of the Committee a very wise one, and scarcely thought the mover of the amendment was right in stating that hitherto the regulations had worked well. The Council was really not in a position to know what difficulties had arisen in obtaining signatures, and no doubt there had been considerable difficulty here and there which the Committee knew nothing about. If the minimum number was reduced to two, it did not prevent the Committee obtaining further information if necessary.

Mr. WOOLLEY supported the amendment. He had been for some years on the Benevolent Fund Committee, and no difficulties had come under his notice, and it was not usual to legislate for difficulties of which one had no knowledge. He thought the Council should be content with a reduction of the amount, which would increase the number of subscribers; and to meet the point suggested by Mr. Borland he thought there would not be much difficulty in getting two persons in a place to subscribe a small amount, and thus become eligible to sign the paper.

Mr. HILLS suggested that the decision on this point should be deferred; it was rather difficult for those not members of the Committee to vote suddenly on a question of this kind, altering the regulations which had been in force for many years. He had not yet heard of any case of difficulty which had arisen, and should be inclined to leave things as they were, but perhaps if he had further time to consider the alterations he should be better able to form a judgment. He asked if he correctly understood the proposition, that two apprentices by each giving a donation of half-a-crown for a specific object should be able to sign an application paper.

The PRESIDENT said, Certainly.

Mr. HILLS said he objected to that altogether.

Mr. HAMPSON said the Council did not contemplate such a case arising. If thought desirable it might be limited to householders or persons over twenty-one years of age.

Mr. RICHARDSON said some gentlemen seemed to lose sight of the fact that the object of the Benevolent Fund Committee was to get in all possible applications with the least possible difficulty to the applicant. It did not at all follow that all applications would be acceded to. The Committee sat every month to sift these applications, and even if two apprentices signed an application for relief, it did not follow that the Committee would act on the suggestion. Each case was first sifted by the office, and then submitted to the Committee, so that there was every possible safeguard. He hoped this discussion would have the effect of increasing the number of chemists and druggists who subscribed to the Fund. No doubt the previous arrangements were somewhat restrictive, and in small towns it must be difficult for persons to get their applications signed. At the present time it was often found that the signatories were members of wholesale houses in some other town. Only on the previous evening there had been a case in which the application was signed by three or four wholesale druggists, who could not possibly have that knowledge which even an apprentice might have in the town from which it emanated.

Mr. SYMES said although difficulties had not been numerous no doubt some had arisen which had not come under notice, and as the matter had been under consideration for a month it would be as well to come to a decision. The members of Council seemed all agreed that the existing rule was a hardship, but he should support Mr. Bottle's amendment if he meant to limit the number to two subscribers; in fact, that there should be four names, including two subscribers, whose names should appear on the Register of Chemists and Druggists, and two respectable householders. He could not conceive any place where a difficulty may arise in a person getting such signatures. There was a little danger in making it too easy to obtain relief; it had a prejudicial influence on the candidates themselves, for it was a remarkable fact that when a person found out the means of getting a grant he generally came again. Under the new regulation the paper might be signed by persons not subscribers.

Mr. WILLIAMS said he strongly supported in committee the view taken by Mr. Bottle that the number of signatories should be four. He did not consider that number at all too many, and even if it were increased it might be a safeguard to the Committee. It was very important that the Committee should not be misled in any way by misstatements or informal applications; there was a greater safety in four signatories than in two, but he did not at all agree with Mr. Symes that those who did not subscribe at all should have the privilege of signing the paper. He was quite willing and anxious that the alteration should be made so far as taking away the restriction that persons must have subscribed half-a-guinea a year for three years previously, which, no doubt, was a hardship; but he thought the amount of half-a-guinea ought still to be retained, as the lowest amount to be subscribed by those who signed the paper, though he was willing to waive that, and accept the half-a-crown, which was the smallest amount taken, if the Council thought fit. He had hoped, however, that the Council would reverse the decision carried by a very small majority in the Committee, and insist on four names being appended.

Mr YOUNG said it seemed to be generally accepted that the present arrangements were not satisfactory, owing to the difficulties which applicants might have in finding four individuals in a small place who were subscribers of half-a-guinea to the Fund. The question seemed to be whether the subscribers to the document should be two or four, but since he had been a member of the Committee he had often noticed that, while there were four subscribers' names attached, when these persons were written to they often replied that they knew very little about the applicant. That arose from the circumstance mentioned by Mr. Richardson that in many cases they were members of wholesale houses with whom the applicant had done business. The Committee would not be tied to two, but might still require four; in addition to that the Council knew the careful investigation which was made in every case by the Secretary; he, therefore, thought it would be a great improvement if the nnmber was limited. He certainly was not prepared for the statement that two apprentices might sign the document, and he should certainly prefer two householders; two good names would be better than a long list of persons who did not know the applicant personally.

Mr. GREENISH said he should support the amendment. Two questions were considered in the Committee, one whether this clause, with regard to the subscribers of half-a-guinea for three years, should be retained, and the other, whether four names were necessary, or whether the number should be reduced to two. He was quite agreed with the first alteration, that any subscriber to the Fund should be eligible to sign; but, having made that concession, it was more than ever important that there should be four names, because they were now likely to include a different class of subscribers. A person might get two apprentices to sign their names, but it was not likely he would get four.

Mr. Radley supported the proposition of the Committee, and he was influenced in this course, to a certain extent, by the difficulty that had been experienced with regard to widows. There was frequently great difficulty in widows getting their papers properly signed, they not, as a rule, being known to members of the trade. He certainly felt a little objection to the idea of the paper being signed only by two apprentices, and should prefer the word "householders;" but the process was only the initiatory one.

The President said the lines on which some members of the Council seemed to regard the application paper were, in his opinion, quite erroneous. They seemed to look upon this paper as a passport to the money; but it was nothing of the sort. It was intended so to be when first instituted, but it had proved utterly untrustworthy. He asserted that as the result of his experience during the last two and a half years and from former experiences on the Benevolent Fund Committee. When there were four signatures, it might be of large subscribers or respectable members of the Pharmaceutical Society, the chances were that the case was not known to more than one out of the four persons signing, and the intention that the application paper should be a passport to a grant was a failure. That being so he preferred to regard the paper as a simple recommendation that the case should be considered. If that were so, was it necessary to ask for four signatures? The question had been discussed in committee whether householders alone should be eligible; but the Secretary, who had more to do with the Benevolent Fund than all the Council put together, had during the recess actually proposed that the alteration should be—and he agreed with him—that any householder should sign. The Secretary said the limiting of the signatories in the case of non-members and non-associates to subscribers did not produce money to the Fund, and he (the President) did not think it did. The real information on which a committee made a grant was that obtained on an application for further information to either one or all of the individuals signing, and the Committee often referred to other persons, or applied direct to the Local Secretary. The paper ought to be regarded as no more than it was worth, the preliminary or initial stage. It would have been impossible to give the relief that had been given if each of the four persons who had hitherto signed these papers had been obliged to swear that he was personally acquainted with the cases for the number of years stated, and could confirm all the particulars to the best of his belief. What was really wanted was to get at one or two persons who knew the case, not a number of respectable people who would support, but who did not know it thoroughly. He believed that by reducing the numbers from four to two the chance of getting the right information would be increased, and the temptation to sign the paper formally out of kindness decreased. With regard to apprentices, why should not they sign if they were subscribers and knew the case. Members and associates of the Society were practically subscribers by virtue of the large sums tranferred from the General Fund to the Benevolent Fund in days gone by, and to that extent, therefore, it was considered that every member and associate in business was a subscriber. If the signatories were limited to members, associates or subscribers, why should not apprentices, if subscribers, be eligible? It was not at all likely that many would be unable to get signatures except from two apprentices, but if any person could not it was no reason his case should not be investigated. The Committee did not make a grant on the application, but on the investigation. On these grounds he hoped the Council would take a broad view, and adopt the report.

Mr. Churchill said he was glad this discussion had taken place in order that subscribers might see how carefully the Fund was administered. He quite agreed with the President in believing that the main thing which influenced the Committee was the application of the Secretary to the signatories for an exact account of what their real knowledge of the person was, and further than that he had the opportunity of asking the Local Secretary or a member of the Council to look into the case. In that way the Committee had often been able to get at facts which did not appear on the application paper.

Mr. Williams said it seemed a most extraordinary line of argument that two names should be better than four.

The Vice-President said the amendment would permit four apprentices to sign, but he did not think many apprentices would do so. He wished to emphasize one point, viz., that this was nothing but the initiatory stage; it was the collateral evidence by which the Committee was guided.

The amendment was then put with the following result:—

For—Messrs. Bottle, Butt, Churchill, Greenish, Hills, Robbins, Symes, Williams and Woolley.

Against—Messrs. Atkins, Borland, Carteighe, Gostling, Hampson, Radley, Richardson, Savage, Schacht and Young.

The amendment was, therefore, lost.

Mr. Williams then moved as an amendment to the original motion—

"That after the word 'subscribers' the words 'being householders' be inserted."

He thought it would be very dangerous if papers were to be signed by apprentices or anybody else who might choose to put down half-a-crown for the privilege of signing.

Mr. Hills seconded the amendment.

Mr. Hampson hoped that Mr. Williams would withdraw this amendment as it would exclude all assistants who might be interested in the Fund.

Mr. Williams said if there were a paper signed by two apprentices and the Secretary wrote to them for further information, what guarantee was there that he would get anything like a proper and reasonable statement of the case. When the Council was administering a fund collected all over the country it ought to take the greatest care that the money was distributed properly. If any person wanted a grant he could not have much difficulty in finding two subscribers who were householders.

Mr. Savage said the great point to be remembered was that this was merely the initiative. The Committee was not limited to those two individuals; the Secretary had the opportunity of writing to the Local Secretary, or anyone he knew.

The President hoped the Council would vote upon this amendment without entering into another long discussion. It appeared to him that the testimony of two educated apprentices was quite worthy of attention.

Mr. Woolley said it was not at all a question of the respectability or education of the apprentices, but it was a question of whether a man was of full age or not. There were apprentices perfectly competent to initiate an application of this kind, but there were others who would not be. It seemed to him the Council was making a sudden departure without any reason, and opening the door far too wide for those applications.

Mr. Richardson considered that every person who subscribed to the Benevolent Fund was entitled to sign an application for relief.

Mr. Greenish thought now the subscription was lowered to half-a-crown some method of hedging the Fund round should be adopted.

Mr. Gostling suggested that the word "householders" might lead to difficulties. He should prefer a limit of age.

The amendment was then put with the following result:—

For—Messrs. Bottle, Butt, Churchill, Hills, Radley, Williams and Woolley.

Against—Messrs. Atkins, Carteighe, Gostling, Hampson, Richardson, Savage and Schacht.

Messrs. Borland, Greenish, Robbins, Symes and Young were present at the division, but did not vote.

The numbers being equal the President gave his casting vote against the amendment.

Mr. Bottle then proposed another amendment.

"That the proposed alterations be printed and referred back to the Benevolent Fund Committee to report upon."

Seeing the division was so very close it appeared to him to be the wisest course to adopt.

Mr. Hills seconded the amendment.

Mr. Hampson said he had confidence in the Committee's report. This was the second time it had considered the question, and surely its decision ought to be treated with some respect.

Mr. Gostling supported Mr. Bottle's suggestion. He thought there was nothing to be gained by precipitancy, and as there was such an even balance of opinion on each side, he thought it would be much better to wait until the members of the Council were more at one as to the desirability of the alteration.

Mr. Schacht said he should regret if this question were again deferred. Last month he gave his reasons for the opinion he then expressed in favour of making the thing as open as possible, providing the recommendation was limited to those who in some form or another supported the Fund. He deprecated any further postponement of the question, because at the February meeting there would be a great deal of other business to do.

The Vice-President also hoped that it would not be deferred, as it would lead to a great waste of time in going over the whole question again.

Mr. Robbins said the new Calendar was issued at the beginning of the year; the regulations there given would therefore be wrong for the next twelve months if the proposed alterations were now made.

Mr. Symes said the error would be in the right direction. He did not think anything would be gained by reconsidering the subject.

The President said the Committee was very equally divided before, and would be equally divided again. It would be much better to settle the matter one way or the other.

Mr. Greenish said he was surprised to hear any member of the Council say it was a waste of time to discuss a question of this importance.

Mr. Bottle said he would withdraw the amendment, but in doing so he wished to protest against the assertions made over and over again that the recommendatory paper was only the initiative. It was so in the sense of bringing the matter before the Council, but it was the line upon which the Secretary at once acted in getting the information upon which the Council made the grants. He for one personally knew nothing of any individual who came forward on the previous evening as recommended for relief; he accepted what was placed before him as evidence to judge of their merits, but in each case the Secretary had travelled on the lines of the application paper.

The original motion for the adoption of the report was then put and agreed to.

Robbins' Fund.

Mr. Robbins said he had been requested by the Benevolent Fund Committee to transfer the South Metropolitan Gas Shares to 4 per cent. Debentures of the Gas Light and Coke Company, which he had done. The shares realized £129 12*s.*, and the Debentures were £134 16*s.*, so that there was a difference of £5 4*s.*, which he had made up. He moved that the seal of the Society be affixed to the transfers.

The motion was seconded by the President, and carried.

LIBRARY, MUSEUM, LABORATORY, AND HOUSE.

Library.

The report of the Librarian had been received, including the following particulars:—

Attendance.		Total.	Highest.	Lowest.	Average.
November	Day	478	28	9	18
	Evening	243	19	5	11

Circulation of books.	Town.	Country.	Total.
		No. of Entries.	
November	191	138	329

Carriage paid, £1 17*s.* 11*d.*

The following donations to the Library had been received, and the Committee recommended that the usual letter of thanks be sent to the respective donors:—

Allgemeiner österreichischer Apotheker - Verein, Zeitschrift, 1883. From the Verein.

Alumni Association of the Philadelphia College of Pharmacy, Nineteenth annual report, 1883. From the Association.

American Journal of Pharmacy, 1883. From the Philadelphia College of Pharmacy.

American Pharmaceutical Association, Proceedings, vol. 30. From the Association.

Analyst, 1883. From the Editors.

Annuaire des Spécialités médicales et pharmaceutiques, 1883. From the Publishers.

Archiv for Pharmaci og technisk Chemi, 1883. From the Publishers.

Botanical Society [of Edinburgh], Transactions, vol. 14, part 3. From the Society.

British Pharmaceutical Conference, Year-Book of Pharmacy, and Transactions, 1882. 2 *copies.* From the Conference.

Canadian Pharmaceutical Journal, 1883. From the Ontario College of Pharmacy.

Chemical News, 1883. From the Editor.

Chemical Society of London, Journal, 1883.

— List, 1883. From the Society.

Chemist and Druggist, 1883.

Chemists' and Druggists' Diary, 1884. From the Proprietors.

Chemists and Druggists' Trade Association, Seventh annual report, 1883. From the Association.

Ephemeris of Materia Medica, Pharmacy, Therapeutics, etc., 1883. From Dr. Squibb.

Victoria, Pharmaceutical Register for 1882. From the Pharmacy Board of Victoria.
Wisconsin Pharmaceutical Association, Proceedings, 1883. From the Association.
Yorkshire College, Ninth Annual report, 1883. From the College.
Dragendorff (G.), Plant Analysis, translated by H. G. Greenish, 1883. From the Translator.
Jones (H. M.), Treatise on aural surgery, 2nd ed., 1881.
— Atlas of Diseases of the Membrana Tympani, 1878. From the Author.
Plugge (P. C.), Natriumhypobromit als Reagens zur qualitativen und quantitativen Bestimmung des Ammoniakharzes, 1883. From the Author.

The Committee recommended the purchase of the undermentioned books:—

Blyth (A. W.), Poisons, 1883.
De Candolle, Monographiæ Phanerogamarum, vol. 5, pars 1.

The Librarian reported that the cabinet of slips forming a bibliography of pharmacy, which had been purchased by the Council, had been received, and was available for reference.

The Committee recommended that sundry volumes and parts of the Pharmaceutical Journal be presented to the Smithsonian Institution to complete a set for reference in the United States National Museum, Materia Medica Department.

The Committee recommended that the Journal of the Chemical Society, for March, 1881, February to December, 1882, and the indexes for the same years, be purchased for the Society's Library in Edinburgh.

Curator's Report.

The Curator had reported the attendance in the Museum to have been:—

	Total.	Highest.	Lowest.	Average.
Morning	497	31	9	19
Evening	136	12	1	5

The following donations to the Museum had been received, and the Committee recommended that the usual letter of thanks be sent to the respective donors:—

Specimen of Turtle Oil from the Seychelles. Presented by Messrs. Wright, Layman and Umney.
Specimen of Oil of Petit Grain distilled in Paraguay. Presented by Messrs. W. B. Cranwell and Co.
Thirteen specimens of native remedies used by the Cree Indians of Hudson's Bay Territory. Presented by Mr. W. Haydon.
Specimen of Tupelo tree wood with bark attached. Presented by Messrs. Parke, Davis and Co.
Very fine specimen of Zanzibar Anime. Presented by Mr. E. Fielding.
Specimen of the root of Piptostegia Pisonis. Presented by Messrs. Symes and Hallawell.
Specimen of Cinchona succirubra cultivated in St. Thome, W. Africa. Presented by Messrs. T. Christy and Co.
Specimen of the bark of Strychnos Gautheriana. Presented by Mr. John Sellers.

The Professors had attended and reported satisfactorily of their respective classes.

The report and recommendations of the Committee were adopted.

Mr. Greenish said he should like a Committee, with the sanction of the Council, to consider the question of sending additional copies of the Journal to directors and curators of Museums and Botanical Gardens. At the present time the Journal was distributed very liberally and he himself had furnished several names of persons of the character referred to, to whom it should be sent; but he thought if the Committee went into the subject systematically, the distribution might be a little extended with great benefit.

The President said he would bring the matter before the Committee at its next meeting.

GENERAL PURPOSES.

The report of this Committee included the usual letter from the Solicitor stating the progress of cases which had been placed in his hands.

Two other cases had been considered by the Committee and in one case proceedings were recommended.

The Council, as usual, went into committee to consider this report, and after a long discussion on a case of appeal from the Registrar's decision not to place the name of an applicant on the Register, the report and recommendations were adopted.

Preliminary Examination.

It was resolved that the following certificates be received in lieu of the Preliminary examination:—

The Entrance Examination in Arts of the Faculty of Medicine in the Victoria University.

The Preliminary Examination of the Victoria University.

The Junior Students' General Examination of Owens College.

Analyses of Cinchona Barks.

The President said he had received a communication from Dr. Paul, which would be published in the Journal, containing a report of analyses he had made of the samples of cinchona bark presented to the Museum by the Secretary of State for India.

It was moved by the Vice-President, seconded by Mr. Bottle and unanimously resolved—

"That the best thanks of this Council be given to Dr. Paul for the analyses of bark made by him, and which are of so much interest in connection with the specimens presented to the Society's Museum by the Secretary of State for India."

Reports of Committees—*continued.*

Law and Parliamentary.

The report of this Committee stated that the President had given to it an account of the action he had taken since the last meeting with reference to the draft Pharmacy Bill now in the hands of the Government.

A resolution had been moved in the Committee that immediate steps be taken to organize a deputation to the Lord President of the Privy Council, which had not, however, been carried.

The Council went into Committee whilst the President gave further details on the above subject.

The Council having resumed, it was moved and seconded—

"That the report of the Law and Parliamentary Committee be received and adopted."

Mr. Hampson said he thought the Council had now arrived at an important crisis with respect to the Bill which had been submitted to the Government, and it was quite time the Council should take the initiative in the matter. It had been well represented by the President, and personally the members of the Council felt obliged to him for his activity and zeal, but he believed his hands would be strengthened if the Council publicly expressed its desire to obtain the ear of the Lord President of the Council on this subject. At the Committee on the previous day he had moved a resolution that the Lord President be asked to receive a deputation, so that an opportunity might be afforded to press the claims of pharmacy on his lordship, but that proposal was not accepted. He would, therefore, move—

"That the report of the Law and Parliamentary Committee be received and that the Lord President of the Council be asked to receive a deputation with respect to the draft Pharmacy Bill sent to the Privy Council in February last."

The Council of the Irish Society was moving in the matter, and was anxious that the law in that country should be altered. In England it had been discovered long ago that the Pharmacy Act was defective, and in the interest of the public as well as pharmacy it behoved the Council to take some public steps in the matter.

Mr. Young hoped it would not be needful to have an amendment, because he thought all would agree to this suggestion. He knew the amount of labour the President had bestowed on the matter, and should be satisfied to leave it very much in his hands; but still it was the usual way in this country if you wanted anything to show that you were really in earnest about it. He had been lately struck in reading the life of Lord Palmerston, for in some of his letters he gave accounts of various subjects in connection with his own particular sphere of duty, and referred to the pressure put upon him by different parties. It seemed to him also that he was very much guided by the kind of pressure brought to bear. As an illustration, not long ago, Lord Randolph Churchill, at Edinburgh, seemed to think that it was not necessary to make any more concessions with regard to the franchise, because there were no great meetings or petitions to Parliament about it. He believed that an influential deputation supported by local members of Parliament would have a good effect.

Mr. Greenish also thought the time had arrived when some application should be made to the Lord President with regard to the Pharmacy Bill, and the question arose whether it should be done by the President or by a deputation. He was very much in favour of the old-fashioned mode of deputation, consisting not only of the President and members of the Council, but influential men from different parts of the country. He took it, of course, that the deputation might be introduced by members of Parliament.

Mr. Symes said it was not from any dissatisfaction with the way in which the President had dealt with the matter that he supported the amendment. The President had done an immense deal in the business, but the time had arrived when something additional should be done. He thought it would be very useful to have an influential deputation such as was suggested, especially if it were carried out early in the session.

Mr. Hills said it was the general feeling that there should be a deputation, but the feeling of the Committee appeared to be that Lord Carlingford would be better prepared to inform them what course the Government would be likely to take in two or three weeks than he was at present.

Mr. Williams said he had voted for an immediate deputation and was still convinced that that was the proper course to take. The Council should not wait for Lord Carlingford to move, but should endeavour to move him. The only question which arose incidentally was, whether the deputation should consist of members of the Council only, or should be strengthened from outside.

Mr. Symes said that could be decided when the Council got a reply.

Mr. Bottle recommended a deputation entirely composed of members of the Council. If the Council went outside its own body to get up a large deputation it would look as if an attempt were being made to put pressure on the Government. He believed the Council was bound to its constituents to introduce the Bill in the next session, and in order to do that it wanted to know from the Government whether it was prepared to take up the matter or whether the Council must act independently. The great point was to get the Bill introduced, because if it were deferred the interest which had been awakened during the last five months would die out. He believed there was a large feeling of public interest in favour of amending the law and also amongst medical men, so that there would be a prospect of getting the measure through if it were introduced early in the session. The first thing to know was what the Government intended to do.

Mr. Savage thought a deputation from the Council would be the most appropriate.

The President said the principal point seemed to be whether anyone outside the Council should join the deputation. Perhaps the Council would leave the details in the hands of the Law and Parliamentary Committee to arrange.

Mr. Bottle thought the Council should appoint the deputation.

Mr. Hampson said it would be well for the Committee, who would have to arrange for the deputation, to understand what character it should assume. He was anxious that it should be such as to impress the Lord President of the Council with the importance of the question. On the previous evening someone suggested that the presence of a number of medical men would be important, but he should rather like the Council, if it had confidence in the Committee, to leave the arrangements in its hands. If the deputation was very small it would not be so impressive. It might be strengthened by medical men, members of Parliament, coroners, and so on.

Mr. SCHACHT said if there were too many persons present there might be a risk of having conflicting views.

Mr. GREENISH thought if there were medical men and coroners who had not gone into the various questions thoroughly with the deputation, these persons would be very likely to express views with which the Council could not agree.

The PRESIDENT said he believed that members of Parliament who introduced a deputation were not regarded as part of it.

The VICE-PRESIDENT thought the Council should settle the principle and leave details to the Committee. He did not think it advisable to have a very large deputation for fear of having varied opinions. He should prefer to have as influential a deputation as possible from their own body.

Mr. YOUNG thought it would be right for the Council to nominate the deputation, but it would be well if it were strengthened by gentlemen from different parts of the country. The Committee would take care that the views expressed were in consonance with the Pharmacy Bill which had been drawn up.

Mr. ROBBINS thought it would be very well for different parts of the country to be represented, but better representatives could not be found than those who sat on that Council.

Mr. SCHACHT thought the desire was rather to discuss with the Government whether it would or would not take this matter up from the chemists and druggists' point of view, and it seemed to him it would be rather hindering a free expression of opinion on the part of the minister if the Council were to go accompanied by members of Parliament or any other section of society outside its own particular organization. So far the Council had been in semi-confidential communication with the department, and what was wanted now was to urge upon it the pushing forward of this Bill during the present session. It was hardly desired to urge the matter or bring upon Government that kind of pressure which would imply that there was a large public demand. He doubted whether it would be wise to do more than have a well-selected representative deputation from the Council to confer confidentially with the department as to what might be expected. If the deputation got the cold shoulder it might then be necessary to use a little pressure from without, and under those circumstances outside agitation might be of great service, but he did not think the present was the right time for that purpose. There might be a few points which would require alteration, and he should not like to put any trammels on the utterances of the minister who was approached.

The Council here went into Committee to further discuss this subject. On resuming, the amendment was put and carried in the following form:—

"That the Report of the Law and Parliamentary Committee be received, and that the Lord President of the Council be asked to receive a deputation with respect to the draft Pharmacy Bill sent to the Privy Council in February last. That the members of the deputation and details be left to the Law and Parliamentary Committee to arrange."

DIVISION LISTS.

Mr. GREENISH then moved the following resolution:—

"That the names of the voters for or against any resolution submitted to this Council be published in the Journal reports of the proceedings."

He said his object in moving this was to correct some of the irregularity which had appeared to him to occur in the proceedings. About 1873, Mr. Hampson had proposed a similar resolution, which was considered right and proper, but the Council thought it would be drawing too hard and fast a line. His simple object was to do away with the irregularity. It would have been noticed by members of Council that it was possible to express opinions on a particular subject in language characterized by a felicity of ambiguity which left nothing to be desired, except the knowledge of which way the speaker intended to vote. At the present time every member of the Council saw which way his colleagues voted, but those outside who read the reports did not see which way the members recorded their votes, and as they now possessed the glorious institution of reporting the proceedings of the Council it was right that their constituents should see exactly not only what was said, but which way the persons speaking voted. It would have also a beneficial effect another way. He had observed occasionally that calling for the names had had the most paralysing influence on some members, so that they were utterly unable to hold up their hands. If this rule were general it would reconcile them to the regular reporting of the votes as well as to the remarks which were made. He believed it would be an advantage in every way to have the votes recorded, but he did not like it left to members to call for votes on particular occasions.

Mr. HAMPSON seconded the motion. He thought it would possibly give weight to the proceedings, and those whose votes were recorded might perhaps give a little more consideration to the questions which were discussed, whilst it would do away with any distinction between names being taken at one time and not at another.

Mr. GOSTLING supported the motion. It always appeared to him disagreeable when a little feeling was introduced into the discussion for gentlemen to rise and call for the names to be recorded.

The PRESIDENT said he did not see much harm in the motion, but he thought it would be very inconvenient at times, and it might lead members to call for a ballot under certain circumstances, which they could do under the bye-laws. It was a constitutional practice to take a show of hands, and then, if the decision were challenged, to divide and take the names. He did not think there was anything unconstitutional in the present practice, or anything which did any serious harm. There were occasions, such as the appointment of officers, and others which he could not call to mind at the moment, where it would be inexpedient to publish names. He would rather leave the matter to the good sense of the Council in each case.

Mr. WILLIAMS said there was no doubt it would delay the business. It had always been the practice for any member to have the names taken down if he desired, but he was not aware that it had ever led to any great show of feeling. There might be instances, but it did not last long. If it was held that it looked invidious for a member to call for names to be taken down in a division, by all means adopt the motion. If, also, it was considered necessary that their constituents should know exactly how they voted on every little insignificant occasion, it was another argument in favour of it, but he did not think it was so essential. The names were always taken down in every division of consequence.

Mr. BOTTLE thought an equal amount of inconvenience and personality would arise if this motion were carried. It had occurred to him that if there was a desire that the names should be published, that it should be called for before the division took place. In practice it was otherwise; a show of hands was taken, and then someone who was disappointed at the result asked that the names should be taken down.

Mr. Schacht thought it would be wise to have a rule and keep to it. That was the great recommendation of Mr. Greenish's motion.

The President said there was a rule now, and a constitutional one.

Mr. Schacht said where there was no division no loss of time would take place; but when it came to a question where there was a difference of opinion the taking down of names would not occupy much time. If it were a delicate point, such as had been referred to, it would be easy to introduced the ballot. He agreed that it was rather disagreeable because a man thought he was going to be beaten that he should call for the names to be recorded as a sort of threat. He never paid any attention to it, but it was an offensive thing to hear.

Mr. Greenish said all he desired was that there should be some regularity in the proceedings. He did not care if the names were never taken; but he did not wish it to be in the hands of any members to call for the names at any particular time, when they would not in the ordinary course be taken, thus giving special prominence to a subject which might not deserve it. He had no wish to press the motion on the Council.

Mr. Young thought perhaps Mr. Greenish would be content with having broached the subject.

The President thought it might have the effect desired.

Mr. Schacht did not think it would.

The President said that if names were called for in any invidious manner the matter could easily be balanced by calling for the names in other cases, but he did desire to impress upon the Council that it was unwise to introduce unnecessary restrictions in the conduct of business.

Mr. Greenish withdrew the motion.

Report of Examinations.

Pharmaceutical Society of Ireland.

MEETING OF THE COUNCIL.

The monthly meeting of the Council was held on Wednesday, January 2; the President, Mr. James E. Brunker, M.A., in the chair.

Present:—The Vice-President, Mr. H. N. Draper, F.C.S.; Drs. Collins, Montgomery; Professor Tichborne, Ph.D.; Messrs. Allen, Doran (Bray), John Evans, Grindley, Hayes, Hodgson, McIlwain, Pring (Belfast), Simpson and Wells.

A letter was read from Mr. James N. Hardy, L.P.S., Dublin, calling attention to his former correspondence in reference to a legal point arising on the Pharmacy Act, and pressing for a reply.

The Registrar (Mr. Fennell) said queries arising on Mr. Hardy's letter had been submitted, about two months ago, for the opinion of Mr. Naish, Q.C., Attorney General for Ireland. As yet, however, the learned counsel had not given his opinion.

It was resolved that the Registrar be instructed to communicate with Mr. Naish, asking him to expedite his reply to the queries, and that Mr. Hardy be informed of the steps that had been taken.

Mr. W. H. Brown, of Portadown, wrote inquiring whether the certificate of the Intermediate Education Board would be accepted by the Pharmaceutical Society as an equivalent for their Preliminary examination.

Dr. Collins said that this matter had been discussed by the Councils of the Apothecaries' Hall and the College of Surgeons, and the result was that at both these institutions they had resolved to discontinue their Preliminary examinations and to accept in lieu of them, for the future, the certificates of the Education Board that the candidate had passed in the several subjects required.

Mr. Draper observed, Mr. Brown's letter made no mention of botany, which was one of the subjects required for the Preliminary examination of the Pharmaceutical Society.

Dr. Collins: Of course you will not accept a certificate which does not include all the subjects.

The President: Mr. Brown states in his letter that the Intermediate Education Board do not hold any examination in botany for boys.

Dr. Montgomery apprehended that settled the matter. He proposed that the Council decline to accept the certificate referred to, as it did not include all the subjects mentioned in the curriculum.

Mr. Simpson seconded the motion, which was agreed to.

The President read a letter from Mr. Trevelyan, M.P., Chief Secretary for Ireland, as follows:—

"Chief Secretary's Office, Dublin Castle.
"*December* 27, 1883.

"Sir,—I beg to acknowledge the receipt of your letter of the 24th instant and, in reply, to say that I shall be happy to receive a deputation from the Pharmaceutical Society of Ireland, on Tuesday, January 8, at 1 o'clock p.m.

"Yours faithfully,
"G. O. Trevelyan."

The President said that as he had a notice of motion on the agenda paper in reference to this deputation, he would ask the Vice-President to take the chair while the matter was being discussed.

The Vice-President (Mr. H. N. Draper) then took the chair and—

Mr. Brunker (President) moved—

"That it be an instruction to the deputation about to wait upon the Chief Secretary, to recommend that in any amendment of the law affecting pharmacy or the sale of poisons in Ireland, power shall be given to this Society to license, by examination, a grade of registered druggists, who shall be empowered to sell poisons but not to dispense prescriptions."

He would very much prefer some other member of the Council had brought this question before them, but as no other member had done so he had given the notice in order to bring the matter up for discussion. From what occurred at their last meeting it was necessary the question should be settled one way or other. Until that meeting he was unaware it was such a "burning question" as it appeared to be, or that there was so much difference of opinion upon it. On two occasions, at all events, the Council had expressed a strong opinion upon it and he would have thought that if amongst the general body of the Society there was any strong opposition to it, the opposition would have found expression at the annual meeting, but so far from that, the annual meeting consisted only of the members of the Council and two outside members, which certainly would lead one to suppose there was not any strong opinion held by the outside members on the subject. The matter was before a committee four years ago who, after very full consideration, recommended the establishment of a new grade of druggists, as well as the registration of all existing chemists and druggists who were entitled to continue the sale of poisons under the Act. That proposition was adopted by the Council, but was rejected by the Society at its annual meeting four years ago. The question came again before the Council last year, and, again, the opinion of the great majority was in favour of establishing such a grade as that referred to. He would, in the first instance, observe that this Society was not founded as a Trade Protection Society in any sense of the word. It was formed in order to administer the law as it existed, and if there was any defect in the existing law to suggest a remedy. Now the opinion of every member of the Council he believed was that some change was required. There was no difference of opinion as to the necessity of registering those persons who by the existing Act were entitled, although unqualified, to continue the sale of poisons; but there was a difference of opinion as to the perpetuation of that grade. For his part he (Mr. Brunker) thought the grade ought to be perpetuated with some restrictions and modifications. This Society could not at its present rate of going supply the wants of the public throughout the country. They had on their roll 251 licentiates, but deducting those who were out of the country, the actual number was only about 220. Of those he believed not more than half were in business on their own account, and allowing for those who were residing in Dublin, Belfast, and Cork, they had not at the outside more than between 40 and 50 men qualified as licentiates of the Society to supply the wants of over two hundred towns in Ireland of upwards of 1000 inhabitants. At their present rate of going, therefore, the Society could not for many years supply every town with a qualified pharmacist; and the question arose, would it not be advisable an educated man should be appointed for those towns and villages? There was no doubt whatever the people in those localities wanted men who could sell them such drugs as a pennyworth of arsenic or an ounce of laudanum, and the object of establishing the proposed grade of druggists was that the public should have a guarantee that the persons who sold those things should understand what they were selling—that they should at all events know the difference, for example, between corrosive sublimate and washing soda. He believed at the present day there were hundreds engaged in the trade throughout the country (from the representations the Council had got in reply to their queries) who did not even know that, and the public were completely at the mercy of those people. There were one or two arguments which he believed would be urged against the proposition; one was that when the Society was founded they decided on only having one grade. He, however, did not think that affected the question, for even if they had established two grades of members, the members of both grades would have had the same rights, and both would be entitled to dispense prescriptions, the only difference they could make between them would be that which existed in England, viz., a difference in the standard of examination. Now he did not think any member of the Council would say the Society would be justified in turning men loose on the country to dispense prescriptions on a lower standard of examination than they had at present, nor did he believe that even if they had a higher grade they would find many availing themselves of it. Another argument which certainly possessed some weight was that the establishment of the proposed grade of druggists might tend to encourage illegal dispensing, but he believed that could be avoided by efficient registration. He would suggest that those persons who entered the proposed grade should be required to pay a small annual licence—if it were even as low as 2*s.* 6*d.*—and that lists of those licensed persons should be furnished to the police authorities, so that in each district the police would know who were licensed to sell poisons and who were not.

Mr. Pring (Belfast), in seconding the motion, said after the Pharmacy Act became law they had a discussion in the Council as to the desirability of having two grades of members, but it was decided to have only one, the chief argument being that under their Act as it stood, if they formed two grades they would both possess the same legal rights as to dispensing prescriptions, the only difference would be that a man in the second grade could not call himself a pharmaceutical chemist, but might style himself "chemist and druggist." He (Mr. Pring) believed that it was illegal for a druggist to sell poisons, if they went by the strict letter of the law. He knew a great number of persons in Belfast who considered it a great hardship that the Society had not a second grade of licentiates such as that now proposed—a grade of persons licensed to sell drugs. A great many persons wished to become druggists—to acquire the legal right to sell poisons—who yet did not want to dispense prescriptions; but as the law now stood they must become pharmaceutical chemists, and, in fact, take out a qualification they did not want. For these reasons he seconded the proposition.

Mr. Grindley moved the following amendment:—

> "That inasmuch as the majority of the licentiates of the Pharmaceutical Society of Ireland are of opinion that the proposed grade of registered druggists should include only those at present in business, and should not be extended by examination or otherwise to more than those at present keeping open shop as chemists and druggists, this Council shall not seek power to register such persons for the sale of poisons in Ireland beyond those at present in business."

The meeting of Council at which the proposition to establish this new grade was adopted was attended by only a few members, and it was not unanimous, for the matter was strenuously opposed by two of the members present. He thought this question ought not to be raised at all at any Council meeting, inasmuch as at the Society's annual meeting in October, 1869, it was settled that the grade of registered druggists should not be perpetuated. Of course all existing chemists and druggists,—those who were in business at the time of the passing of the Act,—were entitled to their rights and would not be interfered with; but he (Mr. Grindley) and the body of licentiates for whom he appeared objected *in toto* to this class being perpetuated, as the fact of being licensed to sell poisons would include the right to sell other drugs and would destroy any chance their regularly qualified licentiates had of living. The Act was passed to supply the public with a class of men properly qualified to dispense drugs and compound prescriptions, but if they now established this third grade of men their licentiates would be deprived of all chance of living.

Mr. Pring: What do you mean by a third grade?

Mr. Grindley: There were first the existing "chemists and druggists," those who were in business when the Act passed; secondly, there would be this new grade of registered druggists; and lastly, there were their own regular licentiates, and how were these latter to live if this proposal was carried out? Every man who had passed the Society's examination as a pharmaceutical chemist had expended his time and money on the faith that the Society would protect him and in the belief that only one grade would be established, and never would have gone in for examination if he thought this class of "chemists and druggists" was to be perpetuated. The great majority of their licentiates were opposed to the proposition and between one hundred and forty and one hundred and fifty of them had memorialized the Lord Lieutenant against it.

Mr. Wells seconded the amendment, as he believed the proposition would, if carried out, be destructive of the interests of the great body of the Society's licentiates, injurious to the Society itself and detrimental to the public. The Society had already at one of their annual meetings rejected the proposal. When the matter was brought forward again at a recent meeting of the Council it was not properly explained in the notice paper, and the consequence was only nine or ten members of the Council attended out of the total of twenty-one members. Mr. Grindley and he (Mr. Wells) opposed it at that meeting, but the other seven or eight members present voted for it. Under those circumstances Mr. Grindley and he determined to bring the matter before a meeting of the Society's licentiates in Dublin and let them know what the Council proposed to do. Forty licentiates attended that meeting and were unanimously against it. They also sent circulars to the licentiates in the country, the result being that nearly one hundred and fifty signatures had been affixed to the memorial referred to by Mr. Grindley. He believed the establishment of the proposed class of druggists would increase illicit dispensing Illicit dispensing and compounding were carried on at present, and the Society was unable to prevent it; but if this new class of traders who could style themselves "registered druggists" were established, how could the public distinguish between them and the fully qualified chemist? The result would be the Society would dwindle away. They might have qualified pharmaceutical chemists in the large towns, but in small towns and villages men would not deem it worth while obtaining the qualification for the small advantage they could get by it. The pharmaceutical chemist would be regarded by the public, especially in small towns, much in the same light as people formerly regarded the apothecaries—as persons who charged "tall" prices—and they would suppose the druggist would sell more cheaply and give him their custom. As to the argument that by this proposal they would have a class of educated persons to sell drugs and poisons in the country, the proposition was that they should be examined in the nature and appearance of certain poisonous drugs and chemicals, but he (Mr. Wells) failed to see how that would secure a grade of educated men. Any person with brains could in a short time learn that much; yet that was all that it was proposed to require of him; he need not even know how to write his name. His belief was that the Act as it existed was gradually supplying the country with educated and qualified men to dispense drugs, and numbers of country towns where there never was a qualified dispenser before the Act was passed had one now. In a few years if they continued their system every town in Ireland would have a qualified chemist. He did not see any reason why the sale of poisons should be entrusted to a man who was unfit to make up prescriptions. The better qualified a man was the more careful he was likely to be in dealing with dangerous drugs. At present they heard of arsenic and other poisons being sold in country towns by grocers who were unable to write their names.

Mr. Pring: We want to take the sale out of the hands of such persons.

Mr. Wells said that was all right. He and those whom he represented did not object to that at all. What they objected to was the proposed perpetuation of an inferior grade of sellers of drugs. What they asked was that the names of all existing druggists should be registered, and that while leaving their rights untouched, the Act should provide against the perpetuation of that class of traders.

The Vice-President: Why do you propose to recognize them at present and not continue them?

Mr. Wells: Because you cannot interfere with the existing rights of persons in business. What we say is, register the names of all existing persons in the trade, and then if any unqualified person attempts to sell in future, you can prosecute him. One difficulty the Society has in prosecuting unqualified persons is, because there was no registration of the existing druggists when the Act first became law. Mr. Wells concluded by seconding the amendment.

Professor Tichborne thought as regarded the merits of the proposition there was a good deal to be said for and against. He quite agreed with the remark that in large towns it might be an inducement to illegal compounding, for no doubt many people—especially the lower orders—would not discriminate between a licensed druggist and a qualified pharmaceutical chemist. On the other hand there was no question there were many small towns in Ireland where there was neither an apothecary nor a pharmaceutical chemist keeping an open shop for sale of medicines, and there was no use passing a law which it was impossible to carry out. There must be some people in small towns and villages to sell poisons. Would it not meet the difficulty if it were provided that on a requisition stating that there was no licentiate or qualified man keeping open shop in a town for sale of drugs, the Society should in such cases have the power of licensing a druggist to sell poisons in such town? The first thing they had to consider was whether it was necessary, and if so they ought to ask for it in the interests of the public. That was the light in which Government would regard the question, apart from the interest of any body of men.

Mr. Hodgson observed that if what Mr. Wells proposed was carried out it would be wholly contrary to the spirit of the age, which was decidedly opposed to anything approaching a monopoly. He would never be a party to establishing a huge monopoly, and it never was the intention of the framers of the Act that there should be a monopoly for the sale of drugs and poisons in the hands of the pharmaceutical chemists.

Dr. Collins spoke in favour of the proposition, and observed that ten years ago, when the Pharmacy Bill was before the country, the trade was then quite favourable to what they were now opposing—the establishment of a second grade of druggists—licensed merely to sell, and not to compound medicines.

Mr. Evans said he had received a letter from Mr. Lester, of Cork, who believed the proposed grade would ruin the business of pharmaceutical chemists in small sowns. They would have a lot of half-qualified men telling at ridiculously low prices. He believed the establishmeat of the proposed grade of druggists would be a great mistake.

Dr. Montgomery said the Government would have to look at the question, not from the pharmaceutical chemist's point of view, but in the interests of the public. He believed it would be for the public advantage to have a grade of men qualified to sell poisons, though they might not possess qualifications enabling them to compound prescriptions.

Mr. Simpson said if a man was not sufficiently qualified to compound medicines he was unfit to deal in poisons, for he was ignorant of the character of the articles he was dealing in, and it was unsafe to entrust such a man with the power of selling poisonous drugs. He regarded it as a most unfortunate thing that there was not a registration of the existing chemists and druggists when the Pharmacy Act became law. If that had been done they would not be in the condition they were in now. He intended to vote for the amendment.

The President replied to the observations of the previous speakers, and said of course it was not intended to give any man the proposed new grade of registered druggist unless he could show that he possessed a fair amount of education, besides some technical knowledge of poisons and potent drugs. With regard to Professor Tichborne's suggestion, he quite concurred in the spirit of it, and if he were asked to suggest details, that would be one he would strongly recommend for consideration. If any Bill, however, were introduced at all, it would be a Government Bill, and though of course the framers of it would be likely to consult the opinion of the Council of the Society as to the details of the measure, they would act on their own views and frame such clauses as they thought best in the interests of the public, for this matter must not be regarded in the light of a trade protection question, but as a public question in which all classes of the people were interested.

The votes were:—

For the amendment.—Messrs. Allen, Doran, Evans, Grindley, McIlwaine, Simpson, Wells.—7.

For the original proposition.—The President, the Vice-President, Dr. Collins, Dr. Montgomery, Messrs. Hayes, Hodgson, Pring, Tichborne.—8.

The amendment was therefore lost. The President's proposition was then put, and carried.

A discussion ensued as to the procedure to be adopted upon the proposed deputation to the Chief Secretary, and it was resolved that the President and Dr. Collins should be the speakers to state the views of the majority of the Council, but that as many members of Council should be requested to attend on the deputation as could find it convenient to do so.

In consequence of the lateness of the hour, the remaining business on the paper was adjourned to the next monthly meeting.

Obituary.

Notice has been received of the death of the following:—

On the 5th of December, Mr. John Tribe, Pharmaceutical Chemist, High Street, Chatham. Aged 78 years. Mr. Tribe long held a prominent position in the municipality of Chatham, having, among other offices, filled those of Alderman and Mayor. He was one of the Founders of the Pharmaceutical Society, and served it during several years as a Local Secretary.

On the 8th of December, Mr. William Henry Jackson, Chemist and Druggist, Sutton, Surrey. Aged 57 years.

On the 9th of December, Mr. James Edward Wheeler, Pharmaceutical Chemist, Upper Tollington Park, N. Aged 69 years. Mr. Wheeler had been a Member of the Pharmaceutical Society since 1846.

On the 22nd of December, Mr. Alfred Wright Hardcastle, Chemist and Druggist, Finkle Street, Stockton-on-Tees. Aged 35 years. Mr. Hardcastle had been an Associate of the Pharmaceutical Society since 1873.

On the 23rd of December, Mr. Timothy Grisdale, Chemist and Druggist, Market Street, West Houghton. Aged 48 years.

On the 24th of December, Mr. Edwin Cridland, Chemist and Druggist, Stradbroke, Suffolk. Aged 55 years.

On the 25th of December, Mr. John Ransome Oxley, Chemist and Druggist, Market Hill, Sudbury. Aged 70 years.

On the 25th of December, Mr. John Walton, Pharmaceutical Chemist, High Street West, Sunderland. Aged 61 years. Mr. Walton had been a Member of the Pharmaceutical Society since 1848.

On the 29th of December, Mr. Alfred Uriah Row, Chemist and Druggist, Fore Street, Devonport. Aged 47 years.

On the 30th of December, Mr. George Stuart, Chemist and Druggist, Penny Street, Lancaster. Aged 24 years. Mr. Stuart was an Associate of the Pharmaceutical Society.

On the 1st of January, Mr. Robert Rowell, Chemist nd Druggist, Green Street, South Shields. Aged 47 years. Mr. Rowell had been a Member of the Pharmaceutical Society since 1874.

On the 3rd of January, Mr. Joshua Broughton, Chemist and Druggist, High Street, Wrexham. Aged 75 years.

Correspondence.

Patent Medicines containing Poison.

Sir,—Another case of child poisoning by a patent medicine has lately been reported. Holt's specific for whooping-cough was taken, and it is said to contain antimony. The jury very properly desired to call the attention of the Home Secretary to the sale of patent medicines.

The indiscriminate sale of such medicines, some of which are known to contain opium, antimony, and other potent and deleterious ingredients, is a crying evil, and surely demands the intervention of some law in the matter, either to prohibit altogether or to regulate.

Dispensing chemists ought to co-operate with members of the medical profession and represent to the proper quarter the great danger and unfairness of allowing grocers, oilmen, and others, to sell medicines of which they know absolutely nothing.

It should be enacted that the manufacturers of patent medicines be compelled to state on their bottles whether or not their preparations contain any ingredients dangerous in themselves, or that might prove so in an increased dose; and the retailers of such medicines, who ought to be licensed chemists and no others, would be able to warn purchasers as to the nature of the medicines bought.

Or a more sweeping and justifiable enactment might be made prohibiting manufacturers of patent medicines from making up any ingredients whatever of the nature of what comes under the category of poisons. Why are the makers of patent medicines not held responsible for the melancholy results which sometimes ensue from taking their mixtures? A licensed chemist or medical man would not get off so easily, if a mistake were committed in regard to the dispensing of medicine. An unaccountable leniency is displayed toward the quack.

Let chemists, then, join with medical men in representing this flagrant abuse, and urge the State to interpose on behalf of the innocent beings who are victimized by patent so-called specifics, by herbalists who give poisonous doses of lobelia, as in a case recently recorded, and by unprincipled quacks.

On looking at the list of patent medicine manufacturers, etc., I am astonished at the number who are in no way connected with pharmacy or medicine.

Robert Connell, M.D.

"*Druggist.*"—If possible the prescriber should be consulted.

"*Associate.*"—The substance mentioned is not included in the schedule of poisons.

J. W. S.—Mr. Warren's paper was printed *in extenso* in the *Journal of the Society of Arts* for December 7.

"*Tr. Card. Co.*"—Try Attfield's 'Manual;' but you should remember that chemical experiments and the writing of equations are only useful as means to an end, and are dealt with from this point of view in all good works on chemistry.

"*Coccus.*"—*Liquid Cochineal.*—The following formula is said to yield a preparation that will keep well:—Cocci cacti, potass. carb., potass. tart. acid., pulv. aluminis, āā ℥j; aquæ, ℥viij. Boil the cochineal, carbonate of potassium and water together, then add the alum and acid tartrate of potassium; when cold add half a drachm of rectified spirit to each ounce and filter.

Communications, Letters, etc., have been received from Messrs. Clagur, Robinson, Abraham, Howard, Martin, Hodgson, Apprentice.

LABORATORY NOTES.

BY W. H. SYMONS, F.R.M.S., F.C.S.,

Pharmaceutical Chemist.

Professor Attfield, in his famous Presidential Address to the British Pharmaceutical Conference, describes "the pharmacist proper" as "not only a distributor but a manufacturer or compounder of most pharmaceutical preparations he distributes; the man who can warrant the purity and efficiency of every drug he distributes, either because he has tested it, or because he has made it himself from materials which his professional knowledge tells him to be trustworthy." A glance at the *Pharmaceutical Journal* or the 'Year-Book of Pharmacy' shows that there are such pharmacists and that they give an immense amount of time to the investigation of drugs and chemicals. But, as a rule, it would seem that only the results of very exhaustive researches are published and the little every-day experiences of the laboratory remain hidden in the note-book; whereas, if published, they might be of material assistance to fellow workers and tend to raise the general standard of purity of the articles examined.

In the hope that others may be induced to publish more valuable work, I have selected the following from memoranda concerning the analyses of over two hundred and fifty drugs and chemicals purchased in the usual course of business and examined in my laboratory during the past year.

The processes by which my results were arrived at were, except when otherwise mentioned, the usual recognized methods; but in some few instances processes have been adopted and described simpler, perhaps, than those used for similar purposes in more important chemical investigations, yet sufficiently accurate for purposes of comparison. Care in every case has been taken to avoid giving any result which might be doubtful.

An alphabetical arrangement has been followed as the most generally suitable.

Acidum Hydrocyanicum Dilutum.—Sample No. 1 contained when purchased 1·42 per cent. HCy. Sample No. 2, 1·46 per cent.; after being stored four months in small blue bottles, stopper downwards, in shop cupboard, 1·36 per cent. Both samples contained a notable amount of chlorides.

Acidum Sulphurosum.—When purchased contained 6·72 per cent. SO_2; after being kept in an inverted stoppered bottle and not opened for four months, it contained 5·72 per cent. SO_2. The Pharmacopœia demands 9·2 per cent., but it is well known that practically such a solution cannot be obtained, that 7 per cent. is a good commercial specimen, and that 5 per cent. would be a much better standard.

Acidum Tartaricum.—Three commercial samples were examined; all of them were affected by sulphuretted hydrogen. An attempt was made to estimate the amount of metals present by colorimetric tests, comparing solutions of known quantities of the acids with a standard solution of lead and pure acid, by means of solution of sulphuretted hydrogen. 0·003, 0·004 and 0·010 per cent. were the results arrived at; but the presence of metals other than lead somewhat interferes with the accuracy of the method.

Alumen.—The commercial article is invariably potash alum, but "alumen, B.P.," is still obtainable when specially ordered.

Amylum. — Obtained from three sources. One firm invariably supplies wheat starch; a second for "amylum" sends out maize starch, but for "amylum, B.P.," wheat starch; a third firm sent what on inquiry they said was rice starch, but which I found to be maize starch. Maize starch is quite equal to that of wheat for general pharmaceutical and toilet purposes, and is less often musty.

Bismuthi Subcarbonas.—Five specimens examined; all contained large traces of nitrate.

"*Calamine.*"—Five samples examined. No. 1 contained 90·5 per cent. barium sulphate. No 2, 3, and 4 were apparently similar to No. 1; being unacted upon, to any considerable extent, by acids, they were not further examined. No. 5 treated with hydrochloric acid dissolved with much effervescence, leaving only 2 per cent. insoluble. The acid liquid with ammonia yielded a copious precipitate, almost entirely soluble in excess. Another portion dried at 105° C., lost 0·28 per cent. moisture. At a full red heat it lost 19·46 per cent.

Calcii Chloridum.—A sample of foreign manufacture, examined immediately on opening a sealed bottle, lost 22·4 per cent. at 250° C. Another sample, labelled "pure anhydrous chloride of calcium," lost under similar circumstances 9·94 per cent. The Pharmacopœia directs in the formula for "solution (saturated) of chloride of calcium" 4 ounces of the salt to 5 ounces of distilled water; unless recently dried chloride of calcium be used, a saturated solution will not be obtained. The same authority gives the formula of chloride of calcium dried at 400° F. as CaCl (old style). Fresenius in his 'Quantitative Chemical Analysis,' 6th edition, p. 95, says that when exposed "for several hours to a tolerably strong heat (about 200° C.)" (=392° F.) "the white and porous mass obtained . . . consists of CaCl+2Aq." Roscoe and Schorlemmer also give it as $CaCl_2+2\,H_2O$.

"*Citrate of Magnesia.*"—A commercial sample gave after solution in water—

Free acid reckoned as tartaric . . .	1·3 per cent.
Magnesium sulphate ($MgSO_4 7\,H_2O$) .	12·0 per cent.
Sugar	18·0 per cent.

Creta Præparata.—This preparation, inelegant at all times, has this year been the subject of gross adulteration, a lot having been put on the market containing two-thirds its weight of plaster of paris. Had it been recommended only as "so much whiter" and "greatly superior to the common as a face powder" it would have been bad enough; but what are we to say when we are informed that "This preparation is a great improvement upon the common Prepared Chalk usually sold, and can be strongly recommended as much purer for medicinal purposes"?

Fortunately, a timely warning was given in your columns by Mr. F. Harris Alcock (vol. xiii., p. 1015), and I have reason to believe "this preparation" has not since been offered for sale by London houses. A box of this chalk (?) came into my hands a few days before Mr. Alcock's communication appeared. I found 67·25 per cent. total impurities, the bulk of this being calcium sulphate. It is only justice to the sellers to state that previous and subsequent lots from the same maker and with the same circular have not contained more than 7 per cent. impurities, and we may hope that the writer of the circular was not acquainted with the nature and extent of the adulteration.

Dispensing Measures.

The bottom of the meniscus was taken as the correct reading. The one ounce and two drachm measures being measures of capacity, a sufficient quantity of liquid was delivered into them from a carefully balanced Schuster's alkalimeter, the loss of weight of which was then ascertained. The half-drachm measure was itself balanced and the weighings taken direct. In the case of the tube measure the minims were delivered into a suitable vessel and then weighed. It will be seen that the errors are all in one direction, and may have arisen through the graduator taking some other part of the meniscus. When once the errors are known they are easily guarded against.

The balance used in these investigations was one of Oertling's best (a model of good workmanship); the standard weights were also of ascertained accuracy.

Ferri Arsenias.—Two samples recently purchased yielded respectively 6·5 and 5·47 per cent. of ferrous salt. A small quantity was made in my laboratory according to the Pharmacopœia directions, without special precautions, it being exposed to air during washing and drying, for forty-eight hours, in order to imitate as nearly as possible the supposed conditions of manufacture on large scale; it contained 27·2 per cent. ferrous arseniate. The Pharmacopœia standard is 37·91 per cent.

Ferri Phosphas.—Old stock contained 26·25 per cent. ferrous salt, some recently purchased 37 per cent. The Pharmacopœia standard is 44·75 per cent.

Ferri et Quiniæ Citras.—Fifty grains dissolved in 1 ounce of water, rendered alkaline with ammonia, and shaken with two separate half ounces of ether, yielded 7 grains of alkaloid, which when burnt left no perceptible residue. The same sample by B.P. process gave 6·75 grains alkaloid. Another sample from a different maker, shaken with three lots of chloroform (instead of the ether), yielded 8·3 grains total alkaloid, 7·8 grains being soluble in ether.

Ferrum Redactum.—Old stock contained 32 per cent. of an oxide of iron, some newly purchased only 27·5 per cent. The Pharmacopœia allows as much as 50 per cent.

Hydrargyrum cum Cretâ.—Three new samples examined, all contained traces of mercuric oxide.

Liquorice.—Two samples examined, both yielded 34 per cent. of matter insoluble in water, which under the microscope appeared little else but starch, more or less disorganized.

Linseed.—Several samples examined, all very good as far as freedom from admixture with foreign seeds was concerned, but invariably infested with "acarus farinæ," an extremely pretty object when viewed under a microscope, but most unwelcome among linseed. To stop the depredation all the dust should be sifted off, and with it most of the eggs of the mite. The linseed can then be placed in a tin with a sponge saturated with chloroform, all life is soon destroyed, and a few minutes' exposure to air suffices to remove the odour of chloroform.

Liquor Lithiæ Effervescens.—One trade sample examined from syphon showed 11 grains lithiæ carbonas to the pint.

Liquor Magnesiæ Carbonatis. (Sold in syphons with excess of carbonic acid).—Yielded magnesia equal to 9·8 grains $(MgCO_3)_3$, MgO, $5H_2O$, in each ounce. The Pharmacopœia informs us that it should contain "about 13 grains of carbonate of magnesia in a fluid ounce." A few lines below, under characters and tests, we are told "a fluid ounce evaporated to dryness, yields a white solid residue, which after being calcined weighs no less than 5 grains" of magnesia; this is equal to 11·94 grains of the official carbonate. It is, I believe, however, pretty well understood that 8 grains per fluid ounce is a fair average yield of a product made strictly according to the Pharmacopœia. Kept under pressure in syphons it is rendered available of constant strength.

Liquor Potassæ.—Mr. Woodland, in a paper read before the British Pharmaceutical Conference in 1880, points out the numerous impurities contained in this preparation as found in commerce. The most objectionable of these are chlorides (present to the extent of 0·2 per cent., if we accept the average of ten samples examined by Mr. Woodland) and sulphates. These impurities are generally due to the carbonate of potash, which, as met with in commerce, is always more or less contaminated with them. Bicarbonate of potash on the other hand is one of the purest salts met with in pharmacy; I therefore propose the use of a proportional quantity of this salt in lieu of the carbonate of potash at present used. The formula would read thus:—

Bicarbonate of potassium . . . . 20 ounces,
(or more correctly, 8520 grains).
Slaked lime (washed) . . . . . 12 ounces.
Distilled water . . . . 1 gallon.

Dissolve the bicarbonate of potash in one half the water, and heat the solution to the boiling point in a clean iron vessel, continue the ebullition for ten minutes, then add the lime previously mixed with the remainder of the water, etc.; or it may, where time is no object, be made by the cold process.

Liquor Potassæ Effervescens, B.P.—Various samples purchased at different times during the year. Half a pint of each sample was titrated with volumetric solution of oxalic acid, and the alkali indicated reckoned as $KHCO_3$.

Ten ounces of a sample of London water neutralized 180 grain measures of decinormal solution, equivalent to 0·9 grain $CaCO_3$, or 1·8 grains $KHCO_3$. All the samples examined had been made with hard water, but in the following statement of results no allowance has been made:—

Maker.	Sample.	Grains $KHCO_3$ per ½ pint.
A	1	8·3
A	2	7·5
A	3	8·1
B	1	5·2
B	2	5·0
B	3	5·0
B	4	14·4
C	1	10·5
C	2	10·8

As a rule observation with pocket spectroscope is sufficient to show when this preparation needs further examination, noticing the intensity and persistency of the spectrum. The pocket spectroscope is more convenient to use than a more complicated form of this apparatus. What the microscope is to drugs the spectroscope is to chemicals; each has its sphere of usefulness, and it would be difficult to say which is the more serviceable to the pharmacist.

Liquor Sodæ Chloratæ.—Old stock, 0·852 per cent. available chlorine. Freshly purchased, 1·13 per cent. Some bought a fortnight later from the same firm, evidently recently made, yielded 2·5 per cent., which is the official strength.

Liquor Sodæ Effervescens.—In the examination of these samples decinormal solution of oxalic acid was used. The chalk present in ordinary town water is equivalent to 1·5 grains $NaHCO_3$ per half pint. No allowance was made.

Maker.	Sample.	Grs. $NaHCO_3$ per ½ pint.
A	1	4·9
A	2	5·0
B	1, 2, 3 and 4 each	1·5
C	1	3·1
D	1 and 2	1·6
E	1	8·5
E	2	2·2
E	3	3·9
E	4	1·8
E	5	7·9

The last five samples were all purchased at one time; evidently the bicarbonate of sodium had been put in at hazard.

Soda water having been sold chiefly as a beverage, the absence of soda is certainly not "to the prejudice of the purchaser;" where an antacid is required, potash water should be recommended, as it generally contains alkali.

"*Peroxide of Hydrogen.* Ten volumes."—Four samples examined.

No. 1 contained chloride of barium and was not further tested. No. 2 had an acid reaction, and left on evaporation a notable quantity of sulphate of potassium. No. 3 contained 0·6 per cent. chloride of potassium. No. 4 left scarcely any residue. Five c.c. of Nos. 2, 3, 4, gave respectively, 30, 32 and 40·5 c.c. of gas when mixed in a suitable apparatus with 15 c.c. of volumetric solution of bichromate of potassium; hence they were 6, 6·4 and 8·1 volume preparations.

Potassium Carbonate.—Contained 1·5 per cent. chloride of potassium.

Potassium Nitrite.—Nitrous radicle estimated by means of solution of potassium permanganate.

Sample 1, old stock, deliquescent crystals, contained 86·2 per cent. KNO_2. Sample 2, recently purchased, in sticks slightly discoloured, 84·3 per cent. KNO_2.

Pumice Stone.—This, as is well known, is an impure silicate of aluminium not differing materially in composition from common fire-clay. As it is but slightly attacked, at normal temperature and pressure, by hydrochloric acid, losing but a small percentage of its weight and that chiefly iron, I generally submit the levigated powder, as purchased, to the action of this acid and content myself with that test. On treating a recently purchased sample in this way violent effervescence ensued. Further examination showed that the dried powder lost 12·3 per cent. on treating with dilute hydrochloric acid and that the loss was due chiefly to the solution of carbonate of calcium. The residue consisted of silica and aluminia in abundance, potash and lime in large traces, iron and manganese oxides in smaller traces. The carbonate of calcium was, I suppose, added to improve the colour.

Scammony.—A good article can generally be obtained for a fair price. A lot purchased as virgin scammony contained 83 per cent. resin of characteristic cheesy odour; a sample of a cheaper variety only 40 per cent. of resin, being heavily adulterated with starch.

Sodium Nitrite.—Sample 1, in flat light-brown coloured pieces contained only 6·6 per cent. $NaNO_2$. Sample 2, in small white crystals contained 96·5 per cent. $NaNO_2$.

Syrupus Ferri Phosphatis Co.—Three samples examined, all guaranteed to contain at least 2 grains of phosphate of iron and lime to each teaspoonful. One fluid drachm was mixed with a like quantity of stronger solution of ammonia, the precipitate thoroughly washed, dried and weighed. The wash water was collected and examined for calcium by oxalate of ammonium, iron by sulphide of ammonium, and chlorides by nitrate of silver in the presence of excess of nitric acid.

No. 1 gave 2·1 grains precipitate. The wash water showed traces of calcium, but no iron or chlorides.

No. 2 gave 2·2 grains precipitate. The wash water with the above mentioned tests did not show any traces of either calcium, iron or chlorides.

No. 3 (well known for its elegant appearance and pleasant taste) gave 0·35 grain precipitate. The wash water showed very slight traces of calcium (dried and weighed 0·18 grain $=$ ·15 grain Ca_32PO_4), and iron, also an abundance of chlorides. The reason it surpassed (?) the other samples is thus evident. It could be of very little value medicinally.

The above test is of course rather crude, but time did not permit of a more complete chemical analysis. As a ready means of distinguishing a good "chemical food" from a poor one, I would suggest mixing a sample of each with half its volume of the stronger solution of ammonia. A good specimen will yield a precipitate so copious as to render the whole almost solid; in a syrup containing only traces of phosphate the consistency is scarcely altered.

Zinci Oleas.—Forms a perfectly clear fluid at 81° C. 1·447 gram left on ignition 0·188 gram residue (wholly soluble without effervescence in hydrochloric acid), or 13 per cent. oxide of zinc. Theoretically oleate of zinc should yield 12·9 per cent. oxide of zinc.

In summarizing my results it is interesting to note that out of two hundred and fifty drugs and chemicals examined only one could be considered a case of serious adulteration, viz., creta præparata. The substitute for calamine has been in the market so long as to become recognized by some as calamine. Ferri arsenias, being seldom used, is generally old and oxidized, an improvement would doubtless be to keep it in small quantities in closed tubes freed from oxygen. As to chemical food, good keeping properties and pleasant taste are not the only qualities such an article should have to recommend it. In other cases the impurities were more or less accidental, but might be guarded against by pharmacists demanding analytical certificates with each lot of goods purchased, and not merely trusting to the payment of the best price as a sufficient security for obtaining the best article.

AMERICAN DRUGS.*

BY J. MOELLER,

Botanist and Microscopist of the Imperial Forest Institute, Mariabrunn, near Vienna.

(*Continued from page* 468.)

2. HERBA MICROMERIÆ DOUGLASII (YERBA BUENA).

The part of the plant growing above ground, without flowers. The leaves, oval-shaped, with short leaf-stalks, blunt-pointed and coarsely notched, with nervation running along the rim and with very few tertiary nerves, are given off opposite each other from a square-shaped stem. (Fig. 2.)

Fig 2.

On their upper surface they are nearly smooth, while on the under surface they are thickly dotted with small spots and are covered with hair similar to that on the stem. The largest leaves are 4 cm. long and 3 cm. in width, growing gradually narrower and pointed towards the top. In the axils of the leaf are usually found only thin flower stems, 7 mm. in length; occasionally, however, the calyces are also attached. The latter are usually found to have been torn off in the drug. They are elliptical in circumference, 4 mm. in length, 5 mm. wide, five-toothed, profusely ribbed, with compact skin, hairy externally and internally bare; they envelop four nuts. The plant has a slightly aromatic odour, and a spicy, somewhat bitter taste.

Microscopical Character.—The upper skin of the leaves is furnished on either side with a tough cuticle and has two forms of trichoma. The hair is firm, conical, generally with two cells (Fig. 3), and is sessile on the somewhat prominent enlarged base of the mother cell. The hair gland is disk-shaped with a simple pedicle cell

* Reprinted from the *Therapeutic Gazette* and translated from the *Pharmaceutische Centralhalle*, 1882, Nos. 28, 31 and 33. We are indebted to the courtesy of Messrs. Parke, Davies and Co., of Detroit, for *clichés* of the original engravings illustrating this series of articles.

(Fig. 4) sessile on a tray-shaped cavity on the upper skin of the lower side of the leaf. The cuticle, of very delicate

Fig. 3.

texture, is removed by a vesicle formed beneath it by the accumulation of an intensely yellow gum.

Fig. 4.

The plant from which the *yerba reuma* is derived is the Labiate *Micromeriæ Douglasii*, Benth. (*Thymus Douglasii*, Bth.), and is indigenous in the north-western states of the American Union and in Columbia. It was recently introduced as a drug in California where it is employed as an anthelmintic, emmenagogue and febrifuge.

3. FOLIA CHEKAN.

The dried leaves with a few fragments of leaf-stalks.

The leaves are stiff, although not very brittle; the majority, therefore, when received in good condition are very delicately wrinkled, of a bright green colour, with a yellowish streak, short stem, somewhat curled at rim, and bald on each side. On the superior surface, which to the unassisted eye appears finely granulated, the central nerve only is visible in the majority of leaves; it is only in the larger leaves that secondary nerves may be traced to the circumference. On the lower surface the nerves on all leaves are prominent. The leaves are dotted with transparent points, though in the smaller leaves these points are visible only under the glass.

The leaves are elliptical to oval in shape (Fig 5),

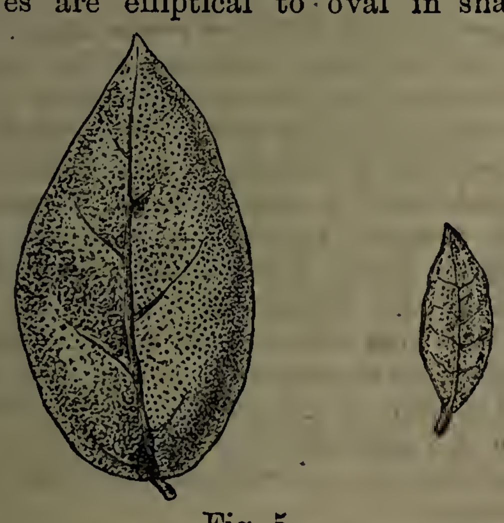

Fig. 5.

pointed at the top and narrowed at the base; they vary in size (from 1 to 4 cm. in length) although the proportion between the length and breadth is constant (1 : 2·5) The leaves are quite odourless; on being rubbed between the fingers they, however, emit an agreeable aromatic odour. Their taste is at first purely aromatic, but is afterwards strongly bitter.

Microscopic Characteristics.—The cuticle is particularly developed on the superior surface of the leaf; a double row of palisade cells constitutes scarcely a third of the thickness of the leaf; the mesophyll consists of irregularly branched cells in an ordinary loosely arranged parenchyma. Large crystal cells are occasionally found among the palisade cells, but seldom or never in the mesophyll. Globular oil cells (0·07 to 0·15 mm. in diameter) with yellowish contents, are disposed under the cuticle of both the upper and lower surfaces.

The plant (*Myrtus Chekan*) from which the chekan leaves are gathered, is an evergreen shrub about 2 m. high, found in the central province of Chili. It differs from *Myrtus communis*, L., chiefly in the fact that its leaves are shorter and broader. Its flowers, also, are composed of but four leaves, are hairy like the calycle leaves, and are rounder than those of the latter. The leaves somewhat resemble smaller buchu leaves, especially those of *Barosma crenulata*, Hook., but the edges of the latter are indentated and so are readily recognized.

The virtues of chekan leaves reside in the tannin and ethereal oil which they contain. Hutchinson has vainly sought to discover an alkaloid in them (*Pharm. Journ.* 1879, p. 653), He discovered tannin which would turn blue in the presence of iron salts, and an ethereal oil, volatile at the ordinary temperature, soluble in chloroform, ether, ethylic and amylic alcohol, insoluble in water, and burning with a bright, white flame.

This plant has long been used under the name of chekan, chequen or cheken, in Chili, where it is held to be powerful aromatic and astringent. The juice of its leaves and young wood, diluted with water has been especially recommended as a collyrium. Don reports remarkable cures of dysentery effected by the liquor in which its bark had been steeped.

Dr. Dessauer, of Valparaiso, has recently been making extensive clinical experiments with chekan leaves. He used an infusion (1 part leaves with 10 parts boiling water), or an extract (produced according to the method prescribed in the United States Pharmacopœia for extracts of cinchona bark), or a syrup (1 part leaves and 2 parts syrup), or finally by inhalation. The results which he has obtained in bronchitis, catarrh of the bladder, and other affections of the mucous membranes, have induced him to ascribe to these leaves tonic, expectorant, diuretic and antiseptic qualities. Linarix attributes these same properties to the oil of common myrtle.

(*To be continued.*)

SALT WORKING AT MIDDLESBOROUGH.*

Among the various works visited by the members of the Iron and Steel Institute during their recent meeting at Middlesborough, were those for raising and preparing salt, undertaken by Messrs. Bell Brothers, the whole process being explained by Mr. T. Hugh Bell.

Although salt has been obtained by evaporating sea-water on the north-east coast for centuries, and local names, such as Saltholme and Salt Beck, would appear to prove early knowledge of the presence of salt, the deposit was only discovered in 1862, when Mr. John Vaughan, of Bolckow and Vaughan, bored for water on the south bank of the Tees, for feeding his steam boilers, and struck the salt at a depth of 1200 feet. The firm subsequently endeavoured to work the deposit by means of a shaft, but soon abandoned it on account of the heavy cost. In 1874, Messrs. Bell Brothers sank a bore-hole on the north side of the river, and found the salt at a depth of 1127 feet, or 73 feet nearer the surface. This deposit exists in the palæozoic series overlying the coal measures, and is about 3000 feet lower, and considerably older,

* From the *Journal of the Society of Arts.*

geologically, than the Cheshire salt, which is found entirely in the triassic series of rocks. The theory of its formation is that the salt water, in isolated basins cut off from the sea or communicating with it by narrow entrances only, was gradually concentrated until it became saturated. The extent of the bed has not been ascertained; and all that is known at present is that it rises to the north, and dips to the south. The thickness, however, as proved by a second bore-hole put down by Messrs. Bell in 1881, is 65 feet, which warrants the estimate that salt is present under Middlesborough in the proportion of 200,000 tons to the acre, which is exactly equal to the annual consumption on the Tyne.

In Cheshire, the surface water trickles through the clay to the gypsum, and flows over the salt, which is thus converted into brine, and only requires being raised to the surface; but, in the Middlesborough deposit, the nature of the strata and the great depth preclude all chance of infiltration. It occurred, however, to Mr. Thomas Bell, that the salt might be raised by allowing fresh water to flow into the hole and become saturated with salt, and then pumping out the brine, without sinking a shaft. The suggestion was quite independent, although this method of working has long been adopted in the east of France. Accordingly, the bore-hole was put down successfully by the rotary diamond drill; and it so happened that a portion of the lowest core was left at the bottom of the hole, leaving an annular space, which has served to receive the lower end of the lining tube. This latter is perforated with holes where it passes through the salt; and the greater portion of its weight is carried by a ring resting on the surface. An inner tube, perforated for a short distance at the bottom, is supported partly by a plate at the bottom and partly by girders at the top. There is an annular space between the two tubes, into which fresh water is allowed to flow. This water makes its way out through the holes in the outer tube, becomes saturated with salt, and rises in the inner tube, but only to such a level that the two columns bear the proportion of ten to twelve, that being the relation of the specific gravities of brine and water. The pump is, however, placed below this level, so as to avoid the necessity for suction. The pump, worked by an engine at the rate of fourteen strokes a minute, lifts from 8 to 9 gallons of brine at each stroke. When the cavity in the salt bed at the bottom of the hole has attained a certain size, the following is supposed by Mr. T. Hugh Bell to be what takes place. A molecule of water, descending the annular space between the two tubes, reaches the upper cavity in the salt, and there finds saturated brine. It, therefore, no longer continues its downward course, but floats on the surface of the heavier fluid, having no tendency to sink until it becomes saturated by coming into contact with the undissolved rock salt. The cavity at the bottom is, therefore, filled with a solution of salt, saturated, or nearly so, with fresh water flowing along its surface, and which gradually becomes saturated in turn. The pump draws the saturated solution from the bottom of the hole, and makes room for fresh water on the surface, so that there is a tendency for the hole to become enlarged at the bottom, and assume the form of a very flat inverted funnel.

The brine is pumped into a reservoir containing 500,000 gallons, and, roughly, between 500 and 600 tons of salt, the salometer standing at about 23°. Thence it flows into twelve shallow evaporating pans, nine of which are heated with coal, and three by the waste gases of the blast-furnaces adjoining, the temperature of the brine being kept at 170°. The salt crystallizes in regular cubes, which float on the surface; and on each cube is formed others, until the whole mass becomes too heavy to float, and sinks to the bottom. Some difficulty was experienced in a thin pellicle forming on the surface, which prevented the crystals from falling, and also arrested evaporation. This was found, on investigation, to be due to gelatinous vegetable matter, which was present in the surface water used; but upon water from the Darlington Waterworks being substituted, the difficulty ceased. Salt is taken out every other day upon platforms, called "hurdles," between the pans, and conveyed in barrows to railway waggons. A scale of sulphate of lime forms on the bottom of the pan, which requires removing at intervals, and also necessitates the laying off and thorough cleaning of the pan every three or four weeks. The twelve pans produce 360 tons a-week of coarse salt, suitable for curing purposes and for chemical works, table salt requiring to be crystallized at a much higher temperature.

COLOURING AMBER.*

For colouring amber it is necessary to find a liquid in which the amber can be heated, and this liquid must fulfil, says Professor Ed. Hanausek, the following conditions:—Its boiling point must lie above 150° C., and it is better if it boils above 200°. The amber must not be attacked by the hot liquid, nor must its physical characters be changed. The liquid must be able to dissolve dyes and not decompose them, or at least not rapidly. It should also be mentioned that the dyestuffs employed must not decompose at 150° or 200° C. Many of the fatty or essential oils, and also solid fats and hydrocarbons which melt below 150°, may fulfil these conditions. The attempt to impart different shades of colour to amber was made with linseed oil. The following pigments dissolve in it without being entirely decomposed at 200° C., viz., dragon's blood, alizarine, purpurine and indigo. Of the aniline colours—fuchsin, aniline violet, methyl green and alkali blue, all refuse to dissolve in pure linseed oil. In carrying out the experiment a weighed quantity was stirred into linseed oil, and the piece of amber to be coloured suspended therein, and slowly heated to 190° or 200° C. The liquid was then kept for some minutes at the temperature of 180° or 200°, after which the source of heat was removed and the hot liquid allowed to cool. After taking the amber out of the oil and cleansing it, it was found to be dyed.

A light or dark reddish-brown can be made with dragon's blood, bright yellow with alizarine, an orange yellow with purpurine, light or dark green, dark blue, and black from indigo. The proportions of indigo that must be taken to obtain the shades mentioned are given as follows:—For light green, $\frac{1}{4}$th of a part of indigo to 100 parts of oil; for dark green, $\frac{1}{2}$ a part to 100; for dark blue, 1 part of indigo to 100; and finally, for black, 4 or 5 parts of indigo to 100 of oil; on heating the oil, the indigo dissolves in it and imparts to it a very beautiful reddish-purple.

By frequently heating these mixtures to 200° C., both the indigo and the linseed oil suffer some change. The oil gets thicker and turns brown, and when heated it no longer assumes such a fine purple colour. A mixture that has undergone this change from heating, colours amber brownish; hence, when it is desired to obtain pure shades of green and blue, it is necessary to frequently change the dye baths or renew them. In dyeing black it is not necessary to suspend the amber in the liquid, for it is coloured more quickly when it lies on the bottom in contact with any undissolved indigo.

If finely pulverized asphalt is put in linseed oil, and the oil heated until it almost boils, a portion of the asphalt will dissolve, forming a brownish liquid and have a distinct green fluorescence. Amber that has been heated in this liquid for a long time to 200° C. acquires a brownish colour and has a slight greenish fluorescence. This fluorescence is, however, much more distinct and striking if the amber is subsequently heated in a mixture of 1 part of indigo in 1000 of oil. All hydrocarbons which are fluorescent themselves can impart this quality to amber.

THE PHARMACIST AS A DISTRIBUTOR OF MEDICINES.

OUR pages this week contain two communications neither of them pretending to great importance in respect to the matter they contain, but both of them worthy of notice because of the spirit by which they are pervaded. They well illustrate the essential difference that should exist between the mode in which the pharmacist carries on his business and that adopted by the grocer or drysalter, and upon which he bases a claim for a higher social status and a more liberal remuneration for his services that are more or less accorded to him by all the thinking portion of the community. It is true it has been urged, and with some force, that in presence of the keen competition by which the pharmacist is beset on every side, he would do well to remember that he is a tradesman and a skilled operator, but not a professional man, and to be satisfied to do the trade part of his calling upon thorough trade principles. This is very good advice as far as it goes, and probably in proportion to the neglect of it by the pharmacist he will be a sufferer. But even the conducting of business on thorough trade principles requires that a man should have a clear perception of the true value of what he sells, and not be betrayed through the confusion evolved in the struggle into vending his wares at less than cost price because a neighbour is selling articles that resemble them at a low figure. And it will only be in so far as the qualified pharmacist remembers that he has something to sell that the unqualified grocer or huckster or keeper of a store has not, and demonstrates this capability to the public by the manner in which he conducts his business, that his experience *quâ* pharmacist will afford him satisfaction or answer to his expectations.

We are perfectly well aware that there is a large amount of business carried on in connection with the drug trade which it would be mere affectation to look upon in this light; business for the transaction of which the most important qualifications are to be able to buy well and to sell well, and the getting or retaining of which is often dependent upon a turn of a trifle in the prices. We have no intention of speaking slightingly of this class of business,—which, indeed, is an important source of income to many chemists and druggists,—but we do not consider that this should come into question as ruling the conditions under which the pharmaceutical part of the business is conducted. We are prepared, however to give the word "pharmacy" a very wide meaning, covering whatever pertains to the dispensing and retailing of medicines, and say in respect to it that the pharmacist cannot in justice to himself or his *confrères* afford to lose sight of the fact that for this service to the public he possesses qualifications that have cost him time, labour and money, which he should therefore neither leave unexercised nor undervalue. Of course, the extent to which the public is likely to recognize or be willing to pay for these qualifications will vary with the locality and other conditions; but care should be taken that if such recognition be not a constant quantity, it shall at least be a reality, since nothing will be so likely to lead to the value of the qualifications being ignored by the public as the light estimation of them by the pharmacist himself.

Mr. SYMONS in his "Laboratory Notes" well illustrates one of the peculiar services that the qualified pharmacist is capable of rendering and should conscientiously render to the public. Professor ATTFIELD was not one whit too stringent in his definition of the "pharmacist proper," as quoted by Mr. SYMONS, as "the man who can warrant the purity and efficiency of every drug he distributes, either because he has tested it or because he has made it himself from materials which his professional knowledge tells him to be trustworthy." So, in his "analyses of over two hundred and fifty drugs and chemicals purchased in the usual course of business" during the past year, Mr. SYMONS has not only been protecting himself, but he has been rendering a service to his customers for which he should, and no doubt will, eventually find remuneration in cash and reputation. A well-known pharmacist, in an able paper that contained many unpalatable truths smartly put and provoked much discussion some two years since, alleged that "the trouble and responsibility of selling an ounce of rhubarb or Gregory's mixture is just about equal to that of selling a quarter of a pound of tea or coffee;" and that "if the educated pharmacist, accustomed to the use of the microscope, can see what appears to him a great responsibility in the sale of such drugs, it is more than the public or the Government can do." With respect to the former opinion we think it is sufficiently disproved by Mr. SYMONS's paper, and if the latter opinion be accepted as correct it is difficult to understand the grounds upon which the enactment of the existing Pharmacy Acts was sought or effected or why it should now be desirable to seek for the establishment of a curriculum. But we entirely demur to the truth of these statements. We believe, on the contrary, that the feeling is rapidly gaining ground amongst the public, and the Government which is a reflex of it, that the distribution of drugs and medicines should, as far as possible, be in the hands of qualified pharmacists, capable of estimating and guaranteeing their identity and quality, and that very few persons, other things being equal, would think it immaterial whether their supplies of medicines were drawn from the chemist and druggist or the grocer. It seems to follow that the future of pharmacy in this country will depend very much upon the extent to which those who practise it succeed, by the judicious and continuous exercise of their special qualifications, in maintaining and intensifying this preference of the public for their services.

The question that is mooted by Mr. C. B. Allen, in his letter, is another that requires careful consideration at the present juncture. The sale of patent medicines, though once a profitable adjunct to was never looked upon as an ideal form of the practice of pharmacy. There are, indeed, a few among our ranks who would wash their hands entirely of the unclean thing; there are, however, more who look regretfully, if not resentfully, towards the portion of the trade that has in the course of the last few years drifted into the hands of grocers, oilmen, linen drapers, *et hoc genus omne.* As long as the pharmacist sells these articles as so many sealed packets, concerning the contents of which he, sometimes ostentatiously, professes to know nothing, he can hardly expect the public to acquiesce in paying a higher price for them to him than to his competitor. But should the exclusive right of dealing in patent medicines containing poisons be conceded to the registered chemist and druggist, as seems not impossible, the position will be very much altered. Then, at least, if not now, if he persists in retailing particular medicines which have supplied occasions for a coroner's jury, without a caution as to the uncertain nature of the compound, he will be incurring a very grave responsibility, and may become involved in unpleasant consequences.

The *St. James's Gazette* reports that at an inquest held in Eastbourne on Monday last, Mr. H. R. Brown, who had been summoned as a juror, but objected to serve on the ground that he was a pharmaceutical chemist in full practice, was told by the coroner that he could not claim exemption on such ground as that. After some discussion Mr. Brown was allowed to leave; but the coroner requested the police to summon him again for the next inquest, intimating that if he then declined to serve he would be fined forty shillings. According to the second section of the Juries Act, 1862, "All registered pharmaceutical chemists . . . . actually practising . . . . shall be and are hereby absolutely freed and exempted from being returned and from serving upon any juries or inquests whatsoever," and provided that care has been taken by the objector at the proper time to ensure that his name has not been improperly inserted on the register, "such ground," when brought within the cognizance of the coroner, would, presumably, be deemed sufficient for claiming and obtaining exemption.

The Eighteenth Chemists' Ball was held at Willis's Rooms on Wednesday last and was attended by nearly two hundred and fifty persons. The chair at the supper was taken by the President of the Pharmaceutical Society, who, in proposing the toast of "Success to the Chemists' Ball," referred to the circumstance that before the institution of the Ball eighteen years ago there had been no general social gathering of pharmacists at which ladies were present, and said that he considered these meetings did much for the *esprit de corps* by promoting good fellowship and mutual respect. It is needless to say that the music was excellent, as it was performed by Mr. Dan Godfrey's band, under the direction of that gentleman. The general arrangements were admirably carried out under the superintendence of Mr. F. W. Warrick, the Honorary Secretary.

* * *

On another page, Mr. Robert Cross, whose name is well known to readers of this Journal in connection with his botanical explorations in South America, gives an account of an interesting experiment made by him in respect to the influence of the electric light upon the development of chlorophyll in plants. We do not think, however, that the results altogether warrant the unqualified tone of his assertion that the electric light will not be found to influence in the remotest degree the development of vegetation. Certainly Mr. Cross's negative results cannot be accepted as sufficient to disprove the positive results obtained by the late Sir William Siemens in 1880, since the experiments do not appear to have been made under similar conditions, the electric light having been supplementary to sunlight in the one case, while in the other an interval of darkness took the place of the sunlight period. Moreover, exposure of the plants to the full glare of the electric light in an enclosed space was expressly stated by Sir William Siemens, in the paper read by him before the British Association in 1881, to influence them prejudicially and not beneficially.

The Legislature of Massachusetts having passed a law for the prevention of the adulteration of food and drugs, the State Board of Health has lost no time before trying to put it into force against the wholesale druggists. One charge was for selling tincture of opium that contained only 0·81 per cent., of morphine, whereas the morphia strength according to the new Pharmacopœia should be 1·2 per cent., and according to that of 1870 0·9 per cent. This case was not tried on its merits, it having been dismissed upon the curious quibble that there was no evidence that the person who sold the drug was an "authorized salesman," though it does not appear whether by this the Court meant that he had not been authorized to act as a salesman by a College of Pharmacy or that he had not been authorized to make the particular sale by his employer.

* * *

Another charge was for selling "citrate of iron and quinine" which did not meet the requirement of the U.S.P. in containing 12 per cent. of quinine. For the defence it was pleaded that the article was not sold as the official preparation, — from which it differed by being in green scales instead of red and being much more soluble,—but as a preparation made by the defendants for many years and marked "English style." On the other hand, the prosecutors urged that an article had been demanded in writing under a Pharmacopœia name and that none but the official article should have been supplied. The Court adopted this view and inflicted a slight fine, against which decision a notice of appeal was given.

* * *

The subject of the inconvenience arising from the large number of special preparations which are now prescribed in the United States was brought under the notice of the American Pharmaceutical Association at its last meeting and referred to a Committee. A suggestion has been made to meet the difficulty by adopting series of "unofficial formulæ," and requesting physicians to give them the preference in prescribing. The Committee appears to have decided to adopt this course, and invites co-operation in the compilation of formulæ for elixirs, proposing, eventually, to deal with fluid extracts, ointments containing petroleum products, wines, emulsions and pills.

* * *

According to the *Chemiker Zeitung* an article has been introduced into commerce, which on account of its low price, fine appearance and solubility has to a large extent been substituted for tartarated antimony in dyeing and printing operations. It proves to be an oxalate of antimony and potassium, which is said to be prepared by saturating a boiling solution of acid oxalate of potassium with freshly precipitated oxide of antimony, and filtering while at the boiling temperature, the salt being deposited as the liquid cools in fine crystals resembling those of the double tartrate. It would appear probable, however, that the same compound is sometimes used in a more questionable manner, since the *Moniteur de la Pharmacie* speaks of parcels of "tartar emetic" having been received by two Paris pharmaciens, containing oxalic acid. In a third sample the oxalic acid is said to have given place to phosphate of soda.

* * *

A Committee appointed at the Conference of Head Masters in 1882 to consider the subject of the inconvenience caused in many schools through the necessity of preparing pupils in the same term for various examinations in which different books are required has come to a decision that will very probably influence future university local and other similar examinations. In view of the fact that the examinations in languages, as at present conducted, often test little more than the knowledge of limited portions of set books, and after consulting a large number of teachers, the Committee recommends that in all public examinations a fair proportion of "unseen work" should be set; and that, whilst not excluding set books, the conditions of all public examinations in languages should be such as to admit the possibility of passing without set books. The desirability of this reform can hardly be disputed, since it would put an end to much unsound teaching which at present has for its object to "cram" the pupil in a certain book, rather than to teach him a language. An illustration of the result was met with not long ago, when one of the candidates in the "Preliminary" wrote out the English rendering of a passage in Cæsar which was not set. Even with considerable vocabulary help and comparative leniency in estimating results, an examination on a passage from an author not previously indicated would be far the more satisfactory test as to a general knowledge of a language.

* * *

The *British Medical Journal*, in an editorial review of the different opinions that have been expressed respecting kairin,—which, by the way, notwithstanding what has been published, it describes as oxychinoline-*methyl*-hydride,—sums up the present state of the question by saying:—"It must be admitted that the prospects of kairin are anything but promising. It has been tried in this country, but as yet has found little favour. It will probably have its day, and then die out, as many remedies of the same class have already done."

* * *

According to the *Times of India* the cinchona bark exported from Ceylon during the three months ending December 31 last, amounted to 1,448,845 pounds, consisting of 1,263,657 pounds of trunk bark and 185,188 pounds of branch bark. This quantity was 183,297 pounds in excess of the quantity exported during the same months in 1882. Nearly two-thirds of this bark (881,212 pounds) was sent to this country. Italy was the next best customer, 414,778 pounds having been shipped to Venice and Genoa. Other continental ports were to share 14,697 pounds between them, and American ports 6946 pounds.

* * *

Among the Bills introduced into Parliament during the coming session there will probably be one promoted by the Council of the Institute of Chemistry, and having for its principal object to effect the incorporation of that association, which is at present a company registered under the Limited Liability Act.

* * *

Our contemporary, *New Remedies*, which has attained a prominent position among the many pharmaceutical journals now published in the United States, has just undergone important modifications in name and style. Henceforth it is to be called the *American Druggist*, and the pages will be considerably increased in size. The latter alteration probably finds its explanation in the growing requirements for "bold advertisement," and there is evidence that there is no intention to neglect this—or, indeed, any other—part of the journal.

* * *

It has been decided by the Paris Municipal Council that a new street opened between the Rue du Faubourg Saint Antoine and the Rue de Montreuil, in the eleventh arondissement, shall bear the name of the veteran chemist Chevreul.

* * *

A meeting of the School of Pharmacy Students' Association will be held on Thursday, January 24, at 8 p.m., when a "Note on Cadmium Iodide" will be read by Mr. F. W. Short, and a Report upon Analytical Chemistry will be made by Mr. C. Thompson on "The Qualitative and Quantitative Separation of Chlorides, Bromides and Iodides."

* * *

The next meeting of the Chemists' Assistants' Association will be held on Wednesday, January 23, at 9 p.m., when a paper on "Unscientific Punishment" will be read by Mr. W. R. Dodd.

Provincial Transactions.

LIVERPOOL CHEMISTS' ASSOCIATION.

The sixth general meeting of the thirty-fifth session was held at the Royal Institution, on Thursday evening, December 20; the President, Mr. Edward Davies, in the chair.

The minutes of the previous meeting were read and confirmed, and the following donations to the Library and Museum were announced:—The *Pharmaceutical Journal* (two numbers), from the Society, and the 'Proceedings of the Liverpool Geological Society,' from the Society.

The Hon. Secretary read a letter from Mr. H. A. Tobias, offering for the acceptance of the Association a complete set of the products of distillation of shale, from the works of the Young's Oil Co., Limited, Addiewell.

A vote of thanks to Mr. Tobias was carried, and the Secretary instructed to acknowledge the gift with thanks.

Mr. A. C. Abraham presented to the Museum a specimen of American bamboo brier root (*Smilax sarsaparilla*). He explained that this plant had at one time been considered, in error, to be the source of the hemidesmus root of commerce, and that probably this arose from its use among the North American Indians having given it a name (Indian sarsaparilla) which was also applied to the hemidesmus. It had come into use recently in combination with other herbs, as a remedy for syphilis, under the auspices of Dr. McDade, and subsequently of Dr. Marion Sims.

Mr. Davies then read a note on—

Alleged Metallic Impurities in Tinned Meats.

BY EDWARD DAVIES, F.C.S., F.I.C.

My attention was recently called to a case of poisoning from eating tinned salmon, the doctor who had charge of the case having attributed the same to *nitrate of tin*. Of course the chemistry of the medical gentleman was, to say the least, peculiar. Nitrate of tin, either stannic or stannous, can only be formed by the action of nitric acid, either on tin or stannous hydrate for stannous nitrate, or on stannic hydrate for stannic nitrate. But there is no nitric acid in the flesh of salmon, and the formation of nitric acid from its nitrogen in the absence of oxygen is a chemical impossibility. Indeed, nitrates of tin are such unstable salts that they could not have endured the heat of preparing the tinned salmon even if they had been purposely added. Whether tin can be taken up by the oil in which the salmon is cooked seemed, however, a possible thing, forming a fatty salt of tin. I have therefore analysed the oil from a tin of preserved salmon, using the cheapest kind. Three hundred grains gave ·03 grain of residue on igniting the precipitated sulphides, of which a part was lead and a trace of tin. This amount is quite insufficient to cause any effect at all. Whether tin in such a form is poisonous is not known. The only salts of tin which have been known to possess poisonous properties are the stannous and stannic chloride. Stannic chloride, as usually prepared, contains free acid, and its strongly irritant effects may be thus partly accounted for, but these salts are not present in tinned meats. Tin in the metallic form is not at all poisonous, and tinned vessels have been in such constant use for cooking purposes that some cases must have been met with, if they could impart deleterious properties to the food. The lead which is almost always present in the tin used for tinning may be supposed to be the active agent. I have analysed tinned beef for this metal and found on the whole of the outside of the meat in a 4-lb. tin ·07 of a grain. The interior of the meat was quite free from this metal.

Lead poisoning from small doses does not cause sudden symptoms. Paralysis is the usual result and not symptoms of irritant poisoning. The amount above stated is quite insufficient to produce any visible effect and the removal of the outside would remove any that might be present.

I also analysed a tin of tomatoes which had apparently suffered partial decomposition. Two ounces gave ·10 of residue when the sulphides were ignited. This was principally tin with a minute amount of lead. The tomatoes were, of course, acid, and I think acid substances should not be preserved in tinned vessels, but even this quantity is so small that I should hesitate to assume that it could be injurious. The bad effects which have in a few cases resulted from the use of tinned meats are, in my opinion, due to decomposition of the meat, owing to imperfect closing or faults in preparation.

The results of my examination are that lead should be carefully excluded in the preparation of the tin plate, and that acid liquids should not be kept in tinned vessels, but that no cases are known in which any injurious effects have been proved to have resulted from metallic impurities in tinned meats.

Mr. Conroy moved a vote of thanks to Mr. Davies, stating that the subject was one of much general interest and importance to the public, and that his own experiments quite confirmed the results arrived at by Mr. Davies.

Mr. A. H. Samuel said that the trade in these tinned provisions had assumed enormous proportions in recent years, and it was very satisfactory to learn on such reliable evidence that there was no foundation for the supposed poisonous effects produced by the metallic vessels employed in packing these meats.

The President then called on Mr. Edward Bevan to read the following paper on—

The Chemistry of Cellulose.

BY EDWARD BEVAN.

It is only fair to state at the outset, and I owe an apology for the fact, that I have but little original matter to communicate, as the work of which this paper is a brief record has already been published in the *Journal of the Chemical Society*, and elsewhere, by my friend Mr. C. F. Cross and myself.

The title of the paper is perhaps somewhat misleading, as I want to speak not so much of cellulose itself as of that peculiar modification known as lignose, examples of which are to be found in wood, various kinds of bast fibres, and in nearly all the different parts of plant structures.

Two distinct views are held by different biologists and chemists as to the nature of lignose: one being that it consists of cellulose, surrounded by what is termed encrusting matter; the other that it is a distinct compound produced by a peculiar modification of the cellulose itself.

In the course of our investigations we have been forced to the conclusion that the latter view is the only one that accords with the observed facts, and it shall be my endeavour to put before you this evening a sketch of the chief results we have arrived at.

Jute was selected as the most convenient type of *lignification*, on account of its great uniformity in character and composition, and its being moreover extremely simple biologically, as compared with wood, etc. Its uniformity is moreover shown by the following numbers, giving the percentage composition, and yield of cellulose of two samples of the same piece. (α) Extreme upper ends; (β) extreme root ends—18 inches from ground.

	α	β
C	47·7 per cent.	47·1 per cent.
H	5·9 per cent.	5·7 per cent.
Cellulose	80·6 per cent.	80·0 per cent.

It was at a very early stage of our investigations that we were led to reject the hypothesis that a lignified tissue consisted of cellulose encrusted with so-called lignin, and to adopt in its stead that by which the tissue was regarded as a true chemical whole. The probability of the correctness of the latter hypothesis, and inferentially, of the weakness of the former view is shown by a study of the action of various reagents on jute.

When jute is heated for some time with 10 per cent. sulphuric acid at about 95° C., a treatment that has but slight action upon cotton or even upon isolated jute cellulose, a large portion is dissolved away. If the residue be examined it will be found to yield practically the same percentage of cellulose as the original fibre, and moreover to possess the same percentage composition.

Now if the jute were simply a mixture of cellulose and encrusting matter, it may be presumed that the action of the sulphuric acid would have been selective, *i.e.*, either the cellulose or the encrusting matter would have been more completely attacked and thus the composition of the residue would have been altered.

Again, if jute be dissolved in ammonia-copper solution and the solution acidified, a precipitate is obtained possessing the properties of the original fibre; being in fact, merely an amorphous modification of it. If this be done fractionally, all the precipitates obtained are similar in character and composition.

The formation of homogeneous "nitro"-derivatives similiar to "nitro"-cellulose affords confirmatory evidence of a similar nature. If jute be treated with a nitrating mixture, such as is used in the manufacture of gun-cotton, explosive products are obtained, from which the original jute can be reproduced by means of certain reducing agents.

In order to obtain some idea of the nature of the body in such close chemical union with the cellulose we studied its behaviour towards various reagents.

The most important is chlorine.

If perfectly dry jute be exposed to dry chlorine gas no reaction occurs, even though the temperature be raised to 150° C. If, however, the jute be previously moistened and then exposed to chlorine a remarkable change takes place, the fibre, originally of a light grey colour, changing to a bright yellow. If this chlorinated jute be boiled in alcohol a large quantity of a bright yellow chlorine derivative passes into solution, from which it can be obtained as an amorphous precipitate on adding water. A large number of analyses of different preparations of this body point to the formula $C_{19}H_{13}Cl_4O_9$. The presence in the molecule of four atoms of chlorine and the resemblance in point of colour, smell and some of its reactions, to tetrachlorquinone seemed to suggest a relationship between the two bodies.

We were thus led at an early stage of the investigation to regard jute and similar substances as compounds of cellulose and a quinone or, as we then termed them, cellulo-quinones.

As our researches progressed we modified or rather extended this view.

If chlorinated jute be boiled in a dilute solution of caustic soda, it is entirely resolved, and a mass of pure cellulose remains. This forms the basis of a method for the rapid and accurate estimation of cellulose.

It is thus seen that by the action of moist chlorine jute is split up into cellulose on the one hand and a chlorinated derivative on the other. The aromatic nature of this body, suggested by its resemblance to tetrachlorquinone, is shown by the fact that on fusion with caustic potash it yields protocatechuic acid and phloroglucin. Though there can be but little doubt about the aromatic nature of the chlorinated derivative, it is somewhat difficult to regard the jute itself as aromatic, and for the following reasons. Dry chlorine has no action on jute, even when presented to it at as high a temperature as 150°; nor if jute be immersed in dry bromine does the least action take place. As we shall see later on, there is good reason to believe that the chlorinated derivative of jute has a very clear connection with the trihydric phenols; now, if the non-cellulose portion of jute were itself of that nature it is most probable that it would be acted upon by both dry chlorine and bromine, especially at elevated temperatures, in the same way that tannin, gallic acid and pyrogallic acid are acted upon.

This, however, is not so, and we were therefore led to regard jute as a compound of cellulose with, what we ventured to call, a potential aromatic body, which, by the action of moist chlorine, is resolved into an actual aromatic body.
